Karageorge and the First Rising (1804–13).—One of the Serbian patriots, Karageorge (*q.v.*; *i.e.*, Karadjordje), fled to the forest to escape death at the hands of the janizaries. Within ten days 2,000 men joined him, and they began attacking Turkish positions. When Karageorge was proposed for the supreme command of the incipient insurrection (Feb. 14, 1804), he declared: "I know myself too well, I am violent . . . ; if I were disobeyed I should not know how to use fair words. I should strike." "All the better," came the reply; "we want a leader whom everyone will fear." The *dahije* tried to negotiate with Karageorge, but after two ineffectual meetings the Serbs seized Rudnik, Valjevo, Jagodina (now Svetozarevo), and Šabac (March–April). They unsuccessfully asked for Austrian and Russian protection. Austrian mediation, at the request of the *dahije*, came to nothing, and in May the Serbs addressed a petition to Sultan Selim III, took Požarevac, and sent a deputation to Russia. A meeting between Karageorge and the pasha of Bosnia, at the latter's request, took place in July, and the Serbs were allowed to capture and behead the four *dahije*. The Serbs then brought their demands before the pasha, but he rejected them.

The Serbian representatives were well received in St. Petersburg; but, for fear of Napoleonic France, the Russian emperor Alexander I decided to uphold Turkey's integrity, and advised the Serbs to send a deputation to Turkey, which they did in June 1805. On learning from the Austrians what the Serbs intended, the Turkish government decided to crush the rising. The Serbs, however, conquered Karanovac and Užice (now Titovo Užice) (June–August). Until then the rising had been directed against the outlawed janizaries, but at Ivankovac, on Aug. 18, 1805, the Serbs for the first time defeated Turkish regular troops. Intoxicated by their successes and aiming now at independence, they organized the Serbian State Council, a supreme administrative and judicial body. They conquered Smederevo in November and sent a deputation to Austria. Though the Serbs were again advised to settle their differences directly with Turkey (February 1806), both Austria and Russia promised their good offices, fearing that Napoleon I's recent victory over Austria (*see* NAPOLEONIC WARS) might induce the Serbs to turn toward France. Napoleon, however, wrote in June 1806 to Sultan Selim that he should use the strongest means to bring the Serbian rebels into subjection. Even so, the Serbs continued their successes; they took Poreč, Paraćin, Ražanj, Aleksinac, Kruševac, the Stari Vlah district, and half of the Novi Pazar district; routed the Turkish regulars again at Mišar and at Deligrad; and finally in December won Belgrade. They had liberated Serbia without outside help.

War broke out between Turkey and Russia at the end of the year. Asked by Turkey for help against Russia, the Serbs replied: "Serbia considers herself an independent state . . . and refuses to take up arms against her brothers and allies" (March 31, 1807). The Russians, however, instead of helping the Serbs, at first asked them to make a diversion; but when Karageorge protested they sent a token force to Serbia. The allies routed the Turks at Štubik, a Serbo-Russian convention was signed on July 10, 1807, and K. K. Rodofinikin arrived as the first Russian diplomatic agent in Belgrade. The Serbs of Serbia made contact with their fellow nationals in Bosnian, Austrian, and Montenegrin territory.

Defeated by Napoleon at Friedland (modern Pravdinsk), Russia concluded the armistice of Slobozia with Turkey (Aug. 24, 1807), in which Serbia was not even mentioned. Karageorge resented such behaviour, and his attitude aroused suspicion in some of his commanders, who wanted more freedom of action for themselves. The Serbian State Council, however, seeing that Russia was attempting to gain exclusive influence, passed the first Serbian constitution (Dec. 26, 1808): this proclaimed Karageorge "first and supreme hereditary leader," who was to command the loyalty of all other Serbian leaders; but it stipulated that his laws and decrees were to be issued through the council, with the common consent of its members, for transmission by it to the military commanders of the provinces. Schools were opened everywhere, including the Belgrade *lyceum* (later university). Karageorge, after informing Russia, rejected an Austrian offer of protection, as well as a Turkish offer of peace.

The Russo-Turkish War restarted in March 1809, and the Russian commander in chief informed the Serbs in May that Alexander I aimed "at the liberation of Serbia from any kind of dependence on Turkey." The Serbs took Sjenica, Suhodol, and Novi Pazar (May–June), but their commanders were torn between Karageorge and his opponents; and the Turks, concentrating a large army in the south, won a victory at Kamenica in June and recovered Soko Banja, Deligrad, Stalać, and Požarevac by the end of August. As the Russian armies were idle, the exasperated Serbs sent a delegate to Napoleon and appealed again to Austria. The Russians, however, invaded Bulgaria (at that time still Turkish territory) in September and the Turks withdrew their armies from Serbia. With renewed confidence in Russia, an assembly of Serbian leaders challenged Karageorge by sending a delegation to the Russian commander in chief, P. I. Bagration, to disavow Karageorge's fruitless approaches to France and Austria. Russia sent 2,500 men to Serbia and in the autumn of 1810 the Turks were defeated at Varvarin and Loznica. Finally, at Karageorge's request, Russia agreed to establish four garrisons in Serbia. To consolidate his position and to silence the opposition, Karageorge convened a leaders' assembly, which passed a new constitution; and before the Russian garrisons reached Belgrade he appointed his first government (Jan. 20, 1811).

On the eve of attack by Napoleon, Russia concluded the Treaty of Bucharest with Turkey (May 1812). Its Art. VIII stipulated an amnesty for all Serbs, the demolition of newly built fortresses, the surrender of old ones, and a limited autonomy, but details were to be negotiated directly between Serbs and Turks. Forsaken again, the Serbs were bitterly disappointed. The opposition held Karageorge responsible, and dissension grew among the leaders. Rejecting a Turkish summons to surrender (July 1813), the Serbs were attacked from three sides by powerful armies and were defeated. Karageorge took refuge in Austria, and on Oct. 7, 1813, the Turks reentered Belgrade. For a fortnight, every Turk was permitted to kill any Serb over 15 years old and to enslave women and children. In a single day 1,800 slaves were sold in Belgrade. After Napoleon I's defeat at Leipzig, the Turks granted a general amnesty.

The Second Rising and Miloš Obrenović I (1814–39).—Miloš Obrenović I (*see* MILOSH), one of the leaders who had not followed Karageorge into exile, was in August 1814 appointed head of three Serbian central districts by the new vizir, Suleiman Pasha Skopljak. When the vizir, to enrich himself, levied new taxes, Serbian leaders sent a delegate to the Congress of Vienna, but Russia was the only power there to feel any interest in Serbia's fate. Russia indeed tried to raise the Serbian question, but failed because of Napoleon's return to France from Elba (March 1815). Then Miloš, who in September 1814 had even helped the Turks to suppress a rebellion, decided to act against them. He summoned all the Serbian leaders to the Takovo church on Palm Sunday and a second rising began.

The Serbs routed the Turkish regulars at Ljubić, Palež (Obrenovac), and Dublje and, in August 1815, took Požarevac. Controlling an area of about 24,440 sq.km., Miloš styled himself "supreme prince and ruler of the Serbian nation" and was recognized as such by the *Skupština* (*see* below) and, in November, by Marashli Ali Pasha, the new vizir; but when the Turks mustered two large armies he realized his weakness and tried to compromise.

The *Skupština* was the National Assembly of the Serbs. Under Miloš, it comprised the 22 district heads (*nahijske starešine*), who were nominated by the prince; and representatives of the town and parish councils, whose members—prominent merchants, priests, and other local notables—were nominated by the district heads. A purely consultative body, it was convened at the prince's pleasure, usually once a year. It was distinct from the leaders' assembly which met regularly twice a year for the discussion of taxes between the prince, the pasha, and the district heads.

In September 1815, Russia threatened military intervention, whereupon the Turks lent Miloš a helping hand. At the beginning of 1816, Serbian demands were partly accepted. Miloš agreed to the supremacy of the Turkish authorities, but soon secured parallelism between Serbs and Turks and finally eliminated the latter. This settlement was guaranteed only by the vizir's word, and Miloš wanted it confirmed by Sultan Mahmud II. He approached the Turks as leader of the Serbs while impressing the Serbs as being a friend of the Turks. Simultaneously, he extended Serbian autonomy, disposed of all rivals, and even had Karageorge assassinated (July 1817)—an act which started the feud between the Obrenović and Karadjordjević (Karageorgevich) dynasties. He then convened the *Skupština* and was recognized as hereditary prince (Nov. 18, 1817).

At last the sultan delivered a decree, but when his representative reached Belgrade and read it to the *Skupština*, the Serbs rejected it (September 1820). As the sultan consistently deferred recognizing Miloš's agreement with the vizir and any solution of the Walachian and Greek problems (*see* EASTERN QUESTION), Russia in March 1826 sent an ultimatum demanding a settlement and fulfillment of Turkey's obligations toward Serbia under the Bucharest treaty. A new Russo-Turkish convention was signed at Akkerman in October, and Turkey undertook to settle the Serbian question within 18 months and to grant Serbia "independence in its interior administration." Turkish negotiations with the Serbs

FIG. 2.—SERBIA 1817–1913

were interrupted by the Russo-Turkish War of 1828–29, which ended with the Treaty of Adrianople (Sept. 14, 1829). As regards Serbia, this treaty reiterated the stipulations of the Akkerman convention, and Turkey undertook to restore the "Six Districts" (Jadar, Crna Reka, Paraćin, Kruševac, and Stari Vlah in the south, and Krajina in the east) which had been liberated during the first rising but later recovered by Turkey. A *hatti-sherif* (imperial edict) was promulgated in Belgrade on Dec. 12, 1830, with a brevet recognizing Miloš as hereditary prince. Serbia became an internationally recognized autonomous principality under Turkish suzerainty and Russian protection; Turkish garrisons were retained only in Belgrade and five other fortresses; and Turkish civilians had to sell their properties in the towns and leave the country or settle inside the walls of the citadels. Turkey, however, still kept the Six Districts. Taking advantage of Mohammed Ali's rebellion in Egypt (1831), Miloš fomented sedition in the Six Districts, gathered troops along their border, and informed the Porte that he was ready to help the rebels if the Turks tried to crush them. Turkey at last gave up, and the union of the Six Districts with Serbia was proclaimed (June 10, 1833), bringing the area of the principality to about 37,740 sq.km. Miloš then paid a state visit to the sultan.

Before achieving his goal, Miloš had solved the agrarian problem by enacting that the land, which the *spahi* tenants of the sultan (*see* above, *Turkish Rule*) had gradually vacated, should belong to those who worked it. In this way he put Serbia's economy on a sound basis and also unwittingly prepared the way for the future peasant democracy of Serbia. He instituted a judicature, formed police forces, and opened new schools. The Serbs agreed with his policy toward the Turks, but in home affairs they were against his despotic tendencies and wanted more representative institutions. Having suppressed five rebellions, Miloš eventually had to let the *Skupština* pass a constitution limiting his powers (1835). Austria, Russia, and Turkey immediately protested against this constitution as too liberal, and Miloš gladly abolished it. Even so, paradoxically, autocratic Russia tried to restrain the prince's Oriental despotism, while liberal Great Britain, in order to build up Serbia into a bulwark against Russian advance in the Balkans, supported the extension of his authority. Finally a new constitution, negotiated in Istanbul between Turkey and Miloš's representative Avram Petronijević (1791–1852), who was under Russian influence, was promulgated by *hatti-sherif* in 1838. A State Council of 17 life members and a cabinet of four were duly instituted. As soon as the constitution became operative (Feb. 24, 1839), the councilors, all of whom belonged to the opposition, were appointed.

The Serbs had sent countless envoys to Istanbul; the Turkish officials had ignored some of them, negotiated with others, and imprisoned others for years or kept them as hostages. Bribery had served the Serbian cause well enough; but the achievement of autonomy was due above all to the political skill, instinctive realism, and indomitable peasant energy of Miloš Obrenović. Temperamentally, however, Miloš could not tolerate having to submit his decisions to a State Council whose members did not depend on him. After trying unsuccessfully to abolish the new constitution by force, he was compelled to end his first reign by abdication (June 13, 1839).

The Period of Oligarchy (1839–58).—Milan Obrenović II, the elder son of Miloš, died after a nominal reign of only 25 days and was succeeded by his infant brother Michael (*q.v.*) Obrenović III. The sultan therefore appointed a regency. Its members represented the so-called "Defenders of Constitutionalism," and it was the embryo of the oligarchy which ruled Serbia for the next two decades. Conflict soon grew up between the Defenders and Prince Michael. The regents, having been sent into exile and then pardoned, finally organized an armed rebellion in complicity with the vizir. The young prince then fled to Austria (Sept. 7, 1842).

On Sept. 14, 1842, the *Skupština* elected Karageorge's son Alexander (*q.v.*) to the throne. Turkey recognized the election, but Russia contested it on the ground that it followed a rebellion instigated by the vizir. At a second election (June 27, 1843), Alexander was again chosen. Two rebellions fomented by Miloš were suppressed in 1844; but the rivalry between the Obrenović and the Karadjordjević dynasty was to continue for 60 years.

Serbia's external relations for the next 12 years were marked by the "Plan" of Ilija Garašanin for foreign policy (*see* GARAŠANIN, ILIYA), by the Hungarian revolution of 1848–49, and by the Crimean War. On the basis of a memorandum by the Polish patriot Prince Adam Jerzy Czartoryski (*q.v.*), Garašanin, the Serbian home secretary, in 1844, developed a plan for a general rising of all Christians under the Turkish yoke and for the creation of a large South Slav state under Serbia's leadership. Originally the plan refrained from anticipating the liberation of the South Slavs of the Austrian Empire; but when the Hungarian revolution broke out Garašanin wanted Serbia to help the Serbs of the Vojvodina, who rose against the Hungarians. The government decided not to intervene, but numerous volunteers flocked to help their kinsmen, and Stefan Petrović-Knićanin (1807–55), a former member of the State Council, became the insurgents' commander in chief. Serbia's choice of neutrality during the Crimean War and Garašanin's connections with the West were rewarded by the Treaty of Paris at the end of that war (March 30, 1856), since it placed Serbia's autonomy under the collective guarantee of the Powers and restricted Turkey's sovereign rights by forbidding armed interference in Serbia without the Powers' consent.

At home, the two main objects of the Defenders were to secure the civic rights of the Serbs and to limit the prince's power. The first was achieved by introducing modern institutions, a competent bureaucracy, and a series of new laws. Whereas the old *Skupština* had never been able to limit Miloš Obrenović I's power, the newly instituted State Council succeeded in limiting Alexander Karageorgević's. Later, however, people realized that their political rights were not necessarily guaranteed by the securing of their

civic rights and that the prince's power was limited not by them, but only by an oligarchy. Furthermore, the stipulations of the constitution were not precise, and the organic laws passed after the constitution were sometimes inconsistent with it. Since the prince's power was more limited by the organic laws than by the constitution, a struggle was inevitable between him and the State Council, which despite its restricted composition was really a kind of representative body of true national leaders. When Alexander asked the council, in 1848, to make the laws conform to the constitution, it made no reply; and his relationship with it became intolerable after 1853, when, under Russian pressure, he dismissed the pro-Western Garašanin (his prime minister and foreign secretary from 1852). In the earlier phases of the Crimean War the prince and the council, which was pro-Russian, observed a truce, but when it became evident that Russia could not win the war dissension was revived. In March 1855, when Alexander informed the council that he was still waiting for an answer to his demand of 1848, he received a flat refusal, and a life-and-death struggle ensued.

Incited by the long-deposed Miloš, Stefan Stefanović-Tenka (1797–1865), the president of the State Council, became the ringleader of a conspiracy to overthrow Alexander; and with a few of his fellow conspirators he organized a new plot against the prince's life (1857). When this plot was exposed, 4 of the 17 members of the council were imprisoned, 6 were compelled to resign, 1 resigned voluntarily, and 2 fell under suspicion. Alexander appointed new councilors; but Russia and France, resentful of the pro-Austrian policy which he had recently adopted, took his action against the old council as a pretext for asking Turkey to send a commissary to Belgrade to settle the conflict. The imprisoned councilors were reprieved and handed over to Turkey, those who had resigned were reinstated and a new government was sworn in. The discovery of the plot had enabled Alexander to strike a major blow at the power of the council, but his victory was short-lived. On Dec. 23, 1858, the *Skupština* deposed him.

Miloš Restored (1858–60).—The *Skupština* which dethroned Prince Alexander recalled Prince Miloš Obrenović I, whose election was recognized by Turkey. The council and the *Skupština* had overthrown Alexander together, but the latter elected Miloš without consulting the former. This created a rift which provided the elements of the first two political groups, based on personal allegiances rather than on any nationwide party or class structure: namely the Conservative supporters of the council, and the Liberal followers of the *Skupština*. The Conservatives, who were called *kajmakanci* (from *kajmakan*, regent) because their leaders had wanted to be elected as regents on the overthrow of Alexander, desired only a change of dynasty, with the legislative power still shared between the council and the prince and with the civil service retaining its entirely conservative character. The Liberals, on the other hand, who were called *dukatovci* because their leaders' anonymous articles appeared in the press over a symbol meaning ducat, wanted to make the *Skupština* the third partner in the legislature and to reform the civil service.

As soon as Miloš reached Belgrade (Feb. 6, 1859), he appointed new councilors and a Liberal government and began dismissing the civil servants. The difference between his populism and that of the Liberals was evident: both wanted a *Skupština*, but Miloš expected it to be dependent on him, while the Liberals wanted it dependent on a strong political party. Miloš, disliking new ideas, asked Jevrem Grujić (1840–1913), his permanent home undersecretary and one of the two Conservative leaders: "If you are responsible, then who am I? I prefer power with responsibility to irresponsibility without power." He estranged the Liberals without attracting the Conservatives, ignored the constitution and the council, and reduced the *Skupština* to a body of illiterate peasants. At the beginning, however, he made himself popular with the peasantry by flattering them. Whereas during his first reign he had been a despot feared by the masses, during his second he was a potentate afraid of them. When he died (Sept. 26, 1860), everyone was tired of his tyranny and demagogy.

Michael Obrenović and Enlightened Absolutism (1860–68).—His son Michael, returning to the throne after 18 years, formulated his program as follows: the liberation of the Balkans; the creation of a large South Slav state led by Serbia; a strict and just application of the law; and economic development. To achieve this he wanted the Serbs to acquire the habit of submitting to law. "As long as a Prince Michael is on the throne," he said, "it is his wish that law be the highest will in Serbia." By law he meant the prince. An era of enlightened absolutism began.

Prince Michael stopped all political persecution and reinstated the dismissed civil servants or gave them a pension, but was unable to reconcile the Conservatives and the Liberals. His first government therefore was a caretaker one, and it passed the laws that he desired. The Council's authority was limited to legislation. The irremovability of the councilors was abolished. The ministers were made responsible only to the prince, not as before both to the Council and to the prince. The government was granted discretionary powers to dismiss and to pension off members of the civil service. The *Skupština* remained as a consultative representative body though its powers were somewhat increased. There was no freedom of the press.

No longer needing to cultivate the Liberals, Michael appointed a Conservative government with Garašanin as prime minister. The latter was thus able to develop and enforce his "Plan," the main object of which was war with Turkey. The strength of the Serbian army was raised from 4,000 men to 50,000 regulars and 40,000 reserves, with a strong artillery; its organization was entrusted to Hippolyte Florentin Mondin, a French army officer. The bill was met by the prince out of his own wealth.

Before starting war, Serbia had to settle the question of the Turkish garrisons. This question was in fact raised by the action of the Turks themselves in June 1862: a brawl between Turks and Serbs queuing for water at a fountain in Belgrade led to firing from the Turkish barracks; and when fighting broke out again later in the day the Turks bombarded the town from the citadel. The Serbian government would have declared war on Turkey but for the intervention of the powers: instead, it negotiated through Jovan Ristić (*q.v.*), its diplomatic representative in Istanbul and he secured the withdrawal of the last Turks. After Prince Michael had paid a state visit to the sultan, the fortresses were surrendered in April 1867. In further preparation for war, meanwhile, Serbia concluded a series of alliances: with Montenegro (1866), with the Bulgarian Revolutionary Committee (1867), with Greece (1867), and with Rumania (1868). The first Balkan League was thus created.

Prince Michael's reign was clouded by two unfortunate incidents. The first arose from the discovery of a plot to overthrow the dynasty. After the court which first tried the accused had found some of them not guilty and had sentenced others for attempting to organize a plot and for *lèse-majesté*, the high court decided that talking in private was not a crime and released them all. The government thereupon put the judges of the high court on trial, and they were all convicted of passing a wrong verdict (1864). The second incident arose from Michael's desire to marry his cousin, Katarina Konstantinović, with whom he was deeply in love. Garašanin, who was against this marriage, was dismissed (1867), and the prince formed a highly unpopular government. Michael now found himself in a most difficult position: the youth of Serbia wanted war with Turkey, but he could not declare war because Russia withdrew support after Garašanin's dismissal; the Liberals, who were in favour of his projected marriage, wanted more political freedom, which he was not willing to concede; and the Conservatives, who supported his strong-handed rule, were against his marrying.

On June 10, 1868, Michael was assassinated. The government suspected Alexander Karageorgević of being behind the plot, but the man who really organized it was the brother of a criminal whom the prince had refused to reprieve.

The Regency for Milan Obrenović IV (1868–72).—Prince Michael having died without leaving a son and heir, the government appointed a provisional regency council until the *Skupština* could elect a new prince. However, Milivoje Petrović-Blaznavac (1824–73), secretary for war, challenged both the regency and the government. He announced by a military *pronunciamiento* that

Milan Obrenović IV, a boy of 14 and the only Obrenović male, had been elected prince. When Milan reached Belgrade, he was greeted by Petrović-Blaznavac and the Army, but the regency and the government were not represented. Eventually they compromised, accepting Milan as prince-elect until his election could be "proclaimed" by the *Skupština*. This was accomplished on July 2, 1868, and Petrović-Blaznavac, Ristić, and Jovan Gavrilović (1796–1877) were appointed regents for Milan. Although elected second regent, Ristić soon took the lead.

The *Skupština* then demanded a widening of its powers and more liberal institutions. The regents drafted a new constitution without consulting either Turkey or the council, with which they still shared the legislative power. The draft was submitted to a Constituent *Skupština* and was passed with a few alterations (July 11, 1869). Its main features were: recognition of the hereditary rights of the Obrenović dynasty; the legislative power to be shared by the prince and the *Skupština* and not, as before, by him and the council; the right to table bills to be reserved to the government, while the *Skupština* could only propose them to the government; the council to remain solely as a consultative body; the government to be responsible only to the prince; the principle of the freedom of the press to be acknowledged; and, finally, judges to be independent but not irremovable. Turkey recognized *de jure* both the hereditary right of the Obrenović dynasty and Serbia's right to pass a new constitution.

Before adjourning, the Constituent *Skupština* in 1870 passed an electoral law, regulations of parliamentary procedure, the law of ministerial responsibility (whereby ministers were not made politically responsible to the *Skupština* but could be required by it to answer certain criminal charges before a special court), the statute of the Council of State (whereby the political State Council was transformed into an administrative Council of State), and an act giving limited freedom of the press. The reforms were not a victory of the people over the bureaucracy, but rather a compromise, and they produced different reactions: the peasants were satisfied that the *Skupština* should have wider powers; the Conservatives disapproved, preferring to continue to support enlightened absolutism; the Liberals, while accepting the new policy, looked forward to further progressive reforms; and a new militant Socialist group led by Svetozar Marković (*q.v.*) was scornfully opposed to such "reforms." Ristić, responsible for the new constitution, avoided stating anything in it which might give the slightest suggestion that the government was dependent on the *Skupština:* Serbia was a constitutional, not a parliamentary, monarchy. Ristić felt it his first duty to protect the Obrenović dynasty and the state, on the one hand, from supporters of the Karageorgević dynasty and, on the other, from Marković's Socialists: he persecuted both sides of the opposition, which considered that he deliberately exaggerated the danger so as to strengthen himself. Meanwhile he paid great attention to education and to the economic development of the country: he balanced the budget and continued to improve the Army (though he slowed down its equipment).

Before being elected regent, Petrović-Blaznavac had promised Austria to "respect Turkey's integrity and to liberate Serbia totally from Russian influence." The relationship with Austria was therefore good, though Ristić managed to prevent Serbia from falling under an exclusively Austrian influence. Since the constitution of 1838 and the sharing of legislative power between the prince and the council had been of Russia's making, the Russian government regarded the constitutional changes in Serbia as a defeat of its own policy and distrusted the new regime. Nevertheless it wanted to draw the young prince closer—and definitely before he came of age. He was invited to visit the emperor Alexander II at Livadia in 1871. This visit resulted in a deterioration of Serbia's relationship both with Turkey and with Austria, and the regency inclined more toward Russia.

As the Serbs of Montenegro adopted a separatist attitude and as Bulgaria became antagonistic to Serbia, the Balkan League which Prince Michael and Garašanin had brought into being gradually fell apart. Ristić in any case had no faith in such a league, believing that the Balkan states, even if united, were too weak to defeat Turkey without outside help, and that any success won with the help of the Great Powers would make Serbia too dependent on them.

Milan's First Governments (1872–75).—When Milan attained his majority (Aug. 22, 1872), the regency ended, but Milan retained Petrović-Blaznavac in office as prime minister and Ristić as minister of foreign affairs. Petrović-Blaznavac died, however, on April 5, 1873, and Ristić then formed a short-lived nonparty government which alienated both Conservatives and Liberals. For various reasons, moreover, Serbia's relationship with Germany, France, Austria, and Turkey became disturbed. To improve the situation, Milan paid visits to Vienna and to Paris. He was well received, but his visits worsened his relationship with Turkey. Ristić, feeling that he was losing Milan's confidence, submitted his resignation (Nov. 3, 1873) in the belief that Milan would not dare to accept it; but Milan, who could not forgive his former guardian for having tied his hands with the constitution of 1869, in fact accepted it. Backed by the League of Three Emperors (Austria, Germany, and Russia), Milan then appointed a Conservative government; in May 1874 he paid a state visit to the sultan. After a general election in October had returned a Liberal majority, discontent grew in the *Skupština*, and, for the first time, it was dissolved. A fresh election, however, in August 1875, gave the same result, and Milan reluctantly appointed a Liberal government.

The Wars of 1876–78 and Independence.—In July 1875 the Serbs of Hercegovina had risen in rebellion against the Turks. The Serbian Liberal government decided to help the insurgents even at the risk of war; but Milan, advised by the League of Three Emperors against intervention, in October 1875 appointed a new government comprising both younger Conservatives and Liberals. As the political groups were divided on the question of war, the decision rested with Milan, who could not curb the growing nationalism incited by the Russian Slavophils (*q.v.*), though officially Russia tried to restrain it. In order to wage war, the prince had to appoint a Liberal government again (May 1876).

Ristić, who became foreign minister, preferred to avoid war, but Turkey rejected his proposal to entrust Serbia with the administration of Bosnia-Hercegovina. The Serbia government then declared war (June 30, 1876), mistakenly believing that the first shot would produce a general Balkan rising and that the Slavophils would force Russia to join. No such rising occurred, and Russia not only abstained from war against Turkey but also agreed, on July 8, that Austria-Hungary, instead of Serbia, should occupy Bosnia-Hercegovina. Even so, the Serbs chose a Russian general, M. G. Chernyaev, to be their commander in chief. His troops, however, in which Russian adventurers outnumbered Serbian officers, were defeated by the Turks at Veliki Izvor on July 18. After an interval of confusion, during which the Russian foreign minister, A. M. Gorchakov, advised a cease-fire and the Russian ambassador to Turkey, N. P. Ignatiev, advised continuation of the war, the Serbs won a victory at Šumatovac. The Great Powers then tried mediation, but Turkey's terms proved unacceptable. Finally the Serbs, after a series of reverses (September–October) appealed to Russia, and on March 1, 1877, peace was concluded on the basis of the status quo.

When Russia in April 1877 declared war on Turkey (*see* RUSSO-TURKISH WARS), Serbia again wanted to fight, but at first received evasive answers from Russia. The Turks, however, halted the Russian advance at Pleven, and Russia then appealed for help. Serbia declared war against Turkey on Dec. 13, and proceeded to liberate large tracts of territory on the southern frontier. Then Russia imposed the Treaty of San Stefano on Turkey (March 3, 1878) without consulting Serbia. This treaty gave Serbia independence and possession of Niš, but only 150 sq.km. of new territory, while a Greater Bulgaria, which Russia needed for further expansion, was created. The opposition of the Great Powers frustrated this plan; and the Congress of Berlin (*q.v.*) in July besides granting Serbia's independence increased the amount of new territory to 3,860 sq.mi. (10,000 sq.km.), adding Pirot, Toplica, and Vranje to Niš. This was achieved through Gyula Andrássy, the Austro-Hungarian foreign minister, after Ristić had come to terms

with him. Disillusioned with Russia, the Serbs now looked to Austria-Hungary. Serbia's unrestricted independence was proclaimed on August 22.

Ristić, appointed prime minister at the head of a new government in October 1878, had to negotiate a railway convention and a trade agreement with Austria-Hungary. The railway convention was signed on April 9, 1880, but the trade agreement raised questions. Even at the risk of a tariff war, Ristić could not sign an instrument which would make Serbia economically dependent on Austria-Hungary. The government was hampered in the *Skupština*, and Milan promised Vienna in September to settle the matter with or without Ristić. When Ristić resigned (Oct. 26, 1880), Milan appointed a pro-Austrian Progressist (younger Conservative) government headed by Milan Piroćanac (1837–97); the Progressists and the Radicals led by Nikola Pašić (*q.v.*) fought an election against the Liberals in December and won nearly all the seats; and on May 5, 1881, a trade agreement which satisfied Serbian peasant needs was concluded with Austria-Hungary.

When Austria-Hungary, Russia, and Germany renewed the League of Three Emperors on June 18, 1881, they divided the Balkans into spheres of influence: Austria-Hungary agreed to the eventual absorption of Eastern Rumelia by Bulgaria, Russia's protégé; and Russia agreed to the annexation of Bosnia-Hercegovina by Austria-Hungary. The Serbo-Austrian secret convention of June 28 was a consequence of these agreements. Negotiated by Milan, its terms, before it was signed, were known only to his foreign secretary, Čedomilj Mijatović (1842–1932). By it, Serbia undertook neither to conclude any political treaty without Vienna's consent nor to tolerate any agitation against Austria-Hungary, while Vienna in return promised to support the Obrenović dynasty, to recognize Serbia as a kingdom, and to sanction Serbian expansion to the south. Later, when its existence was first revealed (1893), this convention was considered humiliating, but it is better regarded as an act of political expediency. Estranged from Russia, Serbia could preserve independence only if Austria-Hungary regarded it as inoffensive.

Milan's Kingdom (1882–89).—Though political groups had existed since 1858, it was only in 1881 that formally organized political parties came into being in Serbia: the Radical Party, the Progressist Party, and the Liberal Party. Acts were passed abolishing censorship, guaranteeing the freedom of the press, the right of public meeting and association, and the irremovability of judges. The Army was reorganized and the number of schools increased, but higher taxation made the government unpopular. The bankruptcy of the Union Générale (Jan. 30, 1882), Serbia's bankers, aggravated a crisis.

Serbia was proclaimed a kingdom on March 6, 1882. The Progressists' policy, however, alienated the Radicals, and a long political fight between the latter and King Milan ensued. The king moreover undermined the prestige of the dynasty by his personal policy and by his notorious private affairs. A general election in September 1883 returned a Radical majority, and the government resigned; but the king appointed first a nonparty government and then again a Progressist one (Feb. 19, 1884), headed by Milutin Garašanin.

The union of Eastern Rumelia with Bulgaria, precipitated by a *coup d'état* in Plovdiv on Sept. 18, 1885, and accepted by Bulgaria, disturbed the Balkan balance of power. Serbia decided to prevent it. Though the war was planned to be a *Blitzkrieg*, Serbia postponed action for more than three weeks because Vienna was officially against war, though Budapest and the Austro-Hungarian minister in Belgrade, Graf Rudolf von Khevenhüller, were in favour of it. When Milan launched his attack (Nov. 14), the Bulgars had already concentrated troops west of Sofia. The Serbs were defeated at Slivnitsa (Nov. 17–19) and driven back across the frontier before Austria-Hungary checked the Bulgars by threatening intervention. The Treaty of Bucharest (March 3, 1886) made peace between Serbia and Bulgaria without any gain to the former. (*See* SERBO-BULGARIAN WAR.)

Milan and the Progressists became unpopular. An election (May 1886) returned a one-seat Progressist majority. In 1887, after Milan and his queen, Natalie, had separated (April 18), the government resigned (June 13). Ristić, who wanted a *rapprochement* with Russia and a new constitution, became prime minister at the head of a Liberal-Radical coalition, which opposed the Progressists in a new election (September). When the Radicals won a majority, they withdrew their support, and Ristić resigned (Dec. 31). For the first time, a homogeneous Radical government was appointed, and a general election in March 1888 resulted in an overwhelming Radical victory. The Radicals, however, passed new laws which the king refused to sanction, and the government resigned (April 26). The king appointed a caretaker government.

With the German chancellor Bismarck's complicity, King Milan had his young son and only child, the crown prince Alexander, abducted from Wiesbaden (July 14, 1888), where he had been in the custody of the king's estranged wife. This act and the king's subsequent divorce (Oct. 24) were serious blows to the prestige of the dynasty. To rehabilitate it, the king initiated a liberal constitution based on a compromise between Liberal, Progressist, and Radical views. He appointed a tripartite Constituent Commission (Oct. 27), over which he successfully presided. An elected Constituent Assembly passed the new constitution (Jan. 3, 1889). This guaranteed civil and political rights, including the freedom of the press; abolished summary courts and the king's power to suspend civil rights in case of emergency; gave the *Skupština* the right to table bills, to receive petitions, to put down questions, to hold inquiries, to pass the budget, and to supervise the government; introduced direct voting by secret ballot; and admitted the principle of local government. Thus Serbia became both a constitutional and parliamentary monarchy. Milan then abdicated (March 6, 1889) in favour of his son Alexander (*q.v.*) for whom he appointed Ristić, Gen. Jovan Belimarković and Gen. Kosta Protić as regents.

The Regency for Alexander Obrenović (1889–93).—Milan having left Serbia, the government resigned, and the regents appointed a Radical government under Sava Grujić (1840–1913). The government passed new laws qualifying the balance between the executive and the legislature to the benefit of the latter; freed political parties from coercion; promoted economic development, and reduced the deficit.

Pressure from Austria-Hungary caused the regents to give an undertaking to comply with the secret convention of 1881. This had been renewed by Milan before he abdicated; but the government was unaware of its existence, and mutual distrust existed between the Radicals and Austria-Hungary. The government was reconstructed in February 1891, and for the first time Pašić became prime minister. Both Ristić and Pašić tried to improve relations with Russia, but while Pašić could do this freely, Ristić was hampered by his knowledge of the secret convention. Even so the young Alexander paid a state visit to Russia. As the radicals became too powerful, the opposition objected that neither person nor property was adequately secured, and that party interest was put before everything else; but the Radicals were more embarrassed by the interference of the king's parents, the divorced Milan and Natalie, and by the public discussion of their quarrel.

Protić, the third regent, died on June 16, 1892. His successor had to be elected by the *Skupština*. Ristić knew that the new regent would be a Radical, but he wanted to avoid having Pašić. To assure Pašić's election, the Radicals proposed a fresh poll and a new *Skupština* to elect the regent. Ristić opposed dissolution and the government resigned (Aug. 21). Despite a Radical majority, a Liberal government under Jovan Avakumović (1841–1928) was appointed. Only then was the *Skupština* dissolved. A political fight between the Liberals and Radicals ensued. A fresh election (March 1893) returned a manipulated four-seat Liberal majority. Then by an unexpected *coup d'état* on April 13, 1893, the young king, although still a minor, proclaimed himself of age, dismissed the two regents and the Liberals, and appointed a Radical government under Lazar Dokić (1845–93). Except for the Liberals, public opinion accepted the change. The Radicals, who had helped the king to make his *coup*, were jubilant.

The Last Decade of Obrenović Rule (1893–1903).—In the first eight months following Alexander's *coup* there were three successive Radical governments. These ratified a new trade agre

ment with Austria-Hungary, reorganized the National Bank, negotiated a new state loan, and brought the former Liberal government to trial. In January 1894, however, the king recalled his father, Milan, a bitter anti-Radical, and brought the first of three nonparty governments to power. On Milan's prompting, he suspended the constitution of 1889 (May 21, 1894) and reestablished that of 1869. While the Liberals and the Progressists were overjoyed, the Radicals were indignant at this retrogressive step, which did irreparable damage to the dynasty.

New elections in April 1895 returned a Progressist majority, and a Progressist government took office in July. It passed several financial and economic laws and secured the appointment of Serbian instead of Greek bishops in Macedonia; but its pro-Russian policy exasperated Austria-Hungary, and Hungary closed its frontier to the import of Serbian live pigs. The "Pig War" worsened after the princes of Bulgaria and of Montenegro paid state visits to Serbia (1896). Replaced in the government by the Radicals, the Progressists decided to dissolve their party (1897) in order to disguise their failure. A new election returned a Radical majority, which tried to revive the Balkan League and signed a political agreement with Bulgaria. The king paid state visits to Sofia, Cetinje, and Athens.

From 1898 to 1900 Serbia was ruled by the king's father through a "strong" nonparty government under Vladan Djordjević (1844–1930). "General H.M. King Milan" was appointed commander in chief of the Army, and became co-ruler with Alexander. Elections in June 1898 returned a docile Liberal majority. Djordjević, blaming parliamentarism for party warfare, passed retrogressive political laws, but promoted economic development. He expanded the army, increased the number of agricultural and technical schools (but decreased the number of elementary and secondary schools); and reduced the budget deficit. He tried unsuccessfully to promote good relations with Turkey and kept up friendship with Austria-Hungary. Russia was against the regime because of King Milan. The government used an attempt on Milan's life (1899) as a pretext for persecuting the Radicals.

While his father and the prime minister were abroad seeking a bride for him, King Alexander announced his betrothal to Draga Mašin, a commoner and widow of questionable reputation. The government resigned (Oct. 11, 1900), and King Milan remained abroad. In the last phase of Alexander's reign government succeeded government: eight in three years. Serbia was flung into Russia's arms, and the emperor Nicholas II acted as best man at the king's wedding (Aug. 5, 1900). The king promulgated a new constitution (April 19, 1901), established a bicameral legislature, and guaranteed freedom of the press and of association; but in 1902 he reverted to reaction. He became the object of widespread aversion, and on June 11, 1903, he and Queen Draga were assassinated.

The Karageorgević Restoration.—An all-party provisional government was formed. The *Skupština* restored the constitution of 1889 and then, on June 15, 1903, elected Peter Karageorgević (*see* PETER I) to the throne. Russia and Austria-Hungary, the former being against any German candidate and the latter against any Russian one, recognized the change. Other powers followed suit, but Great Britain withheld recognition till 1906. When the provisional government resigned, Serbia became a parliamentary democracy, with a predominantly two-party system, being ruled mainly by Radicals, once by Independent Radicals (a party formed in 1901) and, in emergency, by coalition governments. Elections were fought in 1905, 1906, 1908, and 1912. The new regime inherited a budget deficit of 11,500,000 dinars, but in 1904 there was a surplus of 6,500,000. The Army was provided with modern weapons. Confidence revived at home and abroad.

The regenerated Serbia constituted an obstacle to Austria-Hungary's plans for the Balkans. A Serbo-Bulgarian customs union (Aug. 4, 1905) led to a breach in Serbia's trade negotiations with Austria-Hungary and eventually to a tariff war (from Jan. 25, 1906), which compelled Serbia to seek fresh markets, with the result that foreign trade increased by 10,000,000 dinars. On Austria-Hungary's annexation of Bosnia-Hercegovina (*q.v.*) in October 1908, Serbia was strongly inclined to declare war, incited by Russia; but pressure from Berlin and Vienna caused the government to make the humiliating statement that the annexation "does not affect Serbia's rights" (March 1909). The experience, however, strengthened Serbia's determination to form a Balkan alliance. King Peter I paid state visits to the principal European capitals, with the exception of Vienna.

The Balkan Wars (1912–13).—Serbia concluded a treaty of alliance (March 13, 1912) and a military convention (May 12) with Bulgaria, and a political and military convention with Montenegro (Sept. 27); and in October 1912 the three states and Greece declared war on Turkey. (*See* BALKAN WARS.) The Serbs won notable victories at Kumanovo and at Monastir (Bitola) and advanced across Albania to the Adriatic coast. These successes strengthened Serbia's sense of a vocation to play for the South Slavs a role corresponding to that of Piedmont in the Italian Risorgimento. To check the Serbs, Austria-Hungary mobilized, but European public opinion had little sympathy for the Turks, who were compelled to conclude an armistice (Dec. 3). This was followed by a peace conference in London, where all the belligerents found themselves under pressure from the Great Powers to reach an agreement. After six weeks the conference broke up, and war restarted on Feb. 3, 1913. Thanks to 32 Serbian battalions and 92 siege guns, Adrianople (Edirne), which Bulgaria wanted from Turkey, surrendered on March 26. Negotiations were resumed in London on May 20, and the Treaty of London (May 30) gave to the Balkan allies all Turkish territories west of the Enos-Midia (Enez-Midye) line.

While Bulgaria had failed to meet some of its obligations under the alliance, Serbia had fulfilled more than had been stipulated; but in the event Serbia was deprived of an outlet to the Adriatic by Austria-Hungary's veto and by the frontier assigned to the newly created Albania. Serbia therefore demanded that Bulgaria should agree to revise the partition of Macedonia in Serbia's favour and, in accordance with the Treaty of London, proposed that the Russian emperor Nicholas II should act as arbiter. Bulgaria, however, being also in dispute with Greece over Macedonia, on June 28, 1913, decided to attack both Serbia and Greece, without declaration of war. The Serbs defeated the Bulgars on the Bregalnica River (July 9), and Austria-Hungary was held back from intervention against Serbia by Germany and Italy. Bulgaria had to sign an armistice, followed by the Treaty of Bucharest (Aug. 10), which gave to Serbia the contested territories. With Novi Pazar, Kosovo, Štip, Skoplje, and Bitola, Serbia was thus expanded to 87,788 sq.km. Austria-Hungary, dismayed at the Bulgarian defeat, concentrated attention on Albania and, by an ultimatum (Oct. 18), compelled the Serbs to withdraw the troops that they still had there.

World War I.—Incapacitated by ill-health, King Peter I appointed his heir, Prince Alexander (*q.v.*), to be regent (June 24, 1914). The *Skupština* was dissolved. Pašić was canvassing his constituency and the commander in chief, Field Marshal Radomir Putnik (1847–1917), was at Gleichenberg, when Gavrilo Princip (1894–1918), a Bosnian Serb but an Austro-Hungarian citizen, assassinated the Austrian archduke Francis Ferdinand (*q.v.*) at Sarajevo on June 28, 1914. Though Col. Dragutin Dimitrijević (*q.v.*) was one of the inspirers of the plot, the complicity of the Serbian government was never proved: Serbia was exhausted, and the government had every reason to avoid giving offense. Austria-Hungary, however, delivered a formidable ultimatum (July 23). Serbia consented (July 25) to "such collaboration [of Austro-Hungarian officials] as agrees with the principle of international law," and rejected only the demand for the participation of Austro-Hungarian officials in the actual inquiry into the crime, while admitting that even this demand could be met by "communications in concrete cases." Finally, Serbia offered to submit the case to the International Tribunal at The Hague. Austria-Hungary declared war on July 28. (*See* WORLD WAR I.)

The dissolved *Skupština* was recalled, and it unanimously endorsed the government's action. The Austro-Hungarian invaders from Bosnia were routed on Cer Mountain on Aug. 19, 1914, but in September a Serbian offensive across the Sava had to be withdrawn, and further attacks forced the Serbs to retreat eastward

and southward (Belgrade fell on Dec. 1). The Austro-Hungarians, however, were again routed on the Kolubara River; and on Dec. 15 Serbia was cleared of invaders.

On Dec. 7, 1914, the *Skupština* had unanimously resolved that "Serbia's only aim is the liberation and union of all our Serb, Croat, and Slovene brethren." But the policy of the Western Allies, based on expediency, ran counter to Serbia's aim and even to Serbia's integrity as established in 1913. Without the knowledge of Serbia, the Entente concluded the secret Treaty of London with Italy in April 1915, made concrete proposals to Bulgaria in May, and forbade a Serbian declaration of war on Bulgaria in September, when that state was on the verge of attacking Serbia. Though the Allies undertook to provide 150,000 men to support Serbia's ally Greece at Salonika, and though Sir Edward Grey, the British foreign secretary, promised help "without reserve or qualification," there were only 35,000 French and 13,000 British troops (the latter moreover under strict injunctions not to enter Serbia) at Salonika on Oct. 6, when the rupture with Bulgaria occurred. Bulgaria attacked on Oct. 11; and by Nov. 25, Serbia, overcome by combined German, Austro-Hungarian, and Bulgarian forces, was partly occupied by Austria-Hungary and partly annexed by Bulgaria. The retreat of king, government, *Skupština*, and masses of the people with the Army across Albania stands out as one of the great exploits of any war.

Corfu became the seat of the Serbian government. Reequipped, the Army joined the Allies at Salonika. The Serbs conquered Kajmakčalan Mountain on Oct. 4, 1916, and Bitola was liberated on Nov. 19. A formidable rising of the Serbs in the Toplica and Jablanica districts (February–March 1917) was ferociously repressed by the occupying forces. The trial of Dimitrijević and others, at Salonika, on charges of plotting against the regent and the government resulted in political unrest.

The government, the opposition, and the Yugoslav committee on July 20, 1917, signed the Corfu declaration, affirming that Serbs, Croats, and Slovenes constitute one nation and demanding union in a constitutional, democratic, and parliamentary monarchy. In 1918, when the Allies launched the Salonika offensive, the Serbs routed the Bulgars at Dobro Polje (Sept. 16) and liberated Prilep; the French entered Skopje, and Bulgaria capitulated (Sept. 29). Niš, Prizren, and Mitrovica were liberated, and the victorious Serbian Army entered Belgrade on Oct. 31. The war had cost Serbia 23% of its population.

Serbia and Yugoslavia from 1918.—On Nov. 24, 1918, at Zagreb in Croatia, the National Council of Slovenes, Croats, and Serbs, representing the Slavs of Dalmatia, Croatia, Slavonia, Slovenia, and Bosnia, proclaimed the union of their territories, hitherto all subject to Austria-Hungary, with Serbia and Montenegro in one State of the Serbs, Croats, and Slovenes. It then sent a delegation to invite Serbia to adhere to this union. On Nov. 25, however, a National Assembly of the Serbs of Vojvodina, at Novi Sad, voted for the immediate union of their country with Serbia; and on Nov. 26 a Montenegrin Grand National Assembly, at Podgorica, voted for the union of Montenegro with Serbia. Serbia's area was increased to 128,278 sq.km. in the few days before Alexander, as regent for Peter I, on Dec. 1, 1918, in Belgrade, accepted the invitation from Zagreb and so brought into being the Kingdom of Serbs, Croats, and Slovenes (*see* YUGOSLAVIA).

The Treaty of Neuilly (*q.v.*), in 1919, made a slight adjustment to the Bulgarian frontier whereby Serbia obtained (1) a strip of territory between Negotin and Zaječar, (2) the districts of Caribrod and Bosiljgrad, and (3) in the extreme southeast, Strumica. The Conference of Ambassadors, moreover, in 1925, adjusted the Albanian frontier so as to give the monastery of St. Naum to Serbia. These accessions increased the area of Serbia to 130,741 sq.km.; and Serbian territory constituted 20 of the 33 provinces into which the Yugoslav state was divided administratively.

For later history *see* YUGOSLAVIA. In 1929, when the kingdom officially took the name Yugoslavia, the ancient component regions were dissolved into nine *banovine* (administrative provinces), Serbia being then split among five of them. The Yugoslav constitution of 1946 gave to the federal republic of Serbia a smaller area than the Serbia of 1918–29, since Montenegro and the formerly Serbian Macedonia became separate federal republics at the same time.

SERBIAN ORTHODOX CHURCH, the autocephalous national representative in Yugoslavia of the Orthodox Eastern Church (*q.v.*). The Orthodox, who comprise more than a third of the Yugoslav population, are found mostly in Serbia and Macedonia.

The conversion of the Serbs to Christianity is officially placed in the reign of Mutimir (d. *c.* 890), but only after disciples of St. Methodius began their work, with Slavonic translations of the Scriptures and liturgical books, did the Christianization of the Serbs become effective (*see* CYRIL AND METHODIUS, SAINTS). For long the southern Slavs wavered in their ecclesiastical allegiance between Rome and Constantinople, their final adherence to the latter being largely the work of St. Sava (*q.v.*) who became the first archbishop of an independent Serbian Orthodox Church in 1219. The territorial expansion and the prestige of medieval Serbia reached their zenith in the reign of Stephen (*q.v.*) Dushan (1331–55), who assumed the imperial title of tsar; in 1346 the Serbian archbishopric of Peć was correspondingly raised to the rank of patriarchate. Stephen's policy was on the whole to strengthen the church, and his celebrated code (*zakonik*), promulgated at a council of representatives of church and state in 1349, confirmed its privileges.

Stephen's empire fell soon after his death, and in 1389 the overwhelming Serbian defeat at the Battle of Kosovo brought Serbia under Turkish suzerainty. In 1459 the last relics of Serbian independence were extinguished; Serbia became a Turkish pashalik and the patriarchate was abolished. Thereafter the church, administered from Ohrid, was the sole channel for expression of Serbian national spirit and aspiration. The patriarchate of Peć was restored in 1557, and among notable occupants of the see were Jovan, who inspired the "Rebellion of St. Sava" at the end of the 16th century, and Arsenye III, who led a migration of Serbian families into Austria (1690). The patriarchate was abolished again in 1766 and the church remained under the jurisdiction of the ecumenical patriarch of Constantinople until it became autocephalous in 1879, the year after the recognition of Serbia as an independent state. After World War I all the Serbs were united under one ecclesiastical authority and the patriarchate was reestablished in 1920, the patriarch's full title being "archbishop of Peć, metropolitan of Belgrade and Karlovtsi, and patriarch of the Serbs." The Communist government after World War II separated the church from the state and prohibited the teaching of religion except in church buildings.

The supreme authority in the Serbian Church is the Holy Synod, composed of all the bishops, which meets once a year. The patriarch presides also over a standing synod of four members which administers the day-to-day affairs of the church. There are two theological seminaries. The patriarchal journal *Glasnik* is published monthly. There are 22 dioceses, including the extraterritorial one in North America.

The Serbian Church was introduced to the United States as a result of the Serbian immigration that began in the 1890s; the first church was St. Sava's in Jackson, Calif., founded in 1894. The diocese was formally created in 1920 with the appointment of a deputy administrator by the patriarchate and embraced the whole

of Canada, the United States, and Mexico. In 1926 the diocese received its first bishop, and the see was established at the St. Sava's Serbian Monastery, Libertyville, Ill.

SERBO-BULGARIAN WAR (1885), one of the stages in the long-protracted solution of the Eastern Question (*q.v.*). The Congress of Berlin (*q.v.*), in 1878, had given only Niš, Pirot, Leskovac, and Vranje to Serbia, and Serbia was dissatisfied with this award. Considerable fears were entertained lest Bulgaria, which was under Russian influence, should annex areas of mixed nationality (Serbs and Bulgars). Bulgaria claimed Pirot, while the Serbs wished to seize Vidin from Bulgaria. The ruler of Serbia, Milan Obrenovich IV, looked to Austria-Hungary for support and, on June 28, 1881, signed a secret convention with that power. By this convention Serbia undertook to renounce agitation among the Serbs of Austria-Hungary and in Bosnia-Hercegovina in return for a mutual defense agreement, the real meaning of which was that Austria-Hungary would support Serbian claims on territories in the Vardar Valley and elsewhere in the south. Serbia moreover promised to conclude no alliances without the approval of Vienna, which thus obtained virtual control of Serbian foreign policy. With Austria-Hungary's consent, Milan assumed the title of king of Serbia in March 1882.

On Sept. 18, 1885, a *coup d'état* was carried out in Plovdiv (Philippopolis), capital of Eastern Rumelia—the autonomous province constituted south of the Balkan Range under Turkish suzerainty by the Treaty of Berlin (*see* BULGARIA: *History*). The governor was expelled and union declared with Bulgaria. Prince Alexander (*q.v.*) of Bulgaria entered Plovdiv on Sept. 21 and formally accepted the union. Alexander's relations with Russia, however, had not been easy since his election in 1879: neither Conservative nor Liberal ministries had favoured too close a Russian tutelage; the prince in 1883 had been obliged to dismiss two Russian generals, A. V. Kaulbars and L. N. Sobolev, from the Bulgarian service; and the Russian emperor Alexander III blamed the prince for the embarrassments of Russian policy in Bulgaria. When therefore the union of "the two Bulgarias" was declared without Russian approval, the emperor gave orders that Russian officers serving with the Bulgarian Army should be withdrawn (Sept. 23) and informed a Bulgarian delegation sent to meet him in Copenhagen (Oct. 3) that Bulgaria could expect no Russian aid under its existing government.

In Serbia there was considerable agitation for a cession of territory by Bulgaria to compensate Serbia for Bulgaria's enlargement. The Great Powers considered a solution of this kind inevitable, and Russia was not reluctant to see a solution which would detract from Prince Alexander's prestige. G. S. Kalnóky, the Austro-Hungarian foreign minister, was himself unwilling to restrain King Milan, lest a popular rising should overthrow him and install the head of the rival house of Karadjordjević (Karageorgevich), who would almost certainly place Serbia under the influence of Russia. Kalnóky merely asked Milan to delay action until the ambassadors' conference in Istanbul had arrived at a formula to settle the crisis, but Milan was under such pressure at home that he could not wait. He issued a declaration of war against Bulgaria in the night of Nov. 13–14, 1885, and Serbian troops crossed the frontier.

The initial progress of the Serbs was rapid because the Bulgarian Army was not adequately deployed to meet their attack; but, contrary to all expectation, the Bulgars, commanded by relatively junior officers, met and defeated the Serbs decisively in the Battle of Slivnitsa on Nov. 17–19, 1885. On Nov. 26 the Bulgars entered Serbia, and within two days they took Pirot.

The danger now was that Serbia might collapse. The Austro-Hungarian ambassador in Belgrade, Graf Rudolf von Khevenhüller, hastened to Pirot and insisted on an armistice, to which Prince Alexander was unwilling to agree. Austria-Hungary would have been willing to take military action in support of Serbia, but the German chancellor, Bismarck, warned Kalnóky that there could be no modification of the *status quo* in the Balkans without the consent of the powers which had signed the Treaty of Berlin. Peace was concluded at Bucharest on March 3, 1886. Bulgaria surrendered no territory to Serbia.

The result of the crisis gave Russia good reason to be satisfied with Germany. There seemed to Russia to be positive advantages in maintaining the *Dreikaiserbund*, or League of the Three Emperors (Russia, Austria, and Germany), formed in 1881 and renewed in 1884. Austria-Hungary had less reason to be pleased. In 1887, since the *Dreikaiserbund* was not renewed, Russia had to be content with the so-called Reinsurance Treaty with Germany. (R. F. LE.)

SERBO-CROATIAN LANGUAGE, a member of the southern group of the Slavic languages (*q.v.*), is the principal language of Yugoslavia. It is native to the four republics of Serbia, Montenegro, Bosnia-Hercegovina, and Croatia, and serves as an important secondary language in Slovenia and Macedonia. The number of speakers of Serbo-Croatian in Yugoslavia in mid-20th century was over 12,000,000.

The Serbs and Croats are of the same racial stock and speak a single language, but because of nationalistic antagonisms deeply rooted in history they often exaggerate the minor regional differences in an attempt to prove that there are two languages. The Catholic Croats lived for centuries under Venetian or Austro-Hungarian rule, while the Orthodox Serbs enjoyed a brief period of independence within the sphere of Byzantium and then were subject to the Turks for five centuries. Consequently the Croat writes his language in Roman letters, calling it Croatian, while the Serb uses the Cyrillic alphabet and calls the language Serbian (for a table of the Cyrillic alphabet, *see* SLAVIC LANGUAGES). The Croats speak a western type of dialect, but not all Serbs speak eastern dialects. In vocabulary it is possible to point out some words which are specifically Croatian and others which can be called Serbian, yet nearly always where lexical doublets exist, both forms are known and understood all over the country.

History.—The earliest surviving Serbo-Croatian texts date from the 12th century. In Serbia, the local variant of Church Slavonic was in use until Russian Church Slavonic books were adopted at the end of the 17th century. During the following decades the Serbs worked out a compromise style called Slavono-Serbian. In Croatia the chief written language was Latin, but nonetheless in some areas the Croats wrote their own language with Glagolitic letters, using their own style of Church Slavonic for literature, and the local *ča*-dialects (*see* below) for records and legal documents. Dalmatian poets wrote in the *ča*-dialect in the 16th century, but the *što-(i)je* dialect of Dubrovnik soon became the literary language. Attempts in the 18th century to base a literary language on the *kaj*-dialects gave way to enthusiasm for an artificial "Illyrian" language which was to unite all south Slavs. At this time a Serb, Vuk Stefanović Karadžić (1787–1864) began to write in his native *što-(i)je* Hercegovinian dialect. He worked out an excellent phonemic orthography, adapting Cyrillic letters to make an alphabet truly suited to the language. Vuk's dialect was the one spoken by the largest number of people, it was central, in a sense a compromise among peripheral dialects, and moreover it was close to the language of Dubrovnik literature. After long controversy, a group of leading Croat and Serb writers formally accepted Vuk's language in 1850, but dissension about details continued. Since the end of the century, the *e*-dialects have been used in the Serbian east, while the rest of the country has retained Vuk's *(i)je* forms.

Classification.—Serbo-Croatian is joined to its South Slavic neighbours by transitional dialects, in the east and south to Bulgarian and Macedonian, and in the northwest to Slovene. It is closer to Slovene, however, in that both have retained full nominal declensions and vocalic systems which distinguish long from short and rising from falling vowels, whereas Macedonian and Bulgarian have virtually lost the case system and have neither length nor intonation as distinctive features of the vowels.

The three major Serbo-Croatian dialects are named *što*, *ča*, and *kaj*, according to their respective interrogative pronouns for "what?"

The *što* dialect covers the largest area and is the basis for the

standard language. The *ča* dialect, formerly spoken widely in the west, is rapidly disappearing, though it can still be heard on the Dalmatian islands, in much of Istria, and in a few spots on the mainland. It is important for historical linguistics because it has preserved with great fidelity the accent on the same syllable that bore it in Common Slavic. The *kaj* dialect is spoken in most of northern Croatia, including the Zagreb region. It seems once to have been a part of Slovene, but during the last millennium its character was changed because of strong influence first from the *ča* and then from the *što* dialects.

Što-Serbo-Croatian is characterized by the development of Common Slavic *ǫ* to *u*, *tj* and *dj* to the strongly affricated palatal stops *ć đ*, syllabic *l* > *u*, and, generally, post-vocalic *l* > *o*, and both *ŭ* and *ĭ* > *a*. There is a strong tendency to avoid difficult consonantal clusters, either by inserting a vowel or by dropping one of the consonants. The aorist and imperfect tenses are regularly used in the east but restricted to the written language in the west. In the east the infinitive is usually avoided, being replaced by *da* plus present tense.

The subdivisions of the *što* dialect are generally defined by a combination of criteria, chiefly the development of Common Slavic *ě* and the degree of innovation in the accentual system. In the east *ě* > *e* (**dětę* "child" > *dête*, **děca* "children" > *dèca*), in the west *i* (*dîte*, *dìca*), and in the intermediate area *ije* if long and *je* if short (*dijète*, *djèca*). The original geographic division has been obscured by mass migrations of *(i)je*-speakers to the west, and in some areas (especially Bosnia) Catholics and Muslims use the *i*-forms, and members of all three religions the *(i)je*-forms. Isolated dialects have a mixed development (*i/je* or *ē/je*) or have maintained a six-vowel system where *ě* has not fallen together with any other vowel. In accentuation, there is a general tendency to shift the stress one syllable toward the beginning of the word. Conservative dialects have admitted shifts rarely or not at all, but most dialects have carried the shift through in many or all possible cases. The standard language has the newer accentuation, and for *ě* either *e* (Serbia and the Vojvodina) or *(i)je* (Montenegro, Bosnia-Hercegovina, Croatia). The vocalic system here includes *i e a o u* and syllabic *r*, all of which may occur long or short, with rising or falling intonation. Rising intonation never occurs in a final syllable. There can be only one rising syllable in a word, and it automatically receives the stress, which is weak. If there is no rising intonation, the stress falls on the first syllable.

SERENA: *see* LA SERENA.

SERENADE (French, "evening music"), a musical composition which was originally a song of courtship. The serenade to Zerlina, "Deh! vieni alla finestra," in Mozart's *Don Giovanni*, is an outstanding example in opera. Losing its association of courtship, the term serenade was applied about 1770 to instrumental works for a small ensemble in several movements, similar in kind to works of the same period entitled cassation, divertimento and notturno. The sequence of movements, which was indefinite, included marches, minuets, and sonata movements, and resembled that of the suite (*q.v.*). Mozart's *Haffner* serenade is one of the finest examples. Later, in works by many composers from Beethoven to Sir Edward Elgar, Richard Strauss, and Arnold Schoenberg, the term was applied to works in several movements for small orchestra, a solo instrument, or wind or string instruments.

SERER, an industrious Negro people of Senegal, south of the railway between Thiès and Kaffrine, numbering about 500,000 in the 1960s. Traditions indicate that their ancestors moved westward under pressure from Wolof, Malinke, and Fulani (*qq.v.*). The dialects of Serer belong to the West Atlantic group of languages (*see* AFRICAN LANGUAGES: *The Niger-Congo Family*). Some similarities in vocabulary are found between Serer and Fulani.

The compact Serer villages have round or square thatched houses of reed or millet stalks. Feud was important in their former political organization, and law and order were maintained by supernatural sanctions; *e.g.*, trial by ordeal and formal cursing. They lack the caste system of the Wolof, and are organized in exogamous matrilineages, though a wife joins her husband's community. They have a mixed economy, keeping cattle, growing millet for food and peanuts for sale; crop rotation is practised, and fodder is gathered from *Acacia albida* trees. Property, such as land or cattle, is vested in the matrilineage head. Most Serer are pagan, with few converts to Islam and Christianity. Spirits of the dead are appeased or invoked; graves are covered with thatched roofs, a man's being marked with a bow and arrow, a woman's with mortar and pestle; special ceremonies are held for rainmaking.

SERFDOM AND VILLEINAGE, terms used to describe the status of peasants who possessed their own means of subsistence but lacked personal freedom. One of the problems facing the historian of serfdom is that of definition. For some authorities, serfdom is an institution of public law requiring for its existence certain legal definitions separating the serf from the free man. For others, serfdom is a social condition that may or may not be defined in law. Since social realities often exist for long periods of time without receiving legal recognition, it follows that legally defined serfdom would not necessarily coincide chronologically or geographically with the serfdom that is defined in sociological rather than legal terms. One would expect the social condition to appear before its legal definition and to decline in practice before it disappeared from the law. This happened in England, where in law there does not seem to have been an intermediate position between freedom and slavery until the 12th century, although servile social conditions existed centuries before that date. Some English lawyers were still claiming that villeinage existed in law in the 17th century although as a social reality it had by then disappeared. Some historians (*e.g.*, Alexander Eck, George Vernadsky) hold that serfdom did not appear in Russia until the end of the 16th century. Others (*e.g.*, B. D. Grekov) consider that the depression of the free peasantry in Kiev Russia into a servile condition began in the 9th century. In Muslim law there was no intermediate status between slave and free, but in the Seljuk dominions in the Middle East many peasants were economically and socially servile.

Economic and Social Aspects.—It is advisable, therefore, to describe the economic and social aspects of serfdom, without neglecting the legal definitions that were later found necessary to consolidate the privileges of those who benefited from the servility of others. The vast majority of serfs were peasants. This means that they obtained their subsistence from a plot of land. This, rather than their place in public law, was the essential feature differentiating serfs from slaves. The slave was an instrument of production owned by a master who provided him with food and clothing. The serf provided his own food and clothing from his own productive effort. Under fortunate circumstances he could produce more than his own subsistence requirements and accumulate reserves of his own. He was, however, a dependent peasant; this meant that a substantial proportion of the surplus product of his holding was taken by his overlord. Alternatively, or additionally, the lord used the serf's labour for the cultivation of the portion of his land that was not held by tenants (called demesne land). The payment of rent in money, in kind, or in labour was not, however, the only or even the essential sign of the serf's dependence, for rents are paid by free men as well as by serfs. The essential additional mark of serfdom was lack of freedom of movement or

the peasant family, and restrictions on the free disposal of its property. When the peasant could leave his holding, and if necessary his village, without a lord's permission, he was no longer a serf.

Occurrence.—Serfdom was a very ancient and widespread institution. But there has been no simple line of development in history from freedom to serfdom or vice versa. In ancient China there were periods of serfdom and periods of relative peasant freedom, the latter usually coinciding with periods when the central government was strong and the local power of the landlords was weak. In ancient Egypt, too, when the hereditary power of the landowners was great (from the 5th to the 12th dynasties) the peasants were bound to their holdings. Before and after that period, when the ruling dynasties established strong central control, freedom of movement and free alienation of land by the peasantry were permitted. Serfdom in the ancient civilizations of the Mediterranean is less well documented than slavery. It seems clear, however, that in Crete and Sparta during the era of Dorian domination of the indigenous populations, the serfs were bound to the hereditary domains of the aristocracy; they were deprived of freedom of movement and were obliged, in the case of Sparta, to pay half the product of their holdings to their overlords. In Crete in the 5th century serfdom rather than slavery was paramount in the economy. There, serfs had rights, guaranteed in law, that distinguished them from chattel slaves. But not until the late Roman Empire and the Middle Ages in Europe is there sufficient evidence for historians adequately to relate the expansion and decline of serfdom to changing economic and political circumstances.

SERFDOM IN EUROPE

The serfdom of medieval and modern Europe was a complex social institution that changed in form according to a variety of specific circumstances. The ratio of land to labour within any society was a basic factor that could operate in different ways according to political conditions. If abundant land was available for colonization, free conditions of tenure might be offered by some landlords to attract peasant settlers. This could reduce the general level of rents and services. On the other hand, the landlords, in order to combat this tendency, might bind the peasants by legal restrictions to prevent them from leaving their holdings. If there was pressure of population and a great demand by the peasants for landed holdings, then landlords would be in a position to exact onerous returns from tenants. But rents and services might be so heavy that enserfment would be the only guarantee that they would continue to be rendered. Another factor making for enserfment, especially in times of weak central governments, was the development of ties of personal dependence between the rich and strong and the poor and weak. This was the case in dynastic Egypt, in the late Roman Empire, in the barbarian states from the 6th to the 12th centuries (*see* FEUDALISM), and in the Byzantine Empire. The social framework within which these fluctuations of serfdom operated was, of course, one where the principal classes were landowners with established property rights and political power, and peasants occupying dependent holdings. The extent to which the state power acted on behalf of the landowners varied not only with its own strength but also according to the degree to which it represented landowning as against urban, commercial, and industrial interests. Only when the varying interaction of all these factors is examined can the strength of serfdom in any particular period of history be correctly understood.

Origins of Serfdom.—One of the sources of the servile population of medieval Europe was the body of slaves of the late Roman Empire and of the barbarian states that succeeded the Empire. As early as the 2nd century A.D. the slackening of production for the market caused changes in estate management. Large estates that had been worked by slave gangs housed and fed by the estate owner were divided into peasant holdings, some of which were granted to the slaves. It is to these slaves of the Roman period and later who were given their own holdings that we may trace the probable origin of the servile holdings of the Carolingian estates of the 9th century. When they were provided with peasant holdings the slaves were not necessarily freed. There were, however, numerous instances of the freeing of slaves both in the empire and in the barbarian successor states of the Goths, Franks, and Lombards. In some cases these enfranchisements put the former slave on a level with the free members of society, but for the most part the freedman continued to be under the protection of his former master and owed him loyalty and services.

The bulk of the peasants of the late empire and Dark Ages were neither slaves nor freedmen but *coloni*. These *coloni* might have taken up holdings granted by a proprietor, or they might have surrendered their own lands to him in return for protection, receiving back their land as a dependent tenement. This surrender and reissue of land frequently accompanied the act by which a person commended himself to a great man and swore fealty to him, though the act of commendation did not necessarily involve any land transaction. It was made in order to obtain protection (especially in the empire) from the state tax-gatherer and (especially in the disorders of the Dark Ages and early Middle Ages) from invaders and oppressive neighbours. Whatever the origin of the *coloni*, a problem concerning them, which was as old as the Roman Empire, was to prevent them from leaving their land. The solution was to bind them to their holdings. This was done, probably originally for fiscal reasons, by the emperor Constantine in A.D. 332. But it was so useful to the landlords that by the 6th century it was still firmly established, and *coloni*, though legally free, were treated as an inferior element in society.

A substantial proportion of the peasant population in the former territories of the western Roman Empire, in that part of Germany which had formed part of the Carolingian dominions, and in the Byzantine Empire was therefore deprived of freedom of movement, at any rate, in law. This was the case whether they were considered to be attached to the land or whether they were considered to be attached to the person of their lord, as were most dependents of the early Middle Ages. There is evidence of them in the law codes and in the Carolingian estate surveys of the 9th and 10th centuries, but it is uncertain what proportion of the total peasant population they constituted. What this proportion was depends on how much of the total cultivated area was included in the huge estates of the secular and ecclesiastical landlords. This amount cannot be known, though it is certain that in many parts of both the western and Byzantine Empires there was still a substantial survival of small free peasant property. However, on the big estates restrictions on movement were doubtless essential because the rents and services due from the peasant holdings were heavy. Among other things they included labour services on the landlords' demesne land (*see* MANOR). In theory labour services were no more symptoms of servile tenure than other forms of rent or service. But in practice the exaction of labour services required the exercise by the landlord's agents of labour discipline. This was recognized as one of the clearest symptoms of a man's personal subjection. It is not surprising that later on in England the obligation to perform labour services became one of the tests of servile status.

In the 9th and 10th centuries, the serfs in the strict sense of the word, those who in fact were called *servi*, were mainly those descended from the former slave population, though many on the big estates who were not called *servi* (*e.g.*, the *coloni*) had conditions of life that were virtually servile. In the next three centuries economic and political conditions in Europe changed considerably. Population increased, commerce and industry developed, towns grew up, and, both within the old territories of the Carolingian Empire and in sparsely occupied Slavonic lands east of the Elbe, forests and marshes were opened up for cultivation. Politically there was, first of all, a disintegration of the old forms of authority, both central and local, and from the 12th century a reconstitution of feudal monarchies, duchies, and counties. Statistical evidence about serfdom during this period is scanty, but by the 13th century it is clear that there was an immense increase in the number of dependent peasants, whether in the territories of present day France, England, or western Germany. It has been shown that this increase in the numbers of peasants whose social and economic condition was virtually equivalent to servility did not occur, as was once believed, as a result of the spread of the

legal status of the Carolingian *servi* to the *coloni,* freedmen, and other categories of dependent peasants on the big estates.

The *servi* were considered to be personally subjected to one master "to the very bones." Their condition was hereditary, usually through the mother. They had no legal rights in the public courts. They could not normally enter the clerical order. The only way in which their servile status could be ended was by an act of enfranchisement or manumission by their master. Since these serfs constituted a hereditary caste, the only way in which their numbers grew over the centuries was by natural increase. This was offset by manumissions and by escape. By the middle of the 13th century, the serfs in the stricter juridical sense of the word were relatively no more numerous than four centuries earlier. The increase was in the numbers of dependent peasants whose status was socially, if not juridically, servile. This was demonstrated by the fact that they shared with the serfs economic and social disadvantages which brought the two groups so close together that contemporaries as well as historians confused them. The chief disadvantages, which more and more peasants were sharing, were not even specifically of servile origin (in the juridical sense) but resulted from the restrictions of peasant freedom necessary to guarantee the rendering of rents and of labour services on the big estates. The increasing subjection of the English villein in the 12th and 13th centuries is to be understood largely in the context of this type of estate management. But in other parts of western Europe the connection between demesne cultivation and the labour services owed from the peasant holding was disappearing after the 9th century. And yet, as in England, peasant dependency was on the increase. This was because lords at all levels in the feudal hierarchy were strengthening their rights (or seizing rights) of private jurisdiction through the right of command, *bannum*, exercised not merely over their tenants but over all inhabitants within their area of jurisdiction. Even the juridically free tenants had no redress against the lord who had appropriated for himself a jurisdiction that had once been public. In the case of both types of lordship, whether personal or real, or in many instances a mixture of both, there were three principal obligations shared by serfs and by other dependent peasants.

Obligations of Serfs and Dependent Peasants.—The first obligation was the payment to the lord of a head payment or *capitagium* (French: *chevage*). This was common to serfs, to enfranchised men, to those who had commended themselves to a religious overlord, and to other dependent peasants. It was not a heavy payment but it was the sign that the payer accepted his dependence on the lord. Next was the obligation (*forismaritagium*) to obtain the lord's permission for marriage outside the social group or outside the lord's domain. This was particularly important in the case of juridical serfs, for if a male serf married a free woman, the offspring followed the mother's condition. But in the case of both juridical serfs and dependents, marriage outside the domain was (apart from flight) the most serious threat to the lord's future supply of tenants and labourers. The third principal obligation was that of surrendering part of the peasant inheritance to the lord at the death of the servile or subject tenant. This *mainmorte* of the serf was the whole or a substantial part of the inheritance, where there were no direct heirs to succeed. If there were direct heirs the lord would allow the inheritance to them, so that they should continue production and pay rent. Subject peasants who were not juridical serfs had a modified obligation, that of paying the best beast or chattel, but this was paid whether the direct heirs succeeded or not. These were the three most common symbols of dependence; other symbols included the payment of an arbitrary tallage, a seigneurial tax, which, while not specifically a mark of juridical servility, was a burden shared by juridical serfs and subject peasants alike.

This necessarily simplified description of serfdom and peasant dependence between the 9th and 13th centuries must be modified in a number of respects. From region to region there were varying degrees of dependence and of servile obligations. The German *hörigen,* descendants of demesne slaves, and other grades of dependents merged into a general class of *leibeigene* (bondmen) by the 13th century. The evolution is not fundamentally different in western Germany from that of the other parts of the former Carolingian Empire, except for the *ministeriales* or *Dienstmänner.* These were serfs who were originally employed by lords in military and administrative duties and were closely associated with the lord and his household. Their military role became emphasized, they were endowed with fiefs, and by the 13th century they were on their way into the nobility, in spite of such relics of servile status as restrictions on freedom of marriage and alienation of property. In England serfdom was much more related to the holding of land than to personal dependence on a lord. This was partly due to the fact that private jurisdiction and the private right of the *bannum* were there undeveloped, owing to the strength of the central government. It was also due to the maintenance of the close tie between demesne and peasant tenements on the big estates. Hence, 13th-century English lawyers, acting in the interests of estate owners, sometimes attempted to lay down that the performance of labour service was a criterion of unfree condition. This equation of unfreedom with the performance of labour services is also found in Bavaria and is obviously a local reaction to specific economic needs. It was to become important again in eastern Europe.

Factors Affecting the Extent of Serfdom.—Another important modification to the picture of serfdom arises from the fact that all over Europe factors tending to decrease serfdom existed contemporaneously with those that strengthened it. Most important of these was the attempt by landlords and political authorities to encourage the colonization of waste and forest land. Hence significant groups of free tenants who paid money rent established themselves in newly colonized areas. In England and France free peasant tenures were created in considerable numbers in the 12th century, especially in areas where virgin forest survived. Abbot Suger of St. Denis in the early part of the century took the initiative in inviting peasant *hospites* (*hôtes*) to settle on abandoned or uncultivated sites, on free conditions of tenure. At the end of the century the bishop of Worcester, also in a heavily wooded region, was granting holdings that had formerly been woodland to cultivators for a money rent with hereditary right. In Spain, particularly in Castile, there were other reasons for an expansion of free peasant tenures during this same period. It was again a call for colonizers, this time of land won in the reconquest from the retreating Moors by the Christian kingdoms of the north. But the most spectacular shift of the balance between peasant serfdom and freedom occurred in the newly colonized lands of eastern Germany and in the neighbouring Slav and Magyar states. The vast move of Flemings and Germans east of the Elbe is well known. The new villages they settled, often in former Slav territory, under the so-called "German Law" were essentially settlements of free men, for freedom was the bait. The Slavs themselves were promoting the same sort of free peasant settlements, numbering many hundreds before the middle of the 14th century in Greater and Lesser Poland, not to mention over a thousand in Silesia where the German element was also present.

Partly in order to offset the lure of freedom in new areas of colonization, partly in order to raise cash, landlords in the old settled districts of western Europe tipped the balance against peasant subjection still further. In France many charters were issued, particularly in the mid-13th century, to whole communities. These exempted their inhabitants from burdens such as *mainmorte*, *formariage*, and *chevage*, sometimes, but by no means always, including juridical serfs in the act of emancipation. In addition the French crown, for purely fiscal reasons, adopted a policy of individual manumission of its serfs particularly on crown lands east of Paris. This was systematized in the 1290s and *c.* 1310–20. The reasons given for emancipation are of some interest. They express one of a number of common medieval doctrines about serfdom, widespread in time and place . . . "As according to the law of nature everyone should be born free, but by certain usages and customs of great age preserved in our kingdom . . . and also perhaps because of the misdeeds of their predecessors, many persons of our common people have fallen into the bonds of servitude and into various conditions, which much displeases us, considering that our kingdom is called the Kingdom of the Franks . . . we have ordered . . . that these servitudes shall be brought to freedom and

to those who by birth or long standing or recently through marriage or residence have fallen into servile condition, or could so fall, freedom shall be given on good and convenient terms . . ." (Preamble to Letters of Commission of July 3, 1315 and Jan. 23, 1318, quoted in M. Bloch, *Rois et Serfs*, 1920). Evidently the attitude of those social classes of medieval society who profited from serfdom must have been at all times ambivalent. In Italy there was a similar movement for enfranchisement at the same period. The initiative came from the urban communes which were among the most powerful rulers of the peninsula. Their motives were more mixed than those of the French crown and included the wish to weaken the power of the landowning nobility; to increase the number of free taxpayers to the commune; and to increase the urban labour force. These real motives were also covered by moralizing. The enfranchisement of serfs by Bologna in 1256–57 was attributed to the realization that slavery was the consequence of the fall of man, that man's natural condition is freedom, and that Bologna was the home of freedom.

By the 14th century economic conditions in western Europe were favourable to the replacement of the servile by the free peasant tenant. The growth of the power of central and regional governments permitted the enforcement of peasant-landlord contracts (as in *métayage* or stock and land lease contracts) without the need for peasant servility. The final abandonment of labour services on demesnes removed the need for the direct exercise of labour discipline. The drastic population decline after 1350, as a result of the Black Death, altered the land-to-labour ratio in favour of tenants. And, not least, peasant risings which were endemic in England, France, Italy, and Spain in the 14th and 15th centuries, culminating in the German Peasant War of the early 16th century, also forced more favourable terms of peasant tenure. Peasant demands in some of these risings illustrate vividly both the character of serfdom at the time and the new conditions envisaged by the rebels. Local rebellions in England, frequent from the middle of the 13th century, were directed against servile status mainly because those of such status had no legal redress against increases in rents and services. By the time of the Peasants' Revolt of 1381 the rebels still aimed at free status and low rents, and among other things, free access to the commons and a free market in land. In 12th and 13th-century Italy peasant rebellions were partly, at any rate, the cause of grants of charters of liberties which included the fixing of rents and services and safeguards against imprisonment without legal process. The peasant risings in Catalonia in the late 15th century were against those personal obligations which had replaced land rent as the main burden on the peasant. Between 1493 and 1525 the west German peasant movement had, of course, many political and religious objectives. But here again demands for the abolition of serfdom were linked with requests for the reduction of rents and services and the restoration of access to the commons. Such late references to western serfdom can, however, be misleading. Whatever legal rights landlords might have over their tenants, or over peasants within their sphere of jurisdiction, for practical purposes most peasants had freedom of movement and terms of tenure that were contractual rather than customary. They were not necessarily better off economically than their servile forebears, but their status in society conformed to their economic position rather than to the legal classification of their holdings or their persons.

Modern Serfdom in Eastern Europe

This favourable evolution was not shared by the peasants of eastern Europe. In the later Middle Ages peasant status from eastern Germany to Muscovy deteriorated sharply; a second serfdom began which was prolonged well into modern times, in Russia until 1861. Peasant conditions in eastern European countries before the 14th century do not seem to have been worse than those of the west. In some ways they were better, for in eastern Germany, Poland, Bohemia, Moravia, and Hungary the colonization of forest land had led to the establishment of many free peasant communities. But a combination of political and economic circumstances reversed these developments.

Eastern Europe from the Baltic to the Balkans in the 14th and 15th centuries suffered wars even more devastating than those of western Europe. These not only diminished the peasant population, and increased the area of uncultivated land, as in the west, but also increased the power of the nobility at the expense of central governments. In eastern Germany, Prussia, and Poland this coincided with an increased demand for grain from western Europe. To profit from this demand landlords took back peasant holdings, expanded their own cultivation, and made heavy demands for peasant labour services. These were increased to as much as four days a week from the peasant holding in 15th-century Poland. This increase in services eventually led to pressure by landlord interests for means of legally binding the peasant to his holding. This was beginning in Prussia as early as 1412 and was achieved in Poland by legislation of the Diet early in the 16th century. In Bohemia, Moravia, and Hungary, the same background of devastation by dynastic, religious, and national wars created similar results. Despite the temporary upsurge of the peasantry of Bohemia during the Hussite Wars, the power of the nobility was restored by the end of the 15th century and legislation in 1497 and 1500 tied the peasants to their holdings. In Hungary, which was at war with the Turks, the same enserfment of the peasantry was achieved early in the 16th century. Not until the end of the 18th century were the peasants of the Austro-Hungarian Empire freed from a serfdom that was defined by the Emperor Joseph II himself as the absence of freedom of movement, of freedom of marriage, and of the right to learn a profession according to one's choice.

The intensification of serfdom in Russia was comparable with that of the other eastern European countries. To say that serfdom in Russia did not begin until the 16th century is to take too legalistic a view. As early at least as the 12th century there were in addition to slaves more and more peasants who, through indebtedness, were becoming dependents of their landlords. Even some of the free peasants were being drawn into dependent association with the landowner's household. But the opportunities that the vast uncultivated wastes and forests presented to peasants who were discontented with their conditions undoubtedly kept a considerable element of freedom in Russian peasant status. The expansion of the state of Muscovy in the 15th and 16th centuries led, however, to an increase in state taxation at the same time as landlords were demanding heavy rents and labour services under the stimulus of an increasing internal grain trade. This caused peasant discontent which expressed itself in flight. The government, therefore, in the interests of the new class of military fief-holders on whom it depended for its armed force, at various times between 1450 and 1550, first of all prevented peasants from leaving their holdings other than in the period near St. George's day (Nov. 26, in the East). At the end of the 16th century the privilege of moving on St. George's day was abolished, at first temporarily, though fully servile conditions were embodied in the code of 1649. Peasant conditions continued to deteriorate in the later 17th and 18th centuries, the requirements of the landlords for heavy rents and labour services and for proprietary rights in the serf analogous to slavery being fully supported by the state. (For the emancipation of the serfs under Alexander II *see* Russian History.)

SERGE, a fabric, much used for military uniforms, made in an even-sided twill weave (*see* Weaving) and usually clear finished—that is, the fibre ends on the surface of the cloth are sheared or singed so that the twill weave is very prominent, producing a flat diagonal rib pattern that goes from the lower left to the upper right selvage on the right side. Serge was originally made of wool, but is now sometimes made of other fibres, or of wool blended with other fibres, in weights ranging from 5 to 31 oz. per sq. yd.

SERGEANT, JOHN (1622–1710), English Roman Catholic controversialist, especially well known for his criticism of Locke, was born in 1622 at Barrow-upon-Humber, Eng. He was educated privately and at St. John's College, Cambridge, and then became secretary to Thomas Morton, bishop of Durham. The result of his researches into early church history was his conversion to Roman Catholicism. After a period of theological study at the English College at Lisbon, he was ordained and was sent on the English mission in 1652 to defend the Catholic cause. In 1675 he was in France, where he lived for a time with Bossuet. Most of his life was spent in animated theological and philosophical controversy, for which he had an outstanding, if unrestrained, talent. Hardly any Anglican writer of note escaped his argumentative pen, Bishop Stillingfleet, Jeremy Taylor, and Bishop Tillotson being among his more celebrated adversaries. Sergeant was also one of the many critics of Locke, whom he attacked in his *Solid Philosophy Asserted Against the Fancies of the Ideists* (1697). In all he published 34 works, most of which were pamphlets. He was said to have died "with a pen in his hand."

Sergeant holds that we can extend and explain our knowledge of the world by the application of metaphysical principles and of the general principles of reason or "maxims," and that where empirical investigations themselves yield no new knowledge, we must resort to these principles. He therefore criticized Locke, who denied the importance of these principles in extending our knowledge, though he did not rule them out entirely. *See* Locke, John.

See for Sergeant's criticism of Locke, J. W. Yolton, *John Locke and the Way of Ideas* (1956).

SERGEANT AT ARMS. In early usage in England a sergeant at arms was generally an armed officer of a lord, often one of a special body required to be in immediate attendance on the king's person, to arrest traitors and other offenders. Thus the title now denotes certain court, parliamentary, and city officials with ceremonial (and ostensibly disciplinary) functions. It is perhaps most readily associated in modern times with an officer in each house of the British Parliament (where the word "sergeant" is spelled with a "j"), paralleled by two officers in the United States Congress. In the British House of Commons, the serjeant at arms is appointed by the sovereign, but thereupon becomes the servant of the House. His duties include attendance on the speaker, with the mace, and maintenance of order in the House and its precincts. In the House of Lords, though similarly appointed by the crown, he remains the officer of the lord chancellor (whom he attends with the mace) rather than of the House. The sergeants at arms in the United States Congress, on the other hand, are elected by the members of Congress. The sergeant at arms of the House of Representatives has similar duties with the mace and also exercises certain police functions about the legislative buildings. (E. C. Tn.)

SERGIPE (originally Sergipe d'el Rey), a state in northeastern Brazil bounded east by the Atlantic, south and west by the state of Bahia, and north by Alagôas, from which it is separated by the São Francisco River. It is the smallest of Brazilian states, with an area of 8,492 sq.mi. Its population (1960) 760,273, is about three-fourths of mixed racial origin and Negroes. The northern part of the state slopes downward to the São Francisco River, while the southern part drains into the Atlantic. Sergipe is traversed by a number of small rivers which are frequently dry in their upper reaches. The largest of these are the Vasa Barris, the Real, and the Cotinguiba, which are not navigable to ocean shipping. From east to west the state is divided into two major geographic regions, with a narrow, heavily forested coastal strip giving way to a higher zone of rough open country. The interior is devoted primarily to livestock raising. The lower, fertile lands are cultivated and produce sugar, coconuts, cotton, maize, tobacco, rice, beans, and cassava. Sergipe is Brazil's leading producer of coconuts, although sugar is its principal money crop. The only manufacturing industries of importance are cotton mills, sugar factories, and distilleries. One of the largest sugar *usinas* in Brazil is located at Riachuelo near Laranjeiras. However, a considerable expansion of vegetable and mineral processing industries is anticipated, since Sergipe has a surplus of electric power available from the Paulo Afonso hydroelectric project.

The capital of the state is Aracajú (*q.v.*), on the estuary of the Cotinguiba River, near the coast. It is connected by rail with the town of Propriá on the São Francisco River and with Bahia to the south. Highways link Aracajú with interior towns in Sergipe and with Bahia and southern Brazil. Domestic airlines provide regular service between Aracajú and all major Brazilian cities. Other important towns in Sergipe are Estância, Laranjeiras, Capela, São Cristóvão, formerly the capital, and Lagarto. Sergipe was settled in the 16th century by cattlemen and sugar planters from Bahia and it remained an administrative district of Bahia until 1821, when it became an independent captaincy. During the period of the Dutch conquest (1624–54) Sergipe was a focal point of the Brazilian resistance. It became a province of the empire in 1824 and a state in the republic in 1889. (R. E. P.)

SERGIUS, SAINT, of Radonezh (in Russian Sergii Radonezhski; baptismal name Varfolomei Kirillovich) (*c.* 1315–1392), Russian spiritual leader to whom the monastery of Troitse-Sergiyevo owed its lasting fame as a centre of the religious and social life of the nation. He was born in the city of Rostov, probably in 1315, of noble parents who soon after became impoverished and moved to the village of Radonezh, north of Moscow. At this time Tatar political oppression and social, economic, and moral decline within Russian society made "worldly" life tedious and distressing for high-minded men; therefore, after his parents' death the young Varfolomei Kirillovich withdrew into a wild forest and for several years lived as a hermit in a log cabin. Taking monastic vows in 1337, with the name Sergius, he became the abbot of the new monastery at Troitse (named Sergiyevo after him, but renamed Zagorsk in 1930).

Even when Sergius had won fame for his sanctity, he remained the poorest, humblest, and most hard-working member of the community and firmly refused the metropolitan Alexis' invitation to be his successor. In the second half of the 14th century great numbers of Russians, princes and poor peasants alike, began to make pilgrimages to the monastery. In 1380 the grand prince Dimitri (Donskoi), when he was preparing his fateful struggle against the Tatars, turned for advice and blessing to Sergius, whose message helped to inspire the Russian warriors before their victory at Kulikovo. Sergius died in 1392, revered throughout Russia. His feast day is Sept. 25.

See N. Zernov, *St. Sergius, Builder of Russia* (1939). (S. G. Pu.)

SERGIUS, the name of four popes.

Saint Sergius I, pope from 687 to 701, came of an Antiochene family which had settled at Palermo. He was elected successor to Conon after a fierce struggle between two other candidates, Paschal and Theodore, and was consecrated on Dec. 15, 687. In 689 he baptized King Ceadwalla of Wessex in Rome. For rejecting certain canons of the Trullan council of 692, Justinian II commanded his arrest and transportation to Constantinople, but the militia of Ravenna and the Roman citizenry forced the imperial officer to abandon the attempt. Sergius died *c.* Sept. 8, 701. His feast day is Sept. 8.

Sergius II, pope from 844 to 847, a Roman of noble birth, elected by the clergy and people to succeed Gregory IV in January 844, was forthwith consecrated without waiting for the sanction of the emperor Lothair I. Lothair accordingly sent his son Louis (later Louis II) with an army to punish the breach of the Roman constitution of 824, which had affirmed the emperor's sovereignty over the pope. A pacific arrangement was ultimately made, and

Louis was crowned king of the Lombards by Sergius. In this pontificate Rome was ravaged and the churches of St. Peter and St. Paul robbed by Saracens (August 846). He died Jan. 27, 847.

SERGIUS III, elected pope by one of the factions in Rome in 898, simultaneously with John IX, was expelled from the city by his adversaries. He reappeared early in 904, seized the two claimants, Leo V and Christopher, who were disputing the succession of Benedict IV, and had them strangled, being himself consecrated on Jan. 29. His adherents rallied round the master of the wardrobe Theophylact and his wife Theodora. Sergius is reputed to have been the lover of Theodora's daughter Marozia and the father of her son, the future Pope John XI. Sergius was very hostile to the memory of Pope Formosus and refused to recognize any of the ordinations celebrated by him, thus causing grave disorders. He also affected to consider as antipopes not only John IX but also Benedict IV and Leo V as well as Christopher. He restored the Lateran basilica, which had fallen down in 897. He died in the second quarter of the year 911.

SERGIUS IV, pope from 1009 to 1012, had been known as "Pigmouth" before he was consecrated successor to John XVIII in July 1009. He was powerless in the hands of John II Crescentius (*see* CRESCENTII) and the Roman nobles. He died in May 1012.

See also PAPACY.

SERGIUS (IVAN NIKOLAEVICH STRAGORODSKI) (1867–1944), patriarch of Moscow and all Russia, who achieved the recognition of the Russian Orthodox Church by the Soviet government after the Revolution. Born on Jan. 11, 1867 (old style), in Arzamas near Nizhni Novgorod (now Gorki), he came of a family with a tradition of entering the priesthood and attended the St. Petersburg academy. After a holiday in the famous monastery on Valaam Island, in Lake Ladoga, where he felt an inner call to the monastic life, he took his vows on Jan. 30, 1890 (O.S.), and chose Sergius as his name in religion. After a brilliant final examination he alternated between missionary and scholarly activity. He was a member of the Orthodox Japanese Mission (1890–93 and 1897–99), assistant inspector at the Moscow Theological Academy (1893), priest to the embassy church in Athens (1893), lecturer in theology (1896), rector of the priestly seminary in St. Petersburg and assistant inspector of the theological academy there (1899), and then rector of the same academy (1901). In the same year he was consecrated titular bishop of Yamburg. These years were filled with intensive theological work for lectures and publications, his special subject being dogmatic differences with the Western confessions. In 1905 Sergius became archbishop of Finland and Viborg and until 1907 he devoted all his strength to the erection of a bulwark there against Scandinavian Protestantism. Sergius played a large part in the calling of the regional synod of 1917 and the restoration of the patriarchate, himself becoming metropolitan of Nizhni Novgorod.

After the death of the patriarch Tikhon (*q.v.*) in 1925 Sergius soon became locum tenens of the patriarchal see. After some months' imprisonment in 1927 he sent out two epistles which called upon the faithful to refrain from anti-Soviet activity and to recognize the Soviet government as permitted by God. At the same time he achieved by negotiation with the government, in return for a declaration of loyalty, the recognition of the Russian Orthodox Church, its faith, its canonical organization and leadership, as compatible with the Soviet order, and also won the registration of the whole church as a religious association, which had hitherto been refused. Although difficult years still lay ahead of the Russian Church, Sergius thereby gave it a legal basis for its defense against the revivalist "Living Church" Movement, which had severely endangered its faith and unity, being at first supported by the Soviet government. During World War II, at the time of the German invasion, Sergius, who had again been arrested during Stalin's 1937 purge, at once called upon the faithful to defend their country and resist the enemy; he proved the church's patriotism, which had up to then been continually called in question by the Soviet government, by monetary and other collections, and by fitting out the famous tank division, "Dimitri Donskoi." On Sept. 4, 1943, he reaped the first fruits of long and patient work. Stalin received representatives of the Russian Orthodox Church and gave them permission to choose a patriarch once more. On Sept. 8 Sergius was elected to the position by a simplified procedure, but died on May 15, 1944, in Moscow. During the last months of his activity the church benefited by the ending of internal divisions and by contact with other Orthodox bodies and with the Anglican Church.

See J. Shelton-Curtiss, *The Russian Church and the Soviet State* (1953). (F. v. L.)

SERGIUS AND BACCHUS, SAINTS, two 4th-century martyrs, according to legend, officers of the Roman Army on the Syrian frontier. On their refusal to sacrifice to Jupiter, they were sent to Rosafa in Mesopotamia, where they were scourged so severely that Bacchus died. Sergius later was beheaded. The church over Sergius' grave was restored in 431, and shortly afterward Rosafa became the seat of a bishopric; it was renamed Sergiopolis. Sergius and Bacchus became protectors of the Byzantine Army. Their feast day is Oct. 7.

See H. Thurston and D. Attwater (eds.), *Butler's Lives of the Saints*, vol. iv, p. 50 (1956).

SERI, a tribe of Mexican Indians on Tiburón Island in the Gulf of California; numbering about 300–400 in the 1960s, some of them lived on the mainland in Sonora State (*see* SONORA), working for the most part as farm labourers. Many of their ancient ways of life continued on Tiburón. Traditionally nonagricultural, they lived by gathering, hunting, or fishing for such edibles as shellfish, turtles, pelicans, and cactus fruit. Their crude, weakly constructed dwellings of twigs and cacti, simple cane spears, hunting bows, and pebble tools earned them a reputation as being among the most primitive aboriginal groups of North America. However, they did produce serviceable pottery and fashioned boat-shaped rush rafts on which they successfully navigated to the mainland. Without chiefs, and lacking a real political structure, the matrilocal Seri practised polygamy and tree burial (replaced by inhumation in more recent years). Linguistically, they are classified among the Hokan speakers (*see* HOKAN).

Davis and E. Y. Dawson, "The Savage Seris of Sonora," *Scientific Monthly*, vol. 60 (1945); W. B. Griffen, *Notes on Seri Indian Culture* (1959); B. Malkin, *Seri Ethnozoology* (1962); W. H. Lindig, "Tree Burial Among the Seri Indians," *Ethnology*, vol. 3 (July 1964).

SERIEMA (CARIAMA), a South American bird belonging to the family Cariamidae, allied to the cranes (*q.v.*) and trumpeters. There are two species, both restricted to the southern half of South America. The crested seriema (*Cariama cristata*), with long legs and neck, stands about two feet high. The beak and legs are red, the plumage brownish above and dull white beneath with bluish skin around the eyes. It inhabits the grasslands, where it runs swiftly. The nest is built in bushes or trees and contains two buff eggs blotched with red-brown. The young are hatched, after about 25 days' incubation, covered with gray down. The seriema feeds on insects, snails, reptiles, and berries.

Burmeister's, or the gray, seriema (*Chunga burmeisteri*), which inhabits wooded areas, is darker and grayer, with a shorter crest and shorter legs.

SERIES, in mathematics, is the indicated sum of a set of terms. The notion of a series has close connection with that of a sequence. (*See* NUMBER SEQUENCES.) The simplest example of a sequence is that of positive integers $1, 2, 3, \ldots, n, \ldots$; this particular example is important for the general definition. An infinite sequence of numbers exists if every positive integer $1, 2, 3, \ldots, n, \ldots$ is assigned a number; in what follows the expression "sequence" stands for "an infinite sequence of numbers." Some examples of sequences are as follows:

$$1^2, 2^2, 3^2, \ldots, n^2, \ldots \tag{1}$$

$$1, 0, 1, 0, 1, \ldots \tag{2}$$

$$1, -2, 3, -4, 5, -6, \ldots \tag{3}$$

$$1, \tfrac{1}{2}, \tfrac{1}{3}, \ldots, \frac{1}{n}, \ldots \tag{4}$$

The numbers constituting a sequence are called the terms of the sequence (such as the first, the second, . . . , the nth, . . .). It is customary to denote a sequence by a single letter with a

subscript (index) indicating the position of the term in the sequence; for example, $a_1, a_2, a_3, \ldots, a_n, \ldots$, or $b_1, b_2, b_3, \ldots, b_n, \ldots$. The abbreviated notation $\{a_n\}$ for $a_1, a_2, a_3, \ldots, a_n, \ldots$ and similarly with other letters also is used. It will be assumed that the terms of a sequence are real numbers (*see* NUMBER: *The Real Number System*); the case of sequences of complex numbers is considered below.

If the terms of a sequence $\{a_n\}$ have the property that $a_n \leq a_{n+1}$ for each n, the sequence is said to be increasing (or, sometimes, nondecreasing); if $a_n < a_{n+1}$ for each n, the sequence is strictly increasing. If $a_n \geq a_{n+1}$ for each n, the sequence is decreasing (or nonincreasing); if $a_n > a_{n+1}$, it is strictly decreasing. Sequences that are either increasing or decreasing are called monotone (monotonically increasing or monotonically decreasing, as the case may be). Sequences (1) and (4) above are monotone, while (2) and (3) are not. If all the terms of the sequence $\{a_n\}$ are less than a given number M (in symbols, $a_n < M$ for some M and all n) the sequence is said to be bounded above. If all a_n exceed a certain number, $\{a_n\}$ is said to be bounded below. Sequences bounded both above and below are simply called bounded. For example, sequence (1) is bounded below but not above, (2) is bounded, and (3) is not bounded either above or below.

A sequence $\{a_n\}$ is said to converge (or tend) to the limit a if the terms a_n approach a indefinitely as n increases; in symbols

$$\lim_{n\to\infty} a_n = a \text{ or, } a_n \to a$$

A precise definition is as follows: a_n tends to the limit a if given any positive number ϵ (no matter how small) we have $|a_n - a| < \epsilon$ for all n large enough. If $\{a_n\}$ tends to a limit, the sequence is said to be convergent; otherwise it is divergent. The following type of divergence is important: $\{a_n\}$ is said to diverge to $+\infty$ or, in symbols

$$\lim_{n\to\infty} a_n = +\infty \text{ or, } a_n \to +\infty$$

if for any number M (no matter how large) a_n is greater than M for all n large enough; divergence of a sequence to $-\infty$ is defined correspondingly. Of the sequences mentioned above, (4) converges to the limit 0; (1) and (2) diverge (the former to $+\infty$). Whether a given sequence converges and, if so, toward what limit, is not always easy to decide. The following facts can be helpful here.

I. If $a_n \to a$ and $b_n \to b$, then

$$a_n + b_n \to a + b,\ a_n b_n \to ab,\ a_n/b_n \to a/b$$

the last relation requiring, however, the additional assumption that $b \neq 0$.

II. Every convergent sequence is necessarily bounded; example (2) shows that the converse is not true: a bounded sequence need not converge.

III. If a sequence is increasing and bounded above, or decreasing and bounded below, it converges.

IV. If a sequence converges, then its terms, coming arbitrarily close to the limit, must also come arbitrarily close to each other, provided the indices are large enough. The converse of this is also true, though less easy to prove, and the result is the following important theorem of Cauchy: a sequence $\{a_n\}$ converges if and only if it has the following property: for any positive number ϵ (no matter how small) $|a_m - a_n| < \epsilon$ for all m and n large enough.

Starting with a sequence $a_1, a_2, \ldots, a_n, \ldots$ a new sequence $s_1, s_2, \ldots, s_n, \ldots$ is formed by the following rule:

$$s_1 = a_1,\ s_2 = a_1 + a_2,\ s_3 = a_1 + a_2 + a_3, \ldots$$
$$s_n = a_1 + a_2 + \ldots + a_n, \ldots$$

If $\{s_n\}$ converges to limit s, then it is said that the infinite series

$$a_1 + a_2 + a_3 + \ldots + a_n + \ldots$$

converges to sum s. Instead of $a_1 + a_2 + \ldots + a_n + \ldots$ it is customary to write $\sum_{n=1}^{\infty} a_n$ or, simply, Σa_n; the Greek letter sigma is a symbol for summation. The numbers s_n are called the partial sums of the series Σa_n, and the relation $s_n \to s$ is also written $\Sigma a_n = s$. The numbers a_n are the terms of the series Σa_n.

Given any sequence $b_1, b_2, \ldots, b_n, \ldots$, there is always a series

$$b_1 + (b_2 - b_1) + (b_3 - b_2) + \ldots + (b_n - b_{n-1}) + \ldots$$

whose partial sums are $b_1, b_2, b_3, \ldots, b_n, \ldots$. Hence, every series is represented by a sequence (that of its partial sums) and, conversely, every sequence by a series. It follows that every statement about series can be given in a form bearing on sequences, and conversely (but usually, in individual cases, one form may be preferable to the other). For example, Cauchy's theorem stated above and pertaining to sequences assumes, in the case of series, the following form:

V. A series Σa_n converges if, and only if, given any positive number ϵ, $|a_{m+1} + a_{m+2} + \ldots + a_n| < \epsilon$ for all m large enough and any n greater than m. In particular (taking $n = m + 1$), the terms of a convergent series must necessarily tend to 0.

Examples.—If a is any number and q is any number of absolute value less than 1, the series $a + aq + aq^2 + \ldots + aq^{n-1} + \ldots = \Sigma aq^{n-1}$ (called a geometric series) converges, and its sum is $a/(1 - q)$.

The series $\Sigma 1/n = 1 + \frac{1}{2} + \frac{1}{3} + \ldots$, called the harmonic series, diverges.

If the terms of a series are positive numbers, the series is called positive. The partial sums of a positive series form a strictly increasing sequence and, in view of proposition III, a positive series converges if its partial sums are bounded above. If the partial sums of a positive series are not bounded above, the series diverges to $+\infty$. Proposition III also shows that:

VI. If Σa_n and Σb_n are positive series, and if $a_n \geq b_n$ for all n, then the convergence of Σa_n implies convergence of Σb_n and, equivalently, the divergence of Σb_n implies that of Σa_n. This result, usually called the comparison test, is very useful since the knowledge of convergence or divergence of some positive series can be utilized to obtain information about other series. For example, from the fact that the geometric series Σaq^{n-1} converges if a is positive and q is positive and less than 1, it is possible to deduce the following corollaries for positive series:

VII. Suppose that $a_{n+1}/a_n \to l$. Then, if $l < 1$ the series Σa_n converges; if $l > 1$ the series diverges (ratio test).

VIII. Suppose that $\sqrt[n]{a_n} \to l$. If $l < 1$, the series Σa_n converges; if $l > 1$, the series diverges (root test).

If the limit l in VII or VIII exists but is equal to 1, the test fails (the case $l = 1$ can occur for both convergent and divergent series) and one must look for other tests. There are many of them but the most useful is the following one based on the notion of the integral:

IX. If $f(x)$ is a function defined for x positive, itself positive and steadily decreasing to 0 as x increases indefinitely, then the series $\Sigma f(n) = f(1) + f(2) + f(3) + \ldots$ converges or diverges according as the integral $\int_1^{\infty} f(x)dx$ is finite or not (the integral test).

When applied to the function $f(x) = x^{-k}$, where k is a fixed positive constant, the test shows that the series

$$1^{-k} + 2^{-k} + 3^{-k} + \ldots + n^{-k} + \ldots = \sum_{n=1}^{\infty} n^{-k}$$

converges if $k > 1$ and diverges in all other cases. The result is not deducible from either the ratio or root test, since for the series $\sum_{n=1}^{\infty} n^{-k}$, l is equal to 1 both in VII and VIII.

Of interest among series that are not positive are alternating series; this name is given to series $a_1 - a_2 + a_3 - a_4 + \ldots$ where the numbers a_n themselves are of constant sign. It can be shown that such a series converges if $\{a_n\}$ decreases monotonically to 0. For example, the series $1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \ldots$ converges.

A series Σa_n is said to converge absolutely if $\Sigma |a_n|$ converges. Cauchy's theorem for series shows that if a series converges absolutely, then it converges in the ordinary sense; but the example of the convergent alternating series $1 - \frac{1}{2} + \frac{1}{3} - \ldots$ shows that a series may converge without converging absolutely. It follows

that absolutely convergent series form a special class among all convergent series. Since series $\Sigma|a_k|$ have positive or zero terms, the problem of whether a given series converges absolutely can be solved by applying one of the tests for the convergence of positive series. In many cases the simplest way of proving that a certain series converges is by showing that the series converges absolutely, and this shows the importance of positive series for the general theory of series. Absolutely convergent series have many properties that are not shared by all convergent series. The most important of them is the fact that if a series converges absolutely, then arbitrary changes in the order of the terms of the series affect neither the convergence nor the sum of the series. The situation is completely different for series that converge but do not do so absolutely (such series are called conditionally convergent); by a suitable change of the order of the terms such a series can be made to converge to any prescribed sum, or can even be made divergent (theorem of Riemann). Hence, unlike the case of absolutely convergent series, a conditionally convergent series has no intrinsic sum and everything depends on the order of the terms.

The number of important series that occurs in mathematics is enormous. A few basic convergent series are listed below:

$$1-\frac{1}{2}+\frac{1}{3}-\frac{1}{4}+\frac{1}{5}-\ldots=\ln 2$$

$$1-\frac{1}{3}+\frac{1}{5}-\frac{1}{7}+\frac{1}{9}-\ldots=\frac{1}{4}\pi \text{ (Leibniz' series)}$$

$$1+\frac{1}{2^2}+\frac{1}{3^2}+\frac{1}{4^2}+\frac{1}{5^2}+\ldots=\frac{1}{6}\pi^2$$

$$1+\frac{1}{3^2}+\frac{1}{5^2}+\frac{1}{7^2}+\frac{1}{9^2}+\ldots=\frac{1}{8}\pi^2$$

$$1+\frac{1}{1}+\frac{1}{1\times 2}+\frac{1}{1\times 2\times 3}+\frac{1}{1\times 2\times 3\times 4}+\ldots=e=2.7182818\ldots$$

Series With Complex Terms.—The convergence of complex sequences and series (*i.e.*, sequences and series whose terms are complex numbers) is formally defined exactly in the same way as in the case of real numbers, the absolute value $|z|$ of a complex number $z = x + iy$ (where i is $\sqrt{-1}$) being $\sqrt{(x^2+y^2)}$. This definition leads to the following important conclusion: if $c_n = a_n + ib_n$, the convergence of Σc_n is equivalent to the simultaneous convergence of Σa_n and Σb_n; and if $\Sigma a_n = s$, $\Sigma b_n = t$, then $\Sigma c_n = s + it$. Hence, the study of complex series reduces to that of real series. As in the case of real series, the absolute convergence of Σc_n is defined as the convergence of $\Sigma|c_n| = \Sigma\sqrt{(a_n^2+b_n^2)}$. Since the convergence of $\Sigma\sqrt{(a_n^2+b_n^2)}$ means the same thing as the simultaneous convergence of $\Sigma|a_n|$ and $\Sigma|b_n|$, the absolute convergence of $\Sigma(a_n+ib_n)$ is equivalent to the absolute convergence of both $\Sigma|a_n|$ and $\Sigma|b_n|$; it therefore implies the ordinary convergence of Σa_n and Σb_n, and so also of $\Sigma(a_n+ib_n)$. Among complex series, absolutely convergent series play the same important role as among real series; in particular, the convergence and the sum of an absolutely convergent complex series are independent of the order of the terms.

Double Sequences and Series.—A double sequence is defined by assigning to every pair m,n of positive integers a number $\{s_{m,n}\}$. A double sequence can thus be written as a double array of numbers:

$$\begin{array}{l} s_{1,1},\ s_{1,2},\ \ldots,\ s_{1,n},\ \ldots \\ s_{2,1},\ s_{2,2},\ \ldots,\ s_{2,n},\ \ldots \\ \ldots\ \ldots\ \ldots\ \ldots\ \ldots \\ s_{m,1},\ s_{m,2},\ \ldots,\ s_{m,n},\ \ldots \\ \ldots\ \ldots\ \ldots\ \ldots\ \ldots \end{array}$$

The indices m,n of a term can be interpreted as the coordinates of a point in a plane. The notion of convergence of a double sequence is not so immediate and can be introduced in many ways (which are not equivalent). The following definition is most commonly used: $\{s_{m,n}\}$ is said to converge to limit l if for any positive ϵ we have $|s_{m,n} - l| < \epsilon$ provided both m and n are large enough. With this definition, changing the terms in any finite number of rows and columns in the table above (the number of changes may be infinite) does not affect the convergence or limit of $\{s_{m,n}\}$.

The definition of convergence of a double series

$$\begin{array}{l} a_{1,1}+a_{1,2}+\ldots+a_{1,n}+\ldots \\ a_{2,1}+a_{2,2}+\ldots+a_{2,n}+\ldots \\ \ldots\ \ldots\ \ldots\ \ldots\ \ldots \\ a_{m,1}+a_{m,2}+\ldots+a_{m,n}+\ldots \\ \ldots\ \ldots\ \ldots\ \ldots\ \ldots \end{array}$$

can also be introduced in various ways; the series itself will be written as $\sum_{m=1}^{\infty}\sum_{n=1}^{\infty}a_{m,n}$ or simply $\Sigma\Sigma a_{m,n}$. Three definitions follow, only the first of which has close connection with the just defined notion of convergence of double sequences (at any rate, connection between double series and sequences is less intimate than in the case of single series and sequences):

(a) $\Sigma\Sigma a_{m,n}$ is said to converge to sum s, if the double sequence $\{s_{m,n}\}$ tends to s, in the sense just described, where $s_{m,n}$ denotes the sum of the terms $a_{j,k}$ with $j \leq m$, $k \leq n$; such terms $a_{j,k}$ fill a rectangle in the upper-left corner of the double series table above and the sums $s_{m,n}$ are correspondingly called rectangular partial sums of the series; the kind of convergence which has just been introduced is called the rectangular convergence of the series;

(b) the series $\Sigma\Sigma a_{m,n}$ is said to converge to sum s, if S_R tends to s as R tends to $+\infty$, where S_R is the sum of the terms $a_{m,n}$ with $m^2 + n^2 \leq R^2$; indices m,n satisfying this inequality are coordinates of points situated in the circle with the centre at the origin and radius R, so that it is natural to call the S_R the circular partial sums, and the kind of convergence they generate circular convergence;

(c) $\Sigma\Sigma a_{m,n}$ is said to converge to sum s if the terms in each column of the table form convergent series and if $A_1 + A_2 + \ldots + A_n + \ldots = s$, where A_n is the sum of terms in the nth column of the table; this kind of summation is called summation by columns, and by interchanging the roles of columns and rows leads to a parallel notion of convergence by rows.

These definitions of convergence are not equivalent and a series can converge according to one definition and not according to another. The problem of additional conditions under which the definitions are equivalent is not very difficult but the conditions themselves are not of a simple nature and most (though not all) important series $\Sigma\Sigma a_{m,n}$ in analysis are absolutely convergent (that is $\Sigma\Sigma|a_{m,n}|$ converges). For such series all reasonable definitions of convergence are equivalent and the sum of the series is independent of the definition. Definitions and results can be extended to triple, quadruple, etc. series.

Series of Functions.—Let $\Sigma u_n(x)$ be a series whose terms $u_1(x), u_2(x), \ldots, u_n(x), \ldots$ are functions defined in an interval of the real variable x. If $\Sigma u_n(x)$ converges at each point of the interval the series is said to converge pointwise in the interval. Denote by $f(x)$ the sum and by $s_n(x)$ the partial sums of the series. Pointwise convergence means that, for any positive ϵ, there is an index n_0, depending in general on ϵ and x, in symbols $n_0 = n_0(\epsilon,x)$, such that $|f(x) - s_n(x)| < \epsilon$ for $n > n_0$. If for each $\epsilon > 0$ an n_0 can be found independent of x the series is said to converge uniformly in the interval considered; geometrically this means that for each $n > n_0$ the graph of the curve $y = s_n(x)$ and that of the curve $y = f(x)$ differ by less than ϵ in the whole interval under consideration. Pointwise convergence in general does not preserve properties of the terms of the series. For example, if the $u_n(x)$ are continuous and $\Sigma u_n(x)$ converges pointwise, the sum of $\Sigma u_n(x)$ need not be continuous. A simple example is provided by the series $(1-x) + x(1-x) + x^2(1-x) + \ldots$, which converges at each point of the interval $0 \leq x \leq 1$ and whose sum is equal to 0 for $x = 1$ and equal to 1 at the remaining points of the interval. Similarly, if the $u_n(x)$ are integrable over an interval and the series $\Sigma u_n(x)$ converges pointwise, the sum of $\Sigma u_n(x)$ need not be integrable. The significance of the notion of uniform convergence is that the sum of a uniformly convergent series of functions inherits many important properties of the terms, and in particular continuity and integrability. Not all properties, however, are preserved by uniform convergence; for example, the sum of a uniformly convergent series of differentiable functions need not be differentiable (as a matter of fact, examples of continuous and nowhere differentiable functions are usually given as sums of uniformly convergent series of differentiable functions). The following three theorems about uniformly convergent series are particularly useful.

X. If the functions $u_n(x)$ are continuous in an interval, and the series $\Sigma u_n(x)$ converges uniformly in the interval, the sum of the series is continuous in the interval.

XI. If the $u_n(x)$ are integrable over a finite interval (a,b), and $\Sigma u_n(x)$ converges uniformly in (a,b), then the sum $f(x)$ of $\Sigma u_n(x)$ is integrable over (a,b) and

$$\int_a^b f(x)dx = \Sigma \int_a^b u_n(x)dx$$

XII. If each term of the series $\Sigma u_n(x)$ has a continuous derivative in a finite interval (a,b), and if the series $\Sigma u_n'(x)$ of derivatives converges uniformly in (a,b), then the series $\Sigma u_n(x)$ also converges uniformly in (a,b), its sum $f(x)$ is differentiable and $f'(x) = \Sigma u_n'(x)$.

There are no special tests for the pointwise convergence of series since pointwise convergence simply means ordinary convergence at each point x separately. There are tests for the uniform convergence of a series of functions, among which the following, usually called Weierstrass' M-test, is particularly useful:

XIII. If there are positive constants $M_1, M_2, \ldots, M_n, \ldots$ such that the series ΣM_n converges and $|u_n(x)| \leq M_n$ for each n and all x of an interval then the series $\Sigma u_n(x)$ converges uniformly in the interval.

Only the uniform convergence of series has been considered. There are parallel definitions and results for the uniform convergence of sequences. One can also consider the uniform convergence of double series and sequences. Special types of series of functions are particularly important for various branches of analysis (*see*, for example, FOURIER SERIES). The convergence of series $\Sigma u_n(z)$ whose terms depend on a complex variable $z = x + iy$ may be considered. The most important among them is the case of power series.

Power Series.—Power series are of the form

$$a_0 + a_1z + a_2z^2 + \ldots + a_nz^n + \ldots = \Sigma a_nz^n$$

where the a_n are constants (in general, complex) and $z = x + iy$ is a complex variable; in the symbol Σa_nz^n the index n ranges through the values $0, 1, 2, \ldots, n, \ldots$ Each power series has a circle of convergence; this is a circle (disk) with the centre at the point $z = 0$ and the following properties: the series converges at each point interior to the circle and diverges at each point exterior to the circle. As to the behaviour on the circumference of the circle of convergence, Σa_nz^n may converge at some points, diverge at others. The intersection of the circle of convergence with the real axis is an interval $(-R,R)$ and the series Σa_nx^n, a power series of the real variable x, converges in the interior of this interval, and diverges in the exterior. The radius R of the circle of convergence is called the radius of convergence of the power series. The circle of convergence can degenerate to a point; each power series Σa_nz^n necessarily converges at the point $z = 0$ but may converge at no other point: the series $\Sigma n!z^n$ is an example of this. The circle of convergence may also cover the whole complex plane, as in the series $\Sigma z^n/n!$ Finally the radius of convergence may have any prescribed positive value R since the radius of convergence of the geometric series $\Sigma(z/R)^n$ is precisely R.

At each point interior to the circle of convergence the power series not only converges but converges absolutely. What is very important is that in each circle concentric with the circle of convergence but of smaller radius the power series converges uniformly. Series of the form $a_0 + a_1(z-b) + a_2(z-b)^2 + \ldots = \Sigma a_n(z-b)^n$, where b is a fixed complex number are called power series with centre b. Their study does not require the introduction of new concepts since by replacing $z - b$ with a new variable Z we reduce the series to the previously discussed case Σa_nZ^n. It follows that $\Sigma a_n(z-b)^n$ has also its circle of convergence, but this time the circle has its centre at the point b. Functions representable by power series have very important properties. Listed below are a few basic power series, considering for simplicity only real values of x.

$(1+x)^\alpha = 1 + \alpha x + \dfrac{\alpha(\alpha-1)}{1\times 2}x^2 + \dfrac{\alpha(\alpha-1)(\alpha-2)}{1\times 2\times 3}x^3 + \ldots$ (Newton's binomial series; $R = 1$)

$\ln(1+x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \ldots (R = 1)$

$\text{arc tan } x = x - \frac{1}{3}x^3 + \frac{1}{5}x^5 - \ldots (R = 1)$

$e^x = 1 + \dfrac{x}{1} + \dfrac{x^2}{1\times 2} + \dfrac{x^3}{1\times 2\times 3} + \ldots (R = \infty)$

$\cos x = 1 - \dfrac{x^2}{1\times 2} + \dfrac{x^4}{1\times 2\times 3\times 4} - \dfrac{x^6}{1\times 2\times 3\times 4\times 5\times 6} + \ldots$ $(R = \infty)$

$\sin x = x - \dfrac{x^3}{1\times 2\times 3} + \dfrac{x^5}{1\times 2\times 3\times 4\times 5} - \ldots (R = \infty)$

Divergent Series.—Consider the series $1 - 1 + 1 - 1 + \ldots$ Its partial sums $1, 0, 1, 0, \ldots$ do not tend to any limit; therefore, according to the definition, the series is divergent. On the other hand, the average value of the partial sums $1, 0, 1, 0, \ldots$ is $\frac{1}{2}$, which made some mathematicians as early as the 17th century adopt the point of view that though the series, strictly speaking is divergent it somehow has the sum $\frac{1}{2}$. Such ideas, though for a long time unclear and confused, were finally clarified and led to a logically coherent and fruitful theory of divergent series and sequences. A few facts are here presented. The theories of divergent series and sequences being parallel, sequences are considered first.

Consider a sequence $\{s_n\} = s_0, s_1, \ldots, s_n, \ldots$ (in this context it will be convenient to include 0 as an index). A definition of convergence of $\{s_n\}$ already has been formulated. This definition, which may be called classical, is not the only one possible; alternate definitions could be adopted. The following one is very intuitive. Consider the averages of the successive terms of $\{s_n\}$; these averages will be denoted by $\sigma_0, \sigma_1, \sigma_2, \ldots, \sigma_n, \ldots$ so that

$$\sigma_0 = \frac{s_0}{1}, \sigma_1 = \frac{s_0 + s_1}{2}, \sigma_2 = \frac{s_0 + s_1 + s_2}{3}, \ldots, \sigma_n = \frac{s_0 + s_1 + \ldots + s_n}{n+1}, \ldots$$

It may be said that $\{s_n\}$ converges on the average to limit s if the sequence $\{\sigma_n\}$ converges to limit s in the classical sense. It can be shown that any sequence $\{s_n\}$ which converges in the classical sense also converges on the average, and that the limits are the same in both cases. There are sequences that do not converge in the classical sense but converge on the average (the sequence $\{s_n\} = 1, 0, 1, 0, \ldots$ is an instance in point, since here $\{\sigma_n\} = 1, \frac{1}{2}, \frac{2}{3}, \frac{1}{2}, \frac{3}{5}, \frac{1}{2}, \ldots$ tends to $\frac{1}{2}$). Hence, in adopting convergence on the average as a definition of convergence of a sequence, conflict with the old definition is avoided on the one hand and, on the other, sequences previously considered divergent (and useless) are made convergent. Instead of saying that $\{s_n\}$ converges "on the average" it is now customary to say that $\{s_n\}$ is summable by the method of the first arithmetic mean (*q.v.*). Not every sequence is thus summable. For example, if $s_n = 1, -2, +3, -4, +5, \ldots$, then σ_n does not converge in the classical sense; but it is easy to prove that σ_n is summable by the method of the first arithmetic mean to the limit 0, so that we may say that $\{s_n\}$ is summable to limit 0 by the method of the second arithmetic mean. We could similarly introduce the third, fourth, etc., arithmetic means. It is, however, preferable to adopt a more general point of view.

The averages considered in the definition of $\{\sigma_n\}$ are not the only conceivable ones, since "weighted" averages may be introduced. The general scheme is as follows. Consider a fixed matrix (double array) of numbers denoted by M:

$$\begin{matrix} a_{0,0}, & a_{0,1}, & a_{0,2}, & \ldots, & a_{0,n}, & \ldots \\ a_{1,0}, & a_{1,1}, & a_{1,2}, & \ldots, & a_{1,n}, & \ldots \\ a_{2,0}, & a_{2,1}, & a_{2,2}, & \ldots, & a_{2,n}, & \ldots \\ \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\ a_{m,0}, & a_{m,1}, & a_{m,2}, & \ldots, & a_{m,n}, & \ldots \\ \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \end{matrix}$$

Given any sequence $\{s_n\}$ a new sequence σ_m may be introduced defined by the formulas

$$\sigma_m = a_{m,0}s_0 + a_{m,1}s_1 + a_{m,2}s_2 + \ldots + a_{m,n}s_n + \ldots$$

(in which $m = 0, 1, 2, \ldots$).

Then σ_m may be considered as a weighted average of the num-

bers $s_0, s_1, \ldots$ formed with weights situated in the mth row of the matrix. If $\{\sigma_m\}$ converges in the classical sense to limit s, it may be said that $\{s_n\}$ is summable by the matrix M, or simply summable M, to limit s; s is then the generalized limit of $\{s_n\}$, associated with the matrix M. It is easily seen that the method of the first arithmetic mean is given by the matrix

$$\begin{matrix} 1, & 0, & 0, & 0, & \ldots \\ \frac{1}{2}, & \frac{1}{2}, & 0, & 0, & \ldots \\ \frac{1}{3}, & \frac{1}{3}, & \frac{1}{3}, & 0, & \ldots \\ \ldots & \ldots & \ldots & \ldots & \ldots \end{matrix}$$

Classical convergence corresponds to the matrix whose terms on the main diagonal are all $1 (a_{n,n} = 1$ for all $n)$ and the remaining terms are 0, since then $\sigma_n = s_n$ for all n.

This definition of summability of a sequence was introduced by the German mathematician Otto Toeplitz. It is extremely general, though it could be generalized still further, and raises a very large number of problems which are the subject of the general theory. A few such problems are considered below.

The first question concerns the conditions under which this definition is a genuine generalization of the classical convergence. The answer is that a necessary and sufficient condition that every convergent sequence should also be summable M, and to the same limit, is that (1) the terms of M should tend to 0 in each column separately; (2) the sum of the absolute values of the terms in each row should stay below some constant; (3) the algebraic sum of elements in each row should tend to 1 as the index of the row increases. Many results about summable sequences are corollaries of this theorem. In the special case when the elements of the matrix are nonnegative, condition (2) is essentially a consequence of (3) and can be dropped.

It is said that a method M' is stronger than M if every sequence summable M is summable M', but not conversely, and if the limits in both cases are the same. It may then be asked when a given method M' is stronger than M. Theorems answering this question are called Abelian, after Niels Henrik Abel. If M' is stronger than M we may ask under what additional conditions, for the sequence summability by M' implies summability by M; results of this type are called Tauberian theorems, after the Austrian mathematician Alfred Tauber. The most interesting theorems of Abelian and Tauberian character pertain to specific and important methods of summability.

Given a series $a_0 + a_1 + \ldots + a_n + \ldots$ it may be said that it is summable M to sum s if the sequence of the partial sums of the series is summable M to limit s. To distinguish between series and sequences some writers say that a series is summable while a sequence is limitable, but no confusion arises if the word summable is used in both cases. However, certain forms of summability are more adapted to series than sequences, and vice versa. This situation, in particular, applies to Abel's method of summation, which defines the sum of Σa_n as the limit of $\Sigma a_n r^n$ for r tending to 1 through values less than 1. Abel's method is stronger than convergence, and even stronger than the method of the first arithmetic mean (Abelian theorems). A series that is Abel summable need not converge; for example, the divergent series $1 - 1 + 1 - \ldots$ is Abel summable to sum $\frac{1}{2}$ since $1 - r + r^2 - r^3 + \ldots = 1/(1+r)$ tends to $\frac{1}{2}$ as $r \to 1$. If, however, $a_n \leq 1/n$ for all n, and Σa_n is Abel summable, then Σa_n converges (a Tauberian theorem).

The method of the first arithmetic mean and that of Abel are among the most important ones. Their main applications are to the study of the behaviour of power series on the circumference of their circles of convergence and to the theory of Fourier series. There is a great variety of methods of considerable intrinsic interest and importance in applications. The method of arithmetic means of various orders (hinted at above) has developed into a wide and elegant theory with far-reaching applications. The method of Borel assigns to a sequence $s_0, s_1, \ldots, s_n, \ldots$ the sum

$$\lim_{x \to +\infty} \left\{ e^{-x} \sum_{n=0}^{\infty} \frac{s_n}{n!} x^n \right\}$$

and can sum power series outside their circles of convergence. There is also an extension of the theory to divergent integrals. The importance of the theory of divergent series lies, however, not only in individual results but in the general point of view upon the notion of convergence, a point of view which has had a great impact upon the development of mathematical analysis.

History of Series.—The origin of the modern theory of series precedes that of the calculus and can be associated in the 17th century with the names of Bonaventura Cavalieri, John Wallis, James Gregory and others. In the same century, the discovery of the calculus by Leibniz and Newton gave a very strong impulse to the theory; and the 18th century witnessed considerable progress in the work of Jakob and Daniel Bernoulli, D'Alembert, Leonhard Euler and others. Much of this work was of purely formal character, and mathematical rigour was not the primary concern of the investigators. Though Newton and Leibniz avoided divergent series, formal and uninhibited use of the latter was bringing such mathematical rewards that the temptation was too much to withstand, and divergent series became—mostly through the work of Euler—an accepted tool of investigation. Mathematical instinct of the great mathematicians of the 18th century prevented them, however, from making mistakes and their results, properly interpreted, can now be proved rigorously. Rigorous foundations for the theory of infinite series were laid in the first half of the 19th century by Augustin Louis Cauchy and Niels Henrik Abel; definitions they gave and results they proved can be found in all textbooks of calculus. Their attitude toward divergent series was purely negative, however. (Abel wrote in 1828: "Divergent series are the invention of the devil, and it is shameful to base on them any demonstration whatsoever.") The respect commanded by the work of Cauchy and Abel banished divergent series from mathematics for half a century. Their work on the foundations of the theory of series was continued by others in the 19th century, in particular by Peter Gustav Lejeune-Dirichlet, Georg Friedrich Riemann and Karl Weierstrass. By the last decade of the 19th century the effects of Abel's anathema began to disappear, and the work of Ernesto Cesàro, Émile Borel, Leopold Fejér and others showed that the theory of divergent series can be put on a rigorous basis and is a source of great progress in mathematics. In the 20th century the work of G. H. Hardy and J. E. Littlewood brought major breakthroughs and extended the field in depth. Important progress in Tauberian theorems was made by Norbert Wiener.

SERJEANTS-AT-LAW (SERVIENTES AD LEGEM): *see* LEGAL PROFESSION.

SERJEANTY, in the feudal age, was a form of land tenure granted in return for the performance of some specific service to the lord, whether the king or another. In England, immediately after the Norman Conquest, the king created many serjeanties because he had much land at his free disposal and needed many services—the provision of bows, arrows, and knives, men to keep down vermin in his forests, to serve in his buttery and winecellar and as ushers. It was easier at that time to reward any service with land than with money. But it was uneconomic, and fresh grants of land in serjeanty became rare by the late 12th century. The tenure was widespread, and the Domesday account of every county ends with a list of the king's serjeants. Tenants by serjeanty were subject to the feudal dues of wardship, marriage, and relief, but they paid no scutage (*q.v.*) since they performed no

knight service (*see* KNIGHT SERVICE). Land held by serjeanty could not by law be sold or divided among heirs. Since by the 13th century much alienation (*i.e.*, transfer by deed) and subdivision had, however, actually taken place, an inquiry into the tenure was made in 1250 under Robert Passelewe, deputy treasurer. As a result, the holders of the alienated portions were mostly required to pay rent or do a quota of knight service, and the unalienated portion remained charged with the original duty. A statute of 1324 (17 Edw. II c. vii) provided that a "reasonable" fine was owed to the crown by serjeants who alienated their serjeanties "without the king's licence."

The miscellaneous nature of the services due to the king by his serjeants resulted in the inaccurate conception of serjeanty as falling into two divisions: grand serjeanty, a tenure so noble that it ranked socially above knight service, and petty serjeanty, a tenure so meagre that it ranked with the peasants' tenure, socage (*q.v.*). In origin there was no distinction between serjeanties, but inevitably those which brought their holders into immediate contact with the sovereign acquired prestige and became known as grand serjeanties. *See* also ENGLISH LAW: *Norman Feudal Land Law.*

SERLIO, SEBASTIANO (1475–1554), Italian architect and theorist, the founder of the classical school of architecture in France, was born at Bologna on Sept. 6, 1475. He worked in Rome with Baldassare Peruzzi from 1514 until the sack of the city in 1527, when he fled to Venice. Peruzzi bequeathed him all his own drawings, and these were put to good use by Serlio in his *Treatise*, his greatest achievement. The first part of it, published in 1537, was really Book iv of the complete *Treatise* but was soon reprinted and translated as an independent work (Eng. trans., 1611).

Book iii followed in 1540, and in 1541 Serlio moved to France, where he was supported for six years by Francis I. Books i and ii came out in 1545, Book v in 1547, Book vi exists only in manuscript, Book vii was published posthumously in 1575, but there is a manuscript of (apparently) an eighth book in Munich. Most important of all, Serlio published an *Extraordinario Libro* in 1551 which contains 50 fanciful designs for doorways. These were much copied in northern Europe.

Serlio's *Treatise* as a whole was very influential because it was essentially a practical handbook of the antique style and presented a number of models for copying; it was fundamentally a set of illustrations linked by commentary rather than an essay on archaeology or aesthetics. The only surviving buildings which can be connected with Serlio are one doorway at Fontainebleau and the château of Ancy-le-Franc in Burgundy. He died at Fontainebleau in 1554.

See W. B. Dinsmoor in *Art Bulletin*, xxiv (1942), and A. F. Blunt, *Art and Architecture in France, 1500 to 1700* (1953). (P. J. MY.)

SERMON: *see* PREACHING.

SERMON ON THE MOUNT, the popular name for Matt. 5–7, the longest discourse of Jesus in the Synoptic Gospels. In it are concentrated the most familiar ethical teachings of Jesus; however, they are so thoroughly founded upon the insuperable demand of God as to be sharply distinct from any merely humanistic ethic. In brief outline the sermon contains: (1) nine blessings, 5:3–12 (*see* BEATITUDES); (2) salt and light, 5:13–16; (3) validity of the Law, 5:17–20; (4) ". . . but I say to you . . . ," interpretations of six demands of the Law, 5:21–48; (5) three acts of piety (almsgiving, prayer, fasting) with (6) the Lord's Prayer (*q.v.*) appended to the second, 6:1–18; (7) true and false treasure, 6:19–34; (8) miscellaneous ending, mostly warnings (against self-righteous judgment, against profaning the holy, God's response to prayer, the Golden Rule, against any easy way to Life, against false prophets, against serving God by word only), 7:1–23, illustrated by the simile of a house with and without foundation, 7:24–27, and an editorial conclusion, 7:28 ff.

Most of these sayings have parallels in Luke, of which about half occur in Luke's much shorter Sermon on the Plain (6:20–49, named from Luke 6:17) and in nearly the same order; Luke's remaining parallels are scattered through his chapters 11–16. This parallelism suggests either that the author of Luke (*see* LUKE, GOSPEL ACCORDING TO SAINT) dispersed what had come down to him as a sermon or that the author of Matthew (*see* MATTHEW, GOSPEL ACCORDING TO SAINT) editorially composed a sermon out of mostly scattered sayings offered him by tradition. From the clearly discernible literary habit of the Gospel of Matthew to organize the words of Jesus into connected complexes concluding with "And when Jesus had finished these sayings . . . ," the latter possibility is the probable one. The plan and some basic material of the sermon were furnished by what is common to the Sermon on the Mount and the Sermon on the Plain; *i.e.*, by a definite section of the lost source common to Matthew and Luke, whether this was a written document or only crystallized and memorized tradition.

Neither the "mount" nor the "plain" is given a name and it is idle to attempt to identify either. The source evidently did not localize the discourse, but apparently did suggest that it was of one piece. Whether the latter is true is neither determinable nor centrally important. What is important is that the sermon contains some of the most certain and characteristic utterances of the historical Jesus.

See M. Dibelius, *The Sermon on the Mount* (1940). (KE. G.)

SEROV, a town in Sverdlovskaya (Sverdlovsk) Oblast' of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the left bank of the Kakva, a tributary of the Sos'va. Pop. (1959) 97,882. Originally known as Nadezhdinsk, the town developed as a centre of the Urals ironworking area. Although its development in the 1890s was late for the Urals, it soon became the largest pre-Revolutionary ironworking town in the area, making rails for the Trans-Siberian Railway. Today it is the main centre of the northern Urals mining and metallurgical region, with iron ore, bauxite, manganese, gold, and lignite obtained nearby. It produces high-grade steel. The lignite is used in the thermal power station. (R. A. F.)

SEROWE, town in Ngwato district, Bechuanaland (Botswana) Africa, lies 3,800 ft. (1,158 m.) above sea level, 30 mi. (48 km.) WNW of Palapye Road on the Cape to Congo railway, 200 mi. SW of Bulawayo, Rhodesia, and 245 mi. (394 km.) NNE of Mafeking, S.Af. Pop. (1964) 33,592. The chief town of the Ngwato tribe and the headquarters of the tribal administration, it has several government offices, a hospital, and an airfield. The European population consists largely of traders. Serowe was first occupied by the Ngwato in 1902 after they had abandoned their earlier home in Palapye. The statue of a duiker stands in memory of chief Kgama III, tribal leader until 1923. (AY. SY.)

SERPENTINE, a group of hydrous magnesium silicates with iron, nickel, and manganese commonly substituting for magnesium. The iron gives it a variety of green (although sometimes yellowish and brownish) colours; the pure material is grayish to white. When mottled with red the colour is due to a physical mixture of excess iron oxide. The usually massive serpentine rock may be composed of a mixture, the fine fibrous variety known as chrysotile and antigorite, both of the same composition but differing in crystal structure. Other varieties are identified by X-ray diffraction techniques.

Chrysotile serpentine, when found unmixed with antigorite and with long fibres, is used for most of the asbestos (*q.v.*) of commerce although some asbestos does come from the amphibole group of minerals.

Serpentine is a secondary mineral generally formed by the hydration of the magnesium silicates in peridotite, an olivine and pyroxene (*q.v.*) rich rock. The composition of serpentine is $Mg_3Si_2O_5(OH)_4$, so commonly both H_2O and SiO_2 must be added to an existing composition to form serpentine, especially in the magnesium carbonate rocks. This is a process that generates heat and requires an increase in volume for a large mass to develop. However, occasional distinct crystals show the form of olivine, pyroxene, or amphibole that has been replaced forming a pseudomorph which may grow by some leaching process. The density

of serpentine is about 2.5 to 3.0. It cleaves easily parallel to the plates in the variety antigorite or to the fibres in the variety chrysotile. It has a waxy feel and appearance and takes a high polish after carving or cutting as a gem or ornamental stone (verd antique).

(*See* also MARBLE; STONE.)

Serpentine occurrence is extremely widespread. It is characteristically found along the crests and axes, the low-pressure areas, of great folds whether island arcs or alpine mountain chains. These massive serpentines are commonly produced by metamorphism (*q.v.*) of peridotite, and indicate a development in these major structures of the earth's crust that progressed simultaneously with the growth of the fold system and may have continued after the mountain building ceased.

The serpentines along island arcs outcrop over areas covering from hundreds to thousands of square miles, as in New Caledonia and Cuba, and may be exposed by erosion or perhaps a solid extrusion.

(K. O. B.)

SERPENT MOUND, GREAT, a prehistoric American Indian earthwork in Ohio on a narrow spur between Brush Creek and East Creek, Adams County. Feature attraction of Serpent Mound State Park, the effigy is 1,330 ft. (405 m.) long with seven serpentine convolutions, 15 to 20 ft. (4 to 6 m.) wide in the body, and 3 to 5 ft. (1 to 2 m.) high. The tail section has three coils, while the head is reconstructed as a serpent's open mouth. An oval embankment, 125 ft. long and 60 ft. wide, protrudes from the open mouth. Carefully excavated sections of the body and the oval disclosed a foundation of stone, ashes, and clay. There was no definite information as to the meaning of this effigy in the 1960s; apparently it had considerable importance as a symbol of religious beliefs. Serpents have had a prominent place in the mythology and folklore of Indians of the Mississippi and Ohio valleys. Materials excavated from conical mounds and a village site to the south of the serpent indicate that this Adena Culture effigy was constructed about 2,000 years ago.

SERPUKHOV, a town in Moscow Oblast' of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on both banks of the Nara River at its confluence with the Oka, 62 mi. (100 km.) S of Moscow. Pop. (1959) 106,387. The town was founded in 1374, although a settlement existed there earlier. It was one of the major strongholds protecting Moscow from attack from the south by the Tatars, and was sacked in 1382 and 1408. Ivan IV, the Terrible, built stone fortifications in 1556. Lying on the main route south from the capital (now on the trunk railway and highway from Moscow to the Crimea), the town soon became an important centre of trade and crafts, especially sailmaking. In the 19th century textile manufacture was developed and modern Serpukhov is one of the chief textile towns of the Moscow region, concentrating on cotton spinning and weaving and the production of cotton prints. Artificial silk is also made. The engineering industry is important, producing motor invalid carriages, machine tools, hydraulic presses, gasoline pumps, metal files, and parts for textile machinery. Concrete pipes and foodstuffs are also produced. (R. A. F.)

SERRA, JUNÍPERO (1713–1784), Spanish Franciscan missionary in America, known as the Apostle of California, was born on the island of Majorca, Nov. 24, 1713. After entering the Franciscan order in 1730, he became a university professor and distinguished preacher. In 1750 he arrived in Mexico City for missionary work among the Indians. Serra laboured in the Sierra Gorda missions for eight years, then became a circuit missionary in south-central Mexico until 1767. He was president of the Lower California missions, 1768–69.

When José Gálvez ordered the occupation of Upper California, Serra joined the expedition of Gaspar de Portolá (*q.v.*). On July 16, 1769, he founded Mission San Diego, the first within the present state of California. Between 1770 and 1782 he founded eight additional missions: San Carlos at Monterey (1770), changed to Carmel in 1771, which became Serra's headquarters; San Antonio and San Gabriel, the latter near Los Angeles (1771); San Luis Obispo (1772); San Francisco (Mission Dolores) and San Juan Capistrano (1776); Santa Clara (1777); and San Buenaventura (1782). He introduced cattle, sheep, grains, and fruits from Mexico. A strenuous defender of the Indians, Serra died at San Carlos, Aug. 28, 1784, and is there buried. The cause for his beatification has been introduced. A statue of Junípero Serra represents California in the National Statuary Hall in Washington. *See* also CALIFORNIA: *History: Missions.*

SERRAI (SERRES), the chief town of the Serrai *nomos* (department) of Greek Macedonia, 43 mi. (69 km.) NE of Salonika. Pop. (1961): 40,063 (town), 248,041 (*nomos*). The town stands at the foot of the hills on the eastern side of the valley of the Struma (Strymon) River, and commands the route through the Rupel Pass into Bulgaria. It is the seat of the metropolitan bishop of Serrai and Nigrita and consists of the old quarter, Varosh, situated at the foot and on the slope of the hill crowned by the old castle, and of the new town, built on the plain and forming the commercial centre. The district is remarkably fertile, and there is a large trade in rice and cereals; other exports include tobacco, cotton, and hides.

Serrai is the ancient Siris in Paeonia, later called Sirrhae. It was fortified by the Byzantine emperors to guard the road between Thessalonica (Salonika) and Constantinople (Istanbul), and to serve as a stronghold on the Bulgarian frontier. It was unsuccessfully attacked by the Bulgars in the 10th century and again in 1195–96. The Serbians conquered it in 1345, but it was retrieved by the Byzantines in 1371, before falling to the Turks in 1383. It remained Turkish until 1913, when it was looted and burned by Bulgarian troops during the Greek advance up the Struma valley. It later passed into Greek territory, but was occupied by the Bulgarian army from 1916 to 1918, and suffered severely from bombardment. After 1922 there was a great influx of Greek immigrants. During World War II it was again occupied by Bulgaria, from 1941 to 1944.

SERRANO Y DOMINGUEZ, FRANCISCO, DUQUE DE LA TORRE (1810–1885), Spanish general and statesman, a leader of the Revolution of 1868 and regent of Spain from 1869 to 1870, was born at San Fernando, Cádiz, on Oct. 17, 1810. He joined the army at the age of 12 and during the First Carlist War (1833–39) received rapid promotion. In 1839 he became brigadier and was elected deputy to the *Cortes* for Málaga. Supporting Baldomero Espartero, Serrano voted for him to take over the regency and Espartero made him field marshal (1840). However he later became Espartero's opponent, conspiring with Gen. Juan Prim and Luis González Bravo to drive him into exile in 1843. Serrano was captain general of Granada from 1847 to 1848. In 1854 he supported the *pronunciamiento* of Leopoldo O'Donnell, and was captain general of Cuba from 1859 to 1862, when he was created duque de la Torre.

On his return to Spain in 1863 he became minister of state in O'Donnell's government. He helped to suppress the rising at San Gil, in Madrid, in June 1866 and was rewarded with the Order of the Golden Fleece. In 1867 he succeeded O'Donnell as leader of the Union Liberal Party.

Serrano was deported to the Canary Islands in July 1868 for plotting against Isabella II, but in September he returned to take part with Adm. Juan Topete y Carballo and Prim in the rising at Cádiz, defeating Gen. Manuel Pavía y Lacy at Alcolea later in the month. Isabella was exiled and Serrano formed a provisional revolutionary government. In 1869 the *Cortes* elected him regent. After Amadeo of Savoy was proclaimed king of Spain (November 1870), he entrusted Serrano with the task of forming a new government.

On Amadeo's abduction (February 1873) and the establishment of the First Republic, Serrano went into exile at Biarritz, returning to Spain shortly before the *coup d'état* of Gen. Manuel Pavía

y Rodríguez de Alburquerque in January 1874. Serrano was elected president of the executive and concerned himself with the pacification of the north of Spain. The *pronunciamiento* of December 1874, which restored the Bourbons in the person of Alfonso XII, took Serrano by surprise. Excluded from the government, he formed the left-wing Liberal group. He died in Madrid on Nov. 26, 1885.

(R. S. LL.)

SERTORIUS, QUINTUS (*c.* 123–72 B.C.), Roman statesman and military commander of genius, leader of an effective revolt against the Roman Senate and for eight years supremely powerful in Spain, was born at Nursia (modern Norcia), in central Italy. After acquiring some reputation in Rome as a jurist and orator, he fought in Gaul against the invading Cimbri and Teutones (105 and 102), and in 97 he served in Spain. In 90 he was quaestor in Cisalpine Gaul.

In the struggle between L. Cornelius Sulla (*q.v.*), and Gaius Marius (*q.v.*), Sertorius supported Marius (*see* also ROMAN HISTORY: *The Social War and Sulla's Dictatorship*). He was praetor in 83, and in 83 or early 82 escaped to his appointed province of Nearer Spain. When Sulla sent two legions against him he retreated to Africa. In 80 he returned to Spain, where he was joined by many Roman refugees and deserters and by Spanish volunteers. With this army he successfully fought the Sullan governor of Farther Spain, Q. Metellus Pius.

For some years Sertorius ruled Spain as in effect an independent state. He was in league with the Mediterranean pirates and negotiated with Mithradates VI of Pontus, as fellow enemies of the Roman government. In 77 he was joined by M. Perperna and other supporters of the unsuccessful rebel Lepidus (*q.v.*), but in the same year Pompey (*see* POMPEIUS: *Gnaeus Pompeius Magnus*) was sent to Spain with an army. During the next two years Sertorius demonstrated his skill as a strategist and tactician against both Pompey and Metellus. In 74, however, the tide turned against Sertorius. The Iberians lost heart, he was driven to take harsh measures to maintain order, and his formerly great popularity declined. In 72 he was murdered in a conspiracy headed by Perperna.

Sertorius was in revolt perhaps less against Rome than against the constitution Sulla had imposed on Rome. His object in Spain was to build up a stable government with the cooperation of the people, to whom he wished to bring Roman civilization. He established a Senate of 300 members, drawn mainly from Roman emigrants but probably with a few Spaniards, and his bodyguard was composed of Spaniards. Strict and severe with his soldiers, he was considerate to the people. He was accompanied everywhere by a white fawn, which was supposed to communicate to him the advice of the goddess Diana and which promoted his popularity among the superstitious tribesmen.

SERUM THERAPY. Serum, the liquid cell-free fraction of the blood, contains among other chemicals proteins called globulins. Linked to the globulins are antibodies, which are chemical fractions elaborated by the body in response to the presence of foreign proteins (antigens), some of which are toxic. The purpose of antibodies is to neutralize agents which are harmful to the organism.

The chemical structure of any toxic material is well defined and the corresponding antibody produced by the organism is highly specific, chemically exact, and limited in its action to the substance against which it is formed. Serum therapy, broadly defined, is the administration of serum to a sick person or animal to provide one or more fractions that are lacking or deficient; in the limited, classical definition it is the injection of serum for the beneficial effect of the antibodies on infection in the patient. In this sense serum therapy is also called passive immunization, since antibodies formed in the blood of another person or animal are merely transferred. It differs from vaccine therapy (*q.v.*), or active immunization, in which benign doses of toxins or of disease organisms (alive or dead) are introduced into the bloodstream to stimulate antibody production.

History.—Paul Ehrlich (*q.v.;* 1854–1915) developed the active-immunization theory. In 1890 Emil von Behring (*q.v.*) applied and extended this basic principle of immunology to prepare diphtheria antitoxin. This was done by repeated injections of diphtheria toxin (a poison elaborated by the diphtheria organism) into horses. The vaccination provoked formation of antibodies against the diphtheria toxin. Vaccinated horses were then bled and serum was prepared. Von Behring's theory that the administration of antibodies in the serum should neutralize the toxin in the tissues of diphtheria patients was quickly confirmed by the results. Treatment with the antitoxin had a dramatic effect on persons who contracted this severe disease: mortality declined from more than 33 to less than 5%. Also, children exposed to diphtheria infection but treated with serum escaped the disease. The serum thus proved to have prophylactic value, although the protection thus conferred was only temporary and each separate exposure required an injection.

The success of diphtheria antitoxin prompted scientific workers to attempt to produce antibody serums (antiserums) against other diseases. Most of the early efforts ended in failure. Over the years, however, antiserums were developed and used with moderate success in treating tetanus, epidemic meningitis, gas gangrene, scarlet fever, pneumonia, botulism, and especially poisoning from snakes and insects. Some serums, prior to the development and extensive use of good vaccines, were widely used for prophylaxis. This was especially true of diphtheria and tetanus antitoxin. In general, antiserums against bacterial toxins (antitoxic serums) were the most effective, whereas antiserums to combat bacteria themselves (antibacterial serums) were relatively ineffective.

Effective vaccines and chemotherapy have served to reduce the need for therapeutic or prophylactic antiserums. Widespread immunization against diphtheria, tetanus, and pertussis (whooping cough) so greatly reduced the incidence of these diseases that the need for serum therapy became very limited. Even the effective and historic diphtheria antitoxin was, in the 1960s, required only occasionally.

Types of Serum and Their Uses.—Serum prepared from the blood of healthy adult human beings is called normal human serum and is used principally in shock or in cases of protein deficiency. Serum is also prepared from blood of persons lately recovered from certain acute infections; *e.g.*, scarlet fever, measles, mumps and poliomyelitis. This is called human convalescent serum and is used to a variable extent for prophylaxis or treatment of the specific disease. The effectiveness of human convalescent serum depends on the fact that antibodies resulting from infection are at a peak level in the circulation soon after recovery from the illness.

Serum is also prepared from adults who have been intensively treated with vaccines; this human hyperimmune serum finds principal use in the prevention and treatment of pertussis and mumps. Human serums are generally preferred to animal serums because their injection into patients is usually free from the undesirable reactions (serum sickness) sometimes encountered with the use of animal serums. However, for obvious reasons, supplies of human serum are definitely limited, especially in the case of convalescent or hyperimmune serums. One of the fortuitous developments with the use of human serum was a method, evolved by Edwin J. Cohn, of fractionating the blood proteins in pure, concentrated, and stable form. One of the protein fractions, gamma globulin, found valuable use as a preventive of measles, in the same manner as measles convalescent serum. Since the supply of human gamma globulin is much greater than that of convalescent serum, it is widely used to prevent the disease or modify its severity.

Animal serums, prepared from the blood of horses or rabbits, are of the hyperimmune variety. The animals are treated with an intensive and repeated course of vaccination of the specific agent

such as diphtheria toxin, tetanus toxin, cobra venom, etc. When laboratory tests indicate that a satisfactory level of antibodies has been elaborated, blood is collected, from which serum is prepared. Such serum is further chemically processed, concentrated to make it more effective, and purified to reduce those alien substances in the animal serum which cause undesirable reactions.

A broader use of serum as an agent in combating shock from hemorrhage, trauma, burns, etc., was developed in 1940. Human serum and plasma (serum being the liquid fraction of clotted blood while plasma is the liquid fraction from unclotted blood and contains the clotting elements, prothrombin and fibrinogen) found extensive use for this purpose and was considered one of the three or four great medical weapons of World War II. The value of serum or plasma in shock or hemorrhage is that it provides the fluid and proteins to the circulation so that the vital tissues can be adequately oxygenated by the oxygen-bearing red blood cells. Illnesses accompanied by or resulting in a deficiency of circulating blood protein are also treated with human serum or plasma.

SERVETUS, MICHAEL (MIGUEL SERVETO) (1511?–1553), Spanish theologian and physician, whose execution as a heretic at Geneva led to severe criticism of John Calvin, was born at Tudela or Villanueva in 1511 (or, less likely, 1509). He studied law in Toulouse and on his own also the Bible, with special reference to the Trinity. In Feb. 1530 he accompanied his patron, the Franciscan John de Quintana, to the coronation of the emperor Charles V at Bologna; but he was so distressed by the papal pomp and by the emperor's deference to the worldly pope that he left Quintana and visited Lyons, Geneva and Basel. At Basel he met John Oecolampadius and discussed the trinitarian problem with him. He moved on to Strasbourg, where he met Martin Bucer, exchanged views with Kaspar von Schwenckfeld on the celestial flesh of Christ, and became acquainted with the local Anabaptist community. He published his new ideas on the Trinity in *De Trinitatis erroribus libri vii* (1531), attacking the orthodox teaching and attempting to reconstruct a view of his own, namely, that the Word is eternal, a mode of God's self-expression, whereas the Spirit is God's motion or power within the hearts of men. The Son is the union of the eternal Word with the man Jesus. Servetus' bold and scarcely lucid speculative effort made him odious to both Catholics and Protestants, who found themselves better informed on what he opposed than on what he was trying to formulate. He thereupon published a revised formulation, *Dialogorum de Trinitate libri ii* (1532).

Moving to Lyons under the name Villanovanus, Servetus edited scientific works and published a translation of Ptolemy's *Geography*. Around 1534 a rendezvous was arranged with John Calvin in Paris for the purpose of discussing several theological questions, but Servetus failed to arrive; the two were not to meet until nearly a score of years later. Servetus' writings in this period were a defense (1536) of his friend Leonard Fuchs, the botanist, a book significant because it shows Servetus' growing interest in medicine and physiology; and a treatise, *Syruporum universa ratio*, published in Paris in 1537, the year he moved there. He also published (1538) a work on astrology, became interested in the influence of the stars on health and was subjected to an attack by the Paris medical faculty on account of it. He matriculated in medicine at Paris in 1538 and was associated with Vesalius.

After brief residences in Louvain, Avignon and Charlieu, Servetus became physician to the archbishop in Vienne, where he worked also as an editor; while outwardly a conforming Catholic, he pursued his private theological studies and was presumably rebaptized in 1541. He later asserted that, in imitation of Christ, every believer should be immersed at the age of 30. About this time he wrote *Declarationis Jesu Christi filii Dei libri v* (until recently ascribed to an otherwise unidentified Alphonsus Lyncurius Terraconensis). This comprehensive work anticipates his magnum opus. In 1542 his *Biblia sacra ex Santis Pagnini tra[ns]latione* appeared at Lyons, remarkable for its theory of prophecy in the notes.

In 1546 Servetus opened a fatal correspondence with Calvin, forwarding the manuscript of an enlarged revision of his ideas, the *Christianismi Restitutio*, and expressing a desire to confer with the reformer in Geneva. After the first few letters, Calvin would have nothing more to do with him, kept the manuscript, and said to Guillaume Farel that if Servetus should ever come to Geneva he would not permit him to leave alive. Servetus rewrote the manuscript and had an edition of 1,000 copies secretly printed at Vienne (1553). It was in this comprehensive, systematic theology, in connection with the problem of the relationship of the Spirit and regeneration, that he almost incidentally made known his discovery of the pulmonary transit of the blood. (*See* HARVEY, WILLIAM: *Harvey's Work on the Circulation.*) The assumption of the book is that both God the Father and Christ his Son had been dishonoured by the Constantinian promulgation of the Nicene formula (*see* CREED: *Nicene Creed*), which obscured the redemptive role of Christ and brought about the fall of the church. Servetus, not without a streak of vainglory, felt that he could restore the church by separating it from the state and employing in theological formulations and church practice only that which could be proved from Scripture and the pre-Constantinian Fathers.

A former citizen of Lyons then living in Geneva (Guillaume de Trye) secured some of the letters written by Servetus to Calvin and exposed him to the inquisitor-general at Lyons. Servetus and his printers were seized. Servetus was able to contrive his escape during the trial, and the Catholic authorities had to be content to burn him in effigy. He quixotically appeared in Geneva, was recognized and arrested. His trial, in which Calvin took a prominent part, lasted from Aug. 14 to Oct. 25, 1553, and involved correspondence with the other Reformed Swiss churches in search of judicial and theological counsel. Their spokesmen agreed that Servetus had to be punished as a heretic, but they did not mention the death penalty. Servetus was found guilty mainly on two theological charges (the Trinity and baptism) and was sentenced and burned alive at Champel, Oct. 27, 1553. Calvin had pressed for execution, although by beheading rather than by fire.

The denial by Servetus of three equal persons in the Godhead, along with his belief in the celestial flesh of Christ, in Anabaptism and in psychopannychism (the sleep or even the death of the soul with the body), resulted in his condemnation by both the Catholics in Vienne and the Protestants in Geneva, despite his intense Biblicism, his passionate devotion to the person and work of Christ, and indeed his entirely Christocentric scheme of the universe. What Calvin regarded as pantheism can be best understood as a combination of revealed and natural theology in which the incarnation of the Word was paradigmatic of the process by which creative Light was ever penetrating matter to form created things. Among the few immediate followers was Peter Gonesius in Poland, who seems to have introduced the baptismal theology of Servetus, with its stress on immersion and regeneration, into Polish Antitrinitarianism. His execution produced a Protestant controversy on the death penalty for heresy, in which, among others, Theodore Beza (for) and Sébastien Castellio (against) took part.

SERVICE, ROBERT WILLIAM (1874–1958), Canadian poet and novelist known for his ballads of the Yukon, was born at Preston, Eng., on Jan. 16, 1874, and educated at Hillhead Public School, Glasgow. He went to Canada in 1894 and settled

for a short time on Vancouver Island. He entered the Canadian Bank of Commerce in Victoria, B.C., and was afterward transferred first to Whitehorse in the Yukon and then to Dawson. In all he spent eight years in the Yukon and traveled widely. During his last years with the bank, he wrote verse describing life in the north, notably *Songs of a Sourdough* (1907) and *Ballads of a Cheechako* (1909), both of which were enormously popular. In 1910 appeared a novel, *The Trail of '98*, giving a vivid description of men and conditions in the Klondike. During the Balkan War of 1912–13, Service was war correspondent to the *Toronto Star*. He served this paper in the same capacity during World War I, in which he spent two years as an ambulance driver in the Canadian Army medical corps. He described his war experiences in *Rhymes of a Red Cross Man* (1916). His other early works include *Rhymes of a Rolling Stone* (1912); *Ballads of a Bohemian* (1920); and *The Roughneck* (1923). He returned to Victoria for a time during World War II but later lived in retirement on the French Riviera, where he died on Sept. 11, 1958. Two autobiographical volumes, *Ploughman of the Moon* and *Harper of Heaven*, appeared in 1945 and 1948 respectively. His later collections of ballads include *Songs of a Sun Lover* (1949); *Lyrics of a Low Brow* (1951); *Rhymes of a Rebel* (1952); *Songs for My Supper* (1953); *Carols of an Old Codger* (1954); and *Rhymes for My Rags* (1956). (A. J. M. S.)

SERVICE CLUB, an organization, usually composed of business and professional men or women, that promotes friendliness among its members and is devoted to the principle of service to society. The typical service club combines fellowship and volunteer community service with emphasis on good citizenship and high ideals. All have high-principled mottoes and creeds such as Rotary's "Service Above Self." About half of these clubs are in semirural communities and have memberships of less than 50. Most hold a luncheon or dinner meeting each week. The larger service organizations publish magazines that report their activities and also carry articles of general interest by well-known writers. Many of the service organizations have clubs in more than one country and endeavour to promote international goodwill. They take pride in the international spread of their influence and practices, and they show an awareness and an understanding of conditions in countries in which they have common fellowship.

The term has an entirely different meaning in the U.S. armed forces. A service club in military terminology is a social and recreational club for enlisted personnel.

The civilian service club idea originated in 1905 with Paul P. Harris, a young attorney in Chicago, Ill. His plan of organization envisioned all the essential features of the present-day service club and included the classification principle that restricts membership in a given club to a quota from each business or profession. Because meetings were to be held in rotation in members' offices, Harris proposed the name Rotary. Growth was rapid and in 1907 community service was made a part of the club activities. In 1908 the Rotary movement spread to California and a club was formed in San Francisco. With the formation of clubs in Winnipeg, Can., Dublin, Ire., and London, Eng., the name International Association of Rotary clubs was adopted but was replaced in 1922 by the name Rotary International. By 1912 there were 50 Rotary clubs with 5,000 members, and the service-club movement was well under way. Fifty years later there were more than 8,000 Rotary clubs with a total membership exceeding 400,000.

Other clubs of somewhat similar design followed in rapid succession. In 1911 in Detroit, Mich., a group of businessmen who for many years had been meeting informally at luncheon organized the first Exchange club. Others followed this example and in 1917 the National Exchange club came into being, adopting as its motto "Unity for Service."

In 1912 in Kansas City, Mo., a physician, George W. Smith, finding his classification in the Rotary club already filled, founded Sertoma (International), a name derived from the slogan "Service to Mankind." Gyro (International) came into being in the same year in Cleveland, O., taking as its emblem the gyroscope, signifying stability.

In 1915 Kiwanis (International) was organized in Detroit, the name being derived from Indian lore suggesting self-expression. Its purpose is to promote "the adoption and application of higher social, business, and professional standards" and the development of "intelligent, aggressive and serviceable citizenship." Kiwanis clubs may select two members from each business or profession. The organization has expanded its influence by sponsoring Key club (International), a service club for high school boys, and Circle K (International), a similar organization for college men.

The International Association of Lions clubs was organized in Dallas, Tex., in 1917. Lions clubs adopted more lenient rules for admission and did not follow the classification principle rigidly. As a result, their membership increased rapidly and the Lions club soon became the largest of the service club organizations. By the 1960s there were more than 16,000 Lions clubs with approximately 660,000 members. The organization emphasizes good citizenship, patriotism, education, safety, aid to the blind and support of the United Nations.

In 1919 a group of independent clubs met in Louisville, Ky., and formed Optimist (International), pledged to developing optimism as a philosophy of life. In 1923 the Optimists decided to direct their charitable work toward helping boys.

Civitan (International), with its motto "Builders of Good Citizenship," started in Birmingham, Ala., in 1920 and was dedicated to displaying the Golden Rule in action.

The story of King Arthur inspired the naming in Oakland, Calif., in 1922 of the Loyal Knights of the Round Table (now Round Table International), which has for its motto: "He who seeks to serve another, best serves himself."

In 1928 Ruritan (National) was founded in Holland, Va., with the specification that its membership be one-third rural, one-third business and professional men, and one-third chosen from either category. It uses the service-club technique to encourage a closer union between farmers and men in business and the professions. Most of its clubs are located in towns of 5,000 population or less.

Cosmopolitan (International) was organized in Oklahoma City, Okla., in 1933.

The year 1922 marked the founding in the United States of two young men's service clubs—Active (International) and 20–30 (International), both of which restricted membership to approximately the same (20–40) age group. Round Table (International), founded in 1926 in Norwich, Eng., grew rapidly and formed clubs in Europe, Asia, Africa and New Zealand. These three international organizations together with the Association of Kin(smen) clubs (Canada) and the Association of Apex clubs (Australia), grouped themselves in 1945 into the World Council of Young Men's Service clubs.

In 1960 Active and 20–30 combined to form Active 20–30 International; at the 1960 World council meeting Round Table International was disbanded, and each country entered the council as a national association.

The service-club movement is not limited to men's organizations; there are also several women's service clubs. Among these the pioneer is Altrusa (International), organized in Nashville, Tenn., in 1917 "to help solve community and world problems and promote international understanding." Following Rotary's example, it admits to each club only one member of a specific business or profession. Quota club (International) owes its origin in 1919 to the Kiwanis club of Buffalo, N.Y. It is a civic service club of women holding executive positions or owning their own businesses. Zonta (International), a classified civic service organization of women in business and the professions, was founded in 1919. In the same year the National Federation of Business and Professional Women's clubs was founded. It grew out of the work women performed during World War I and is the largest of the women's service organizations. The name of the American, European and British federations of Soroptimist clubs is compounded from the Latin words *soror* meaning "sister" and *optima* meaning "best." Pilot club (International) was formed in 1921 with the aid and counsel of the Rotary club of Macon, Ga.

It is estimated that each year service clubs carry on several hundred thousand local community projects, ranging in complexity from sponsoring Easter-egg hunts to building and equipping hos-

pitals or summer camps for underprivileged children. Most service organizations support youth activities. Exchange clubs conduct a nationwide model-airplane competition for teen-agers. Lions clubs operate a school for guide dogs for the blind. Rotary International has one of the most ambitious international programs; it administers a multimillion-dollar fund to provide scholarships for graduate students to study in countries other than their own and to become better acquainted with people of other lands. A Kiwanis publication visualizes the service club as "only the first step toward what may well be complete understanding and cooperation among men—the millennium of permanent peace and universal good will."

SERVITES (SERVANTS OF MARY; ORDO FRATRUM SERVORUM SANCTAE MARIAE; O.S.M.), an order of mendicant friars of the Roman Catholic Church founded by St. Bonfilius of Florence and six fellow merchants in 1233. These men were canonized in 1888 and are invoked collectively as the "Seven Holy Founders" (feast Feb. 12). The first approbation of the new order was given by the cardinal legate in Tuscany in 1249; final papal approval was granted by Benedict XI in 1304.

The seven founders of the order first withdrew outside the gates of Florence to live a life of witness based on a literal interpretation of the gospel: a life of poverty and fellowship. After 1240 they departed for Monte Senario about 12 mi. from the city where they continued their penitential life and laid the eremitical foundations of the order. The Rule of St. Augustine was adopted (*see* AUGUSTINE OF HIPPO, RULE OF ST.), and the earliest extant redaction of the Servite constitutions shows heavy Dominican influence.

The order was saved from suppression and greatly propagated by its fifth prior general, St. Philip Benizi (1233–85). The eremitical life was established on Monte Senario about 1410 and later developed into a distinct congregation. Soon after this a vigorous reform movement began in northern Italy; in 1614 a far-reaching Germanic reform was begun at Innsbruck by the Venerable Anna Juliana, archduchess of Austria.

The characteristics of the order can be summed up in the two main religious currents that preceded its birth, the monastic and eremitical, while to these the founders added the life of a friar under the patronage of St. Mary, the Mother of God. The service of the order to the church is carried out both within the monastery and by apostolic works on six continents. There are also sisters who share in the active works of the order and nuns devoted entirely to prayer within the monastic enclosure. The friars' garb consists of black tunic, scapular, and cowl, with a rosary of the seven sorrows of Mary. The general motherhouse is at Rome.

SERVIUS (fl. *c.* A.D. 400), whose other names sometimes appear in manuscripts as Marius or Maurus and Honoratus, was a Latin grammarian, commentator, and teacher and author of a valuable commentary on Virgil. As an *adulescens* he was one of the speakers in the *Saturnalia* of Ambrosius Theodosius Macrobius (*q.v.*) and at least the greater part of his life was spent in Rome.

His commentary on Virgil is extant in two versions, a longer and a shorter. The longer and anonymous version, first printed in 1600 in an edition by Pierre Daniel, consists of Servius' own work—somewhat altered—in which he sought to meet the needs of schools and paid special, but not exclusive, attention to grammatical and stylistic points. With it are incorporated some valuable additions, in the main from a commentary—perhaps those parts of the commentary by Aelius Donatus which were not used by Servius—which mostly concern Virgil's rhetoric, mythology, and subject matter. These are a precious source of knowledge about Roman antiquities. They presuppose that Virgil had an exact knowledge of ancient Roman customs and institutions.

Servius was a pagan, convinced that Virgil represented the highest truth. He was a learned man and a capable verbal expositor; but he was not a literary critic. His work is interesting as an example of 4th-century exegesis for schools.

An *Explanatio in artem Donati* and three unimportant works—*De centum metris, De finalibus* and *De metris Horatii*—also go under Servius' name.

SERVIUS TULLIUS, sixth king of Rome (traditionally 578–534 B.C.). In legend he was slave-born in the household of Tarquinius Priscus. He married Tarquin's daughter and succeeded him by the contrivance of his mother-in-law, Tanaquil, who was prophetic and foresaw his greatness (this story seems obviously designed to account for his name, which suggests a servile origin). He was eventually killed by his daughter and her husband Tarquinius Superbus. He is undoubtedly a historical personage, but authorities are divided on his nationality. According to one tradition he is Etruscan, a logical inference from his reign between the two Etruscan Tarquins, Priscus and Superbus. This is reinforced by another legend (late, however) identifying him with the Etruscan Mastarna who is associated in a 4th-century B.C. wall painting from Vulci with the killing of a Roman Tarquin. There is perhaps even stronger evidence, however, in the events of his career to suggest he was Latin. Many of these are fictitious, but several can be accepted as historically accurate. He founded the earliest and most important shrine of Diana, a Latin deity, on the Aventine Hill, and to his reign is assigned a crucial treaty between Rome and the Latin League. These both seem authenticated by the preservation in this temple of the text of the treaty down to the Augustan era.

Servius is also traditionally credited with a revision of the constitution which reclassified the population. The significance of this "Servian Constitution" is much disputed, but it is probably a reading back into the legendary past of reforms which were not effected until a much later date. The Servian Wall around the city of Rome ascribed to this period is likewise much later, dating from the 4th century B.C.

SERVOMECHANISM, a device which tends to position an object in accordance with the command given by an arbitrarily varying position indicator capable of supplying only a small amount of power. The operation of a servomechanism is dependent upon the difference between the actual position of the object and the desired position. The servomechanism acts to reduce this difference, called the error, despite disturbing influences. A common example is the automatic pilot in which a signal indicating the actual direction and height of the aircraft is compared with a signal indicating the desired direction and height; any difference actuates ailerons and rudder to position the aircraft onto the desired course.

Most servomechanisms do not rely on human beings to carry out their function. A simple servomechanism in which a human being is involved, however, serves to illustrate all the essential elements. When an operator drives a car he becomes part of a servomechanism whose object is to keep the actual path of the automobile following the desired path, the road. As the road changes direction and the desired path of the car changes, the operator senses any difference between the actual path of the car and the desired path. His eyes detect any existing errors, his brain signals his muscles to act and by means of the steering mechanism of the automobile he corrects the actual path to coincide with the desired path. He is able to do this despite disturb-

ing influences in the form of wind or ruts that might try to force the car's direction from the desired path. Even this simple system does not always respond in the same way. For example, drivers have different reaction rates in the detection of errors and apply different magnitudes of correction for the same deviation from the desired path. Automobiles differ in their responses, too, depending upon the steering ratio and size of the load in the car. Actual malfunction of the apparatus, such as that caused by backlash in the steering mechanism or by soft tires, influences the accuracy with which the path is maintained. These analogies also find their counterparts in completely automatic systems.

The need for servomechanisms arises because man is limited in his ability to perceive errors swiftly and precisely enough, to use his muscles to correct them fast enough and to exert enough power to control the enormous masses often involved. Servomechanisms are also used to relieve man of the drudgery of many tasks; they operate tirelessly and, when functioning properly, with great accuracy and smoothness. They are capable of amplifying signals of no more power than the light from a star to the hundreds of horsepower necessary to control large masses.

Applications.—There are many practical applications of servomechanisms: one is the automatic pilot mentioned earlier, another is in the field of machine tools, particularly those used to duplicate the contours of a piece with rounded surfaces of different radii, such as an aircraft propeller. In this application, the master pattern is clamped beside the piece of raw metal from which a replica is to be made. The servomechanism positions a metal-cutting tool in accordance with the movement of a stylus that is passed over every part of the surface of the master pattern while the tool cuts away unnecessary metal. The master pattern can be made of some material more easily worked by hand tools than the metal from which the final replica is made.

Many applications of servomechanisms involve military devices. Numerous interconnected servomechanisms are utilized in tracking and firing on an enemy airplane that is invisible to observers at a missile emplacement below. A radar antenna is pointed toward the airplane guided by servomechanisms that detect any slight angular difference between the direction the antenna is pointing and the location of the airplane. Given the location and rate of travel of the aircraft, as shown by the angular speed of the radar antenna, automatic computers can predict the probable path of the aircraft and the proper direction for a missile to be fired to intercept this path; other servomechanisms are then used to position the missile launcher properly. All of this is accomplished without any human intervention.

Automatic Feedback Control.—Servomechanism systems or follow-ups, as they are sometimes called, are important tools in the field of engineering known as automatic feedback control or automatic regulation, serving that portion of the field concerned with controlling the position of an object. The systems have wide industrial uses in such tasks as the control of pressure, flow, liquid level, temperature, and many combinations of these in such industries as oil refining, chemical production and food processing.

Automatic feedback control of the more general sort is older in application; indeed, nature has utilized this phenomenon for the control of many functions of the human body. There is a body-temperature regulator; if there were none, the heat produced in 20 min. of muscular effort would cause the albuminous substances in the blood to harden like the white of a hard-boiled egg. At the slightest rise in body temperature, a series of operations goes into effect: the blood vessels dilate and constrict, diverting blood from the internal organs to the surface; blood volume is increased by dilution with fluid drawn from the tissues, thus producing further cooling; sweat glands produce more perspiration; the flow of blood is increased by more rapid pumping of the heart; and the respiratory rate increases to provide more air to the lungs. In addition, if there were no acidity regulator, the lactic acid produced from such muscular effort would upset the acidity of the blood and cause convulsions and death.

Common feedback control devices include the household thermostat, the speed governor on a household mixer, the temperature control in an electric iron and the pressure regulator in a household pressure cooker. Such devices are unified with servomechanisms by a common theory of operation even though they are concerned with the control of temperature or pressure rather than position. They all involve a closed loop of causal action; *i.e.*, the existence of an error causes the device to attempt a correction of the error. The result of this correction changes the error which in turn causes the device to act again. In actual operation these actions take place continuously and instantaneously. The only reason an error exists at all in a servomechanism is because the desired state or output is constantly changing and external influences are also tending to change the actual state of the object.

The principal measure of the excellence of performance of a servomechanism is the accuracy with which the output is positioned relative to its desired value; in other words, whether or not the error is within tolerable bounds. A consequence of this requirement is that the system be stable; *i.e.*, that the output not oscillate or "hunt" about its desired value.

These requirements can be illustrated by the example of a large ship at sea being steered in accordance with a desired heading. Assume first that a helmsman is in control whose job is to detect the difference between the actual heading of the ship, as given by a compass reading, and the desired heading, as given by orders from the captain. He is required to do this despite the disturbing influences of wind and waves, the hydrodynamic effect of the water through which the ship is passing and ocean currents that might tend to force the ship from the desired direction. If an error exists, the helmsman rotates his wheel; the ship slowly responds in accordance with his signal, reducing the error. A considerable amount of turning momentum is built up in this process and an inexperienced helmsman may not realize this until the error is reducing rapidly to almost zero. Seeing that the ship is turning through the proper heading, he applies the opposite rudder in an attempt to once again bring the error to zero. The ship slowly responds to his signal again and eventually builds up a considerable amount of momentum to rotate it in the correct direction and reduce the error. The course of the ship might again overshoot its desired course and this process could continue indefinitely unless the skill of the helmsman improved.

Helmsmen learn with experience, however, that small errors should be met with small corrections. They also learn that after they have introduced a rudder angle to correct an error, they must anticipate the tendency to overshoot and bring the rudder back to zero more swiftly than otherwise, or even apply a reverse rudder as the error reduces. By skillful application of this proportionate control and realization of the fact that the error is rapidly reducing and that something must be done before it reaches zero, a pilot may become very skilled, the oscillations practically nonexistent and the accuracy of the heading maintained despite external influences. An automatic pilot, which supplants the human pilot in a ship or aircraft, has the same problems and if properly designed can apply corrections in the same manner as the skillful human pilot.

Basic Components.—Every servomechanism consists of certain basic elements that combine to perform the functions described in the given examples. First of all, there must be an error detector, some device for detecting and measuring the difference between the desired position of an airplane, for example, and its actual position. There must also be a means of controlling the source of power, involving some method of amplifying what may be a tiny signal from the error detector to sufficient power to operate the next element in the chain, the prime mover. In the case of the airplane, the prime mover might be an electrical hydraulic system acting on ailerons and rudder to correct the position of the airplane and bring it into coincidence with the desired position. There must also be some means of modifying the performance of these devices in order to achieve the desired stability and accuracy.

These, then, are the essential elements of any servomechanism. When a human agency is involved, the methods of detection of the error are often the eyes and the brain. A man might also provide some or all of the muscular power needed to move the object to its desired position. His skill, experience and the fine

ness and swiftness with which he can move his hands cause him to supply corrections of the proper amount with proper anticipation in order to prevent oscillations. He may thus achieve the desired performance of stability and accuracy.

In the design of inanimate servomechanisms, components are carefully chosen for their desired application. The error is often detected in electrical form by means of potentiometers or rheostats which can give a voltage signal proportional to the angular difference between their shaft positions. In the case of the automatic pilot aboard ship, the shaft of one of the potentiometers is connected to the ship's compass, the shaft of the other is attached to a dial upon which the desired course can be indicated. The difference between these angular positions of the two shafts appears as an electrical voltage that can be used to control the rudder. Other error-detecting devices rely on magnetic coupling of their parts to produce a voltage proportional to the error.

The means used to control the source of power involves amplification which can be electrical, electronic, hydraulic, mechanical or a combination of these.

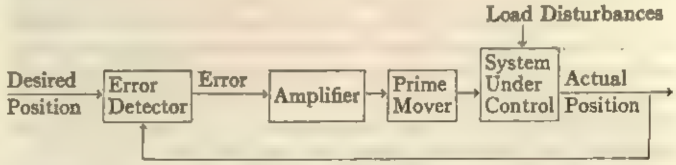
A prime mover supplies the muscles which actually move the object to its desired position. If this object has a small mass, such as in computers or other type instrument applications, the power of the prime mover need not be large, and is commonly a small electric motor. On the other hand, if the mass involved is several hundred tons, a large electric motor or large hydraulic pump and motor might be used to position the mass.

To make the servomechanism satisfactorily stable, some kind of process that damps any oscillations must be employed. Damping can be achieved electrically by the introduction of networks in the electronic amplifier or by feeding back into the amplifier a signal from a generator or other device that measures the speed of the object being positioned. Knowing the speed with which an object is approaching the zero error position, the amplifier can combine this information with a measurement of the size of the error and achieve stability in the same manner that the skilled helmsman anticipates the motion of the ship in response to his correcting forces.

Performance in a servomechanism is measured by comparing its accuracy to the accuracy required of the system in which it is to be used. Some systems do not require a high order of accuracy and may be required to follow desired angular motions only within an accuracy of 1°. However, other applications such as the positioning of optical mirrors in gunfire control may require the mirrors to be aimed within one minute of arc, $\frac{1}{21,600}$ part of a circle. For such an application, the components of the system have strict requirements.

For one thing, the error detector must be extremely accurate because the servomechanism is relying upon the error detector as its only means of knowing of an existing error in the position of the mirrors. The amplifier must likewise be capable of amplifying very minute error signals without distortion. These signals are very small because the servomechanism, if it is performing its job well, has a very small error and hence the signal from the error detector which is proportional to the error is also small. The error signals must be amplified many thousand-fold to be large enough to control a source of power such as an electric motor; the motor must be extremely responsive to signals from the amplifier. Some of the gearing used to connect the high-speed shaft of the motor to the relatively low-speed shaft of the mirror must be of a high order of accuracy so as not to introduce error into the system. Ingenious stabilizing devices must be used if the mirror is to follow its desired angle accurately and without oscillation.

Analysis and Design.—The analysis and design of servomechanisms is often carried out by the use of a block diagram which allows the designer to think more readily in terms of operational characteristics of the system rather than of the wires, vacuum tubes, hydraulic components and other elements involved in it. The block diagram is a graphical representation of the flow of information and the functions performed in the system. The designer can draw the block diagram by studying the operation of each element in order to recognize its function and by analyzing the relationship of the elements to learn how the information flows between them.



Block diagrams are also useful in learning about the fundamentals of servomechanisms. In the accompanying diagram, there are two bits of information of concern: the desired position of the object under control and its actual position. These two kinds of information flow into the error detector whose function is to measure their difference and convert it into a usable form. The signal emanating from the error detector is the error; this is fed into the amplifier and then to the prime mover to effect the proper position of the system under control.

From such a block diagram, it is easy to see the closed loop of causal action in which continuous correction is taking place to reduce the error. It is also seen that any modification of the characteristics of any element in the chain can cause modification of the operation of the entire system. More complicated servomechanisms might be represented by block diagrams having many interconnected loops in which information is fed from various portions of the system to other elements.

In addition to experimental techniques, a number of mathematical methods are used to analyze and design servomechanisms. The most commonly employed are the applications of differential equations and the use of operational calculus and frequency-response studies. While mathematics does not give the final answer and adjustments must always be made experimentally, the use of mathematical analysis can greatly shorten the time required to design a servomechanism and indicate the characteristics of components necessary to achieve the required accuracy.

To solve a problem in servomechanism design or analysis, simultaneous differential equations are written relating the various signals in the servomechanism loop. These can then be solved by any of the standard techniques. Often the servomechanism is a linear one or can be considered so for the purpose of analysis. Under these conditions, the solution of the differential equations involves the elementary techniques for solving linear differential equations with constant coefficients (*see* DIFFERENTIAL EQUATIONS, ORDINARY).

A more flexible approach employs the use of operational calculus, the most popular form of which is the Laplace transformation. This enables derivatives, integrals and trigonometric functions to be expressed algebraically in terms of functions of a complex variable. Such a technique permits the dynamics of elements of a servomechanism to be described in terms of algebraic quantities called transfer functions. The characteristics of the whole system are, therefore, simply the combination of the transfer functions of each of the various elements. The designer can then consider the characteristics of each element separately and how each affects the performance of the entire servomechanism loop.

The most flexible technique of design analysis is the use of frequency-response studies. In such a method of analysis, a study is made of the response of each element of the system to sinusoidal signals whose frequencies vary from zero to infinity. When the response to these signals is known, the performance of the servomechanism can be predicted for any type of variation of the desired position or load disturbances after the methods of Fourier. The use of this method of analysis permits the servomechanism designer to utilize the entire field of functions of a complex variable which enables the stability and accuracy of the system to be predicted and the characteristics of any necessary corrective networks to be set forth.

In addition to the problem of performance of servomechanisms, there are other requirements which are of concern to the user. These include the expected life of the apparatus, its serviceability, its reliability under all operating conditions, the workmanship of

its manufacture, restrictions on materials that can be used and economic considerations. There might be other requirements as well concerning the weight, size and resistance to shock and vibration of the servomechanism. Other constraints on the designer are the type of electrical power available, its voltage and frequency variations and the temperature and atmospheric conditions surrounding the servomechanism. All these factors, together with the mathematical considerations given above, give some hint of the complexity of servomechanisms and their design.

See also AUTOMATION; INFORMATION THEORY. (W. R. AH.)

SESAME (BENNE) was one of the first oilseeds grown by man. It probably originated in eastern Africa and later spread to most of the tropical, subtropical, and southern temperate zone areas of the world. Technically *Sesamum indicum*, sesame is an

BY COURTESY OF U.S. DEPARTMENT OF AGRICULTURE

SESAME (SESAMUM INDICUM): (LEFT) GROWING PLANTS AND (RIGHT) PODS AND SEEDS

erect annual plant of many types and varieties. Depending to some degree on the conditions of growth, varieties grow from two to ten feet tall with growth cycles of two to six months; some have branches, others none. One to three attractive flowers (and seed capsules) are borne in the leaf axils. Flowering begins as early as six weeks after planting, continuing until maturity. The white or black seed contains from 45 to 63% edible oil and from 16 to 32% protein. The oil is noted for its stability (resistance to oxidative rancidity). The meal, or oil cake, remaining after oil extraction is a rich source of protein (especially the amino acid methionine), calcium, phosphorus, and the vitamin niacin; it is used chiefly as a cattle feed.

Sesame is used as a salad or cooking oil, in shortening and margarine, and as a carrier for fat-soluble pharmaceuticals. The whole seed is used in a wide variety of confections and as a garnish for bakery goods.

In normal sesame, capsules open when dry, allowing the seed to scatter, making necessary considerable hand labour in harvest to prevent seed loss. Discovery of nonscattering mutant in 1943 led to the possibility of complete mechanized production of this crop. (M. L. K.)

SESOSTRIS, the Greek name of a legendary king of Egypt. According to Greek traditions preserved by Herodotus, Diodorus Siculus (who calls him Sesoosis), and Strabo, he conquered the whole of Asia, divided Egypt into administrative districts or nomes, was a great lawgiver, and introduced a system of caste and the worship of Sarapis. Manetho names him among the kings of the 12th dynasty. During this prosperous period of Egypt's Middle Kingdom, three kings in fact bore the name, the Egyptian form of which was Senusret or Senwosre (formerly read Usertesen).

SESOSTRIS (Senusret) I (reigned 1971–1928 B.C.) inaugurated a policy of conquest in Nubia and extended the frontier to the Second Cataract of the Nile; he engaged in considerable commercial and diplomatic activity in western Asia, opened new mines and quarries, and began to exploit the resources of the Fayyum. He erected monuments to the gods in sites all over Egypt.

SESOSTRIS (Senusret) II (1897–1878 B.C.) is Manetho's Sesostris; little is known of him. The ruins of the town built to house the men working upon his pyramid at Illahun in the Fayyum have produced unique information about the domestic architecture of ancient Egypt and some important legal documents.

SESOSTRIS (Senusret) III (1878–1843 B.C.) was the successor of Sesostris II; under him the dynasty attained the height of its prestige and prosperity. Sesostris III completed the subjugation of Nubia and built border forts at Samnah (Semna), at the southern end of the Second Cataract; he led an expedition into Palestine and subjugated the "sand-dwellers"; it is probable that he reorganized the administration of Egypt, abolishing the excessive power of the regional governors (nomarchs) and centralizing authority under his vizier. In Nubia he was later worshiped as a god.

The memory of this splendid age, in which Egypt's prestige had been higher than ever before, remained associated with the name of its greatest monarchs long after the true scale of their achievement had been forgotten, and the legend of the heroic "Sesostris," embodying also memories of that later and greater age of empire builders, the 18th dynasty, was fostered by a people who, at the hands of the Assyrians and the Persians, had suffered humiliation and defeat. *See* also EGYPT: *History*.

(M. S. DR.)

SESSA AURUNCA, a town of Campania, central Italy, in the province of Caserta, lies on a lava deposit of the extinct Roccamonfina volcano, 33 mi. (53 km.) NNW of Naples. Pop. (1961) 27,941 (commune). The town, built on the site of the ancient Suessa Aurunca, has Roman ruins which include a large cryptoporticus (a private gallery) and a bridge with 21 arches. The 13th-century Romanesque Duomo (cathedral), with the plan of a basilica, has three aisles, a mosaic pavement with geometrical designs, and a paschal candelabrum. The singers' gallery is supported by nine lion-based columns, whose capitals are carved with prophets and sibyls by the sculptor Taddeo da Sessa. Baroque churches are SS. Annunziata, with a cupola, and S. Agostino, with an adjoining monastery. The earliest Latin satirist Gaius Lucilius (*q.v.*) was born there about 180 B.C. One of the town's two schools is a state boarding school. Agriculture is the chief occupation of the inhabitants, and there is trade in cereals, fruit, and wine. The town is near the main Naples-Rome railway and on the Sparanise-Formia branch line.

The ancient Suessa Aurunca was the chief city of the Aurunci and was punished by the Romans for refusing to pay tribute. Later it was made a municipium. During the civil war (88 B.C.) between Marius and Sulla it sided with Sulla. Augustus set up a colony there and changed its name to Colonia Julia Felix Classica. Its subsequent importance has been due only to its rich agricultural land. (M. T. A. N.)

SESSIONS, ROGER HUNTINGTON (1896–), U.S. composer of symphonic and instrumental music who played a leading part in the formation of modern musical taste among his contemporaries, was born in Brooklyn, N.Y., on Dec. 28, 1896. He studied at Harvard University and at the Yale School of Music, and later took composition lessons from Ernest Bloch. He spent several years in Europe, returning to the United States in 1933, though between 1928 and 1931 he had presented in New York, in association with Aaron Copland, an important series of concerts of modern music (the Copland-Sessions Concerts). He taught composition at Princeton University from 1935 to 1945, at the University of California, Berkeley, from 1945 to 1952, and again at Princeton from 1953. In 1965 he was appointed to the staff of the Juilliard School of Music, New York City. His first important work, an orchestral suite from the incidental music which he wrote for Leonid Andreev's play *The Black Maskers* (1923), is marked by rhapsodic eloquence and even flamboyance, and his

remained his most popular score. His five symphonies (1927, 1946, 1957, 1958, 1963) are severe in idiom, using a polyphonic technique and asymmetrical rhythms. Similar qualities mark his two string quartets (1936, 1950), string quintet (1957), two piano sonatas (1930, 1946) and his Chorale Preludes for organ (1925). His one-act opera *The Trial of Lucullus* (1947) and his *Idyll of Theocritus*, for soprano and orchestra (1954), have affinities with the central European expressionist style. His opera *Montezuma* was produced in West Berlin on April 19, 1964. His critical works include *The Musical Experience of Composer, Performer, Listener* (1950) and *Reflections on the Music Life in the United States* (1956). (N. Sy.)

SESTINA, a most elaborate form of verse, employed by the medieval poets of Provence and Italy, and occasionally used by modern poets. The scheme was the invention of the Provençal troubadour, Arnaut Daniel, who wrote many sestinas. Dante, a little later, wrote sestinas in Italian. In the *De vulgari Eloquentia*, Dante admits that he imitated Daniel.

The sestina, in its pure medieval form, consists of six stanzas of six lines each of blank verse: hence the name. The final words of the first stanza appear in varied order in all the others, the order laid down by the Provençals being: *abcdef, faebdc, cfdabe, ecbfad, deacfb, bdfeca.*

After these stanzas followed a *tornada*, or *envoi*, of three lines, in which all the six key words were repeated in the middle and at the end of the lines in the following order: *b-e, d-c, f-a.* Petrarch cultivated a slightly modified sestina, but later the form fell into disuse, until it was revived by the poets of La Pléiade, in particular by Pontus de Tyard. In the 19th century, it was assiduously cultivated by the comte de Gramont, who, between 1830 and 1848, wrote a large number of examples, included in his *Chant du passé* (1854).

A sestina in English was published in 1877 by Edmund Gosse; this was in the style of Daniel. It was subsequently frequently employed by English and American writers, particularly by Swinburne, who composed some beautiful sestinas on the French pattern; of these, that beginning "I saw my soul at rest upon a day" is perhaps the finest specimen in English. Swinburne's astonishing tour de force, "The Complaint of Lisa," is a double sestina of 12 stanzas of 12 lines each. The sestina was cultivated in Germany in the 17th century, particularly by Martin Opitz von Boberfeld and Georg Weckherlin. In the 19th century an attempt was made, not without success, to compose German sestinas in dialogue, or even double sestinas. (G. W. A.; X.)

SÈTE (CETTE), a seaport of southern France in the *département* of Hérault, Languedoc region, and the principal commercial port on the south coast after Marseilles, lies 200 mi. (322 km.) S. by W. of Lyons and 76 mi. (123 km.) S.W. of Avignon by road. Pop. (1962) 35,910. The older part of the town occupies the foot and slope of the isolated Mont St. Clair (574 ft. [175 m.]), on a tongue of land between the Mediterranean and the large lagoon of Thau (29 sq.mi. or 75 sq.km.). This quarter is bounded on the east by the Canal de Sète, which leads from the lagoon to the outer harbour. Between this canal and the Canal Maritime are two islands divided by a wet dock; the two canals are joined at the north by the Canal Latéral. A huge breakwater protects the entrance to the harbour, and a south mole and east jetty enclose the Old basin (the fishing harbour) and the outer harbour. At the outer end of the Canal Maritime are the New and Mediterranean basins, and the oil basin from which refined oil products from Frontignan are exported by pipeline. Damage done during World War II has been repaired. Facilities for the bulk discharge and storage of wine are extensive, with mechanical loading and unloading of wine through 50 pipelines, and Sète is probably the world's foremost wine port. Export and import traffic increased from 1,630,000 tons in 1938 to more than 4,000,000 tons in the early 1960s. There is a fishing industry and shellfish are intensively cultivated in the lagoon. On one island is a marine biological station. Local industries include chemical products, phosphates and cement, and the manufacture of spirits and vermouths. Sète is well served by sea, rail, and road. A sandy bathing beach stretches for about 9 mi. S.W. to Agde. Sète has become a considerable tourist resort, with many festivals including the ancient sport of water jousting.

The port was created in 1666 on the instructions of Colbert, minister of Louis XIV, and laid out according to plans made by Paul Riquet; its development was aided by the opening of the Canal du Midi later in the century. The present form of its name was fixed in 1927. Paul Valéry, the poet, was born and is buried in Sète, and a hall of the municipal museum is named after him.

SETEKH (SUTEKH or SET; Greek SETH), an ancient Egyptian god, patron of the 11th nome or district of Upper Egypt. His name was probably pronounced Suta or Seta in the late period, hence the Greek form. His worship centred at Ombos, the ancient Nubt, near Ballas in Upper Egypt, whose early importance gave Setekh his leading role as the partner and rival of Horus (*q.v.*). The archaic kings of Egypt were thought to be incarnations of both gods, and during the 2nd dynasty Setekh may even have replaced Horus for a time as the paramount royal deity. He was represented as a composite creature with a greyhound's body, long curved snout, and slanting eyes, his square-tipped ears and long forked tail held stiffly erect. Various animals (*e.g.*, dog, pig, donkey, giraffe, okapi, and anteater) have been suggested as prototype of this remarkable monster, whose zoological original had been long forgotten.

The vicissitudes of the cult of Setekh reflect the changing political scene in Egypt. During the rule of the Hyksos, he was worshiped at Avaris in the guise of the Canaanite storm-god Baal. As god of the eastern delta he was the patron of the Ramesside kings, and he appeared in mythological scenes standing at the prow of the barque of the sun-god and stabbing the wicked monster Apophis with his lance. He was the red god, the patron of the deserts and oases and counterpart of his brother Osiris, the god of vegetation. In the late pharaonic period, when the cult of Osiris gained great popularity, Setekh was execrated as his murderer; Horus, son of Osiris, fought with Setekh and avenged his father's death. The worship of Setekh was proscribed and his image effaced from monuments. As the personification of evil, Setekh was depicted in Ptolemaic temples as a hippopotamus or crocodile; the Greeks identified him with the demon Typhon. (M. S. DR.)

SETH (SHETH), one of the sons of Adam and Eve. According to the Priestly source he was the eldest son (Gen. 5:3; *cf.* also I Chron. 1:1 and Luke 3:38). The main tradition of the Yahwist source, on the other hand, makes Cain the firstborn son and Seth the third (Gen. 4:25). Num. 24:17, the Moabites are called "sons of Sheth"; this may be due to confusions with the Sutu of the cuneiform records, a nomad people of the north Syrian desert. Seth is much more prominent in Jewish tradition than in the Old Testament and many fancies gathered around the name. In the Old Testament it is said of him only that he was the father of Enosh and other children.

SETI I (GR. SETHOS) (d. 1304 B.C.) was a warrior pharaoh of the 19th dynasty who reigned over Egypt from 1318 to 1304 B.C. His father, Ramses I, reigned only two years, and it was Seti who was the real founder of the greatness of the Ramessids. In the early years of his reign he led his army northward to restore Egyptian prestige, partly lost during the troubled years of the late 18th dynasty. A punitive campaign in northern Palestine is recorded in the temple at Beth-shan (Beisan; *q.v.*), near the Sea of Galilee, and his campaigns in Syria are depicted in the vigorous reliefs in the temple of Karnak. He fought at least one battle with the Hittite king Muwatallis, and subsequently concluded a peace treaty which may have established the frontier at Kadesh on the Orontes River between Lebanon and Anti-Lebanon.

Seti did much to promote the prosperity of Egypt. He fortified the frontier; opened mines and quarries; dug wells and rebuilt temples and shrines which had fallen into decay or been damaged in the years of the monotheistic heresy under Ikhnaton (*q.v.*); and he continued the work begun by his father on the construction of the great hypostyle hall at Karnak, which is one of the most impressive monuments of Egyptian architecture (*see* THEBES). His greatest memorial is perhaps his mortuary temple at Abydos (*q.v.*) which he dedicated to Osiris and six other deities and deco-

rated with reliefs of great delicacy on which some of the original colour remains. Behind this temple is a curious building thought to be his cenotaph. His tomb is the finest in the Valley of the Tombs of the Kings in western Thebes (*see* THEBES); it was excavated by Giovanni Belzoni in 1817, and the fine alabaster sarcophagus is now in the Soane Museum in London. The king's mummy had been moved in ancient times and was found in the cache of royal mummies at Dayr al Bahri; it is now in Cairo. *See* also EGYPT: *History*. (M. S. DR.)

SÉTIF, chief town of the *département* of the same name in the province of Constantine, Algeria, 69 mi. (111 km.) SE of Bougie (Bejaïa) and about 1 mi. (2 km.) from the left bank of the Bou Sellam Oued, a tributary of the Sahel-Soummam Oued. Pop. (1960) 82,340. The town, laid out in a grid pattern of wide streets, stands at an altitude of 3,596 ft. (1,096 m.) on a fertile plateau largely given over to cereal cultivation. Sétif is connected by road and rail with Constantine, Bougie, and Algiers.

The ancient Sitifis became an important town when the emperor Nerva established a colony of veterans there *c*. A.D. 97. Sitifis became the chief town of the province of Mauretania Sitifensis (created at the end of the 3rd century) and remained so under Byzantine rule. In the military quarter, in the north of the town, are parts of the walls of the great Byzantine fortress. An open-air museum in the Garden of Orléans has statues, bas-reliefs, and inscriptions from Roman Sitifis. In 1959 a rich Roman necropolis was discovered near the centre of the city, between the synagogue and the wall of the citadel. (A. AM.)

SETON, a celebrated Scottish family deriving its name from the Seatown (Seyton) of Tranent in East Lothian. The house of Seton has in Scottish history been remarkable as being perhaps the most outstanding exponent of splendour in art, architecture, and heraldry, and its members have been consistently noted for the charm and "nobleness" of their lives and characters. Family honours have included the earldoms of Winton and Dunfermline; Seton scions became earls of Eglinton through marriage with the Montgomeries; and, through alliance with a Gordon heiress, ancestors of the earls and marquesses of Huntly.

The first recorded ancestor was ALEXANDER DE SEATON, who witnessed a royal charter of about 1150. His son, PHILIP DE SETON, held Setune, Wintune, and Winchelburgh by a charter granted between 1177 and 1185, and Philip's son, ALEXANDER DE SETON (d. *c*. 1245) had confirmation of these lands by a charter dated about 1195. Some three generations later, SIR ALEXANDER DE SETON (d. *c*. 1349), lord of Seton (who, with the chiefs Sir Gilbert Hay and Sir Neil Campbell, pledged support to Robert I, "the Bruce," in the "band" of 1308), contributed to the victory at Bannockburn in 1314, subscribed to the barons' declaration of 1320 to Pope John XXII, which asserted the independence of Scotland, and acquired special fame as the defender of Berwick against the English in 1333. All his four sons fell in the service of Scotland, THOMAS (d. 1333), the eldest, being hanged by Edward III before the walls of Berwick, since his father would not yield the town. SIR JOHN (d. *c*. 1328), the youngest, left a son SIR ALEXANDER (d. *c*. 1346) with whom the direct male line failed, whereupon the succession passed to MARGARET, lady of Seton, apparently the only child of the third son SIR ALEXANDER (d. 1332), who was killed while trying to repulse the landing of Edward Balliol. Margaret was romantically abducted in 1347 by Alan de Wyntoun, traditionally a cadet of the Seton line, who had Winton as appanage. This exploit, and their marriage, created a family feud in Lothian, and Alan went on crusade to the Holy Land where he died.

Their son, SIR WILLIAM DE SETON (d. *c*. 1409), lord of Seton and Tranent, carried on his mother's line as chief of the name of Seton, and with Winton recovered, restored the power of the family. From his second son, ALEXANDER, who married Elizabeth, heiress of the Gordon chiefs, descended the earls and marquesses of Huntly (chiefs of clan Gordon, George, the 2nd earl, having taken that surname), and also the Setons of Meldrum, Pitmedden, Mounie, and others. Sir William's eldest son, SIR JOHN SETON (d. *c*. 1433) of that ilk, the next chief, and his son SIR WILLIAM (who was killed at Verneuil in 1424), were famous in chivalry. SIR GEORGE DE SETON (d. *c*. 1479), the only son of Sir William, who succeeded before 1434, was created a lord of Parliament, as Lord Seton, before 1445 (a dignity sometimes stated to have begun in his grandfather). "Ane grit hous haldar, and all gevin to nobilnes," he established the family as Scotland's patrons of splendour, made their palace of Seton the most magnificent seat in Scotland, and built the choir of the parish church of Seton, which became a collegiate church in 1493.

Sir George's grandson and heir, GEORGE (d. *c*. 1508), 2nd Lord Seton, also a patron of arts and letters, bought a warship, the "Eagle," from James IV, and kept her manned at sea to harry the Flemish traders. He was succeeded by his son GEORGE (d. 1513), 3rd Lord Seton, who fell at Flodden and whose widow Janet, eldest daughter of the 1st earl of Bothwell, built Niddrie Castle, West Lothian, and the convent of St. Catherine of Siena, near Edinburgh, during the minority of her son GEORGE (d. 1549), 4th Lord Seton, in whose time the palace of Seton was burned by the English (1544). JOHN, his second son, founded the house of Seton of Carriston, in Fife, while MARIE, the youngest daughter, is the most celebrated of the four "Maries" attendant on Mary Stuart, queen of Scots. George's eldest son, GEORGE (1531–85), 5th Lord Seton, was the queen's most trusted supporter and under him the family reached the height of its fame. In June 1567 Mary and the earl of Bothwell visited Seton, which had been restored and enlarged, and after her escape in May 1568 from Lochleven Castle (to which Marie Seton contributed), Mary went to Niddrie Castle. George's fourth son ALEXANDER (1555–1622), created Lord Fyvie (1598) and 1st earl of Dunfermline (1605), was lord president of Scotland from 1593 to 1605 and chancellor from 1605 to his death. He was one of the most upright and distinguished judges of his time and the patron-architect of perhaps the greatest period in Scottish domestic architecture: Seton Palace, Winton House in Midlothian, Fyvie Castle in Aberdeenshire, Pinkie House in Midlothian, and Muchalls Castle in Kincardineshire were developed or completed by him or under his influence. His line expired with his junior grandson, JAMES (d. 1694), 4th earl of Dunfermline, a Jacobite attainted in 1690.

The 5th Lord Seton's second son, ROBERT (*c*. 1552–1603), 6th Lord Seton, was created earl of Winton (Nov. 1600). By his wife Lady Margaret Montgomerie, daughter of Hugh, 3rd earl of Eglinton, he had a large family, of whom his third son SIR ALEXANDER (1588–1661) of Foulstruther took the name Montgomerie and under a family resettlement became 6th earl of Eglinton. GEORGE (1584–1650), 8th Lord Seton and 3rd earl of Winton, the second son of the 6th lord, completed Seton Palace and in 1620 built Winton House. Of his large family his fourth son ALEXANDER (1620–91) became Viscount Kingston in 1651 and his tenth son JOHN (1639–1686) was created a baronet in 1664, being styled "of Garleston." GEORGE (1642–1704), 9th Lord Seton and 4th earl of Winton, the eldest grandson of the 3rd earl, led a regiment of his vassals in 1679 to Bothwell Bridge, Lanarkshire, where he assisted the royalist troops under the duke of Monmouth to defeat the Covenanters. His son GEORGE (*c*. 1678–1749), 10th Lord Seton and 5th earl of Winton, was attainted for joining the Jacobite rising in 1715 and forfeited his estates in 1716. Seton Palace was subsequently demolished. SIR GEORGE SETON (*c*. 1685–1769), of Garleston, 3rd bart., the grandson of the 1st bart., renounced his own title on the death of the 5th earl in 1749 and assumed the forfeited dignity of the earldom of Winton, but the title was never confirmed. He died unmarried in 1769.

Since 1749 the chiefship of the name of Seton has been dormant. It has been suggested that the lordship of Seton passes in the female line but no claim to this or reversal of the attainder has been formally made. A creation for Archibald William, 13th earl of Eglinton, chief of the Montgomeries, of an earldom of Winton on June 17, 1859, did nothing for the "name of Seton." Two Seton baronetcies still survive: Seton of Pitmedden, conferred in 1684 on SIR ALEXANDER SETON (d. 1719), a distinguished judge and cadet of Seton of Meldrum, of which the present holder is Sir ROBERT JAMES SETON (1926–), 11th bart; and Seton of Abercorn, conferred in 1663 on SIR WALTER SETON (d. 1692), descending from Seton of Touch, hereditary squire of the body of the kings of Scots and under an entail, heritable armourbearers

The present holder is SIR BRUCE LOVAT SETON (1909–), 11th bart.

See Sir Richard Maitland, *The Historie and Chronicle of the Hous of Seytoun,* continued by Alexander, Viscount Kingston (1829); G. Seton, *A History of the Family of Seton,* 2 vol. (1896). (T. I.)

SETON, ELIZABETH ANN (née BAYLEY) (1774–1821), foundress of the American Sisters of Charity, was born in New York City on Aug. 28, 1774. Her concern for the sick and poor early merited her the title of "a Protestant Sister of Charity." In 1794 she married William Seton who died in 1803 in Italy, where the family had gone for reasons of health. Left with five children, destitute in a foreign land, Mrs. Seton turned to the Filicchi family, old acquaintances, whose devotion was to eventually lead her into the Roman Catholic Church. She returned to the United States and after a great spiritual struggle was received into the Catholic Church in 1805. At the invitation of Louis G. B. Dubourg, she opened a grade school in Baltimore in 1809. Soon several young women were placed under her care; this led to the taking of simple vows as the "Sisters of St. Joseph." The community decided to take as its model the Sisters of Charity of St. Vincent de Paul, but it was not until 1812, after the community moved to Emmitsburg, Md., that the constitution and rules were formally adopted. Elizabeth, now known as Mother Seton, was named first superior but was allowed to remain legal guardian of her children. Mother Seton has been called the first of the American Catholic sister-school nuns, and the mother of the parochial school system of the United States, although hers was not the first Catholic grade school. She died Jan. 4, 1821. On March 17, 1963, she became the first native-born American to be declared blessed; her cause for canonization was introduced in 1965.

SET THEORY (THEORY OF AGGREGATES). Set theory was created, almost without forerunners and against the opposition of most leading mathematicians of the time, between 1874 and 1897 by Georg Cantor (1845–1918). Since the beginning of the 20th century it has developed enormously and gained ever-increasing recognition and importance in both mathematics and logic, being applied in almost all fields of mathematics in view of the set-theoretical analysis of general mathematical concepts such as number, correspondence, function, order, etc. This article deals with the theory of abstract sets; *i.e.,* sets without discrimination as to the nature of their members.

Two principal attempts were made to define the concept of set: (1) as an arbitrary collection of "definite and distinct" objects (Cantor); and (2) by "comprehension" of the objects satisfying a given property. Both proved to be too general and led to contradictions, the antinomies of set theory. Although Bertrand Russell showed that the antinomies were of a logical or semantical rather than mathematical nature, a new foundation became imperative. The main direction taken involved restricting the extent of sets, either axiomatically or by silent limitation. The term "class" is used for extremely comprehensive sets, but, to avoid confusion with the logical concept of class, it will not be used here.

Fundamental Concepts.—The fundamental relation of set theory is membership: a is a member of the set s; in symbols, $a\epsilon s$. For instance, 2 is the only member of the set of even prime numbers; 1,2,3, . . . are among the (infinitely many) members of the set of positive integers. In principle it is sufficient for the needs of mathematics to restrict the members of sets to sets only, because numbers, functions, points, etc., may also be conceived as sets (see *Cartesian Product; Functions as Sets,* below). The principle of extensionality states that sets which have the same members are considered equal; hence the set s with the members $a,b,c,$ . . . may be denoted by $s = \{a,b,c, \ldots\}$. It is then presupposed that with respect to every object x, it shall be definite whether $x\epsilon s$ or not—which, however, need not be decided generally.

Other important concepts are subset, equivalence and order. In principle they can be reduced to the membership relation, but usually this is done for the subset relation only: s is a subset of t ($s \subset t$) if every member of s is also a member of t. Hence $t \subset t$ for every set t. If t has at least one member which does not belong to s, s is called a proper subset. To avoid the confusion prevailing up to the end of the 19th century, mathematicians say that a set contains its members, but comprises (includes) its subsets. Usually a subset of s is defined by a property P which is meaningful for the members of s, namely, as the set of those $x\epsilon s$ which satisfy P. For instance, from the set I of all positive integers and the property "prime" there is obtained the set of all prime numbers, which is a subset of I. If no member of s has the property, there must be admitted a set which contains no member, the empty set or null set ϕ.

If there exists a one-to-one correspondence between the members of s and those of t, s is called equivalent to t, in symbols $s \sim t$; then also $t \sim s$, and $s \sim t$, $t \sim u$ together imply $s \sim u$ (transitivity). A set D which is equivalent to the set $I = \{1,2, \ldots ,k, \ldots\}$ of all positive integers is called denumerable (or countable); denoting by d_k the member of D which corresponds to the integer k, D can be written in the form

$$D = \{d_1,d_2, \cdots d_k, \cdots\}$$

The set of all positive integers I as such is a plain set, but it becomes an ordered set when a succession (order) of its members is introduced, subject to the conditions that for any two different members one and only one precedes the other and that this order relation is also transitive. Possible orders of I are, for instance, (1,2,3, . . .), (. . . ,3,2,1), (1,4,7, . . . 2,5,8, . . . 3,6,9, . . .). The parentheses indicate that the order has to be observed. An ordered set is said to be well-ordered if every (ordered and nonempty) subset has a first member. Accordingly, among the ordered sets above, the first and the third are well-ordered but not the second, because the subset of all odd integers, as well as the set itself, has no first member.

If between the members of the ordered sets m and n there exists a one-to-one correspondence such that if a precedes b in m, also the image of a precedes the image of b in n, m and n are called similar ($m \simeq n$). None of the above ordered sets is similar to another, although, conceived as plain sets, they are equivalent and even equal. Yet, for instance, $(1,2,3, \ldots) \simeq (2,4,6, \ldots)$.

Comparability: Transfinite Induction.—The enormous importance of the well-ordered sets, both for set theory itself and for its applications, lies in the comparability of their ordinal and cardinal numbers and in the availability of transfinite induction.

Equivalent sets are said to have the same cardinal (number), and similar ordered sets are said to have the same order type. The order type of a well-ordered set is called an ordinal (number). For finite sets, the three notions essentially coincide. Comparing (ordering) cardinals according to their magnitude causes great difficulties, and comparing order types is in general altogether impossible. In contrast, ordinals and even the cardinals of well-ordered sets can be compared, and one shown to be less than the other. The well-ordering theorem, one of the most important and most discussed theorems of modern mathematics (E. Zermelo, 1904), states that for any set there exists a well-ordered set with the same members; accordingly, the cardinals of plain sets are also comparable.

For well-ordered sets a far-reaching generalization of ordinary mathematical induction becomes possible. If a statement involving the members of a well-ordered set W is true for the first member of W, and also true for any member w if true for all members that precede w, then the statement is true for all members of W. This theorem of proving by transfinite induction is almost trivial; far more profound is the fact that by this induction there can also be defined, for instance, the arithmetical operations between ordinals.

Finite and Infinite Sets.—The distinction between finite and infinite sets is fundamental. Dozens of definitions are in existence, among them many which differ in principle. To show the difference it is sufficient to mention the following two definitions:

1. A set is called inductive if there exists a positive integer n such that the set contains just n members (the null set is also inductive); otherwise the set is noninductive.

2. A set is called reflexive if it is equivalent to a proper subset; otherwise it is nonreflexive. Hence the set I of all positive integers is both noninductive and reflexive; the latter fact follows, for instance, from the correspondence

$$\begin{array}{ccccccc} 1 & 2 & 3 & \cdots & n-1 & n & \cdots \\ \updownarrow & \updownarrow & \updownarrow & & \updownarrow & \updownarrow & \\ 2 & 3 & 4 & \cdots & n & n+1 & \cdots \end{array}$$

which shows that I is equivalent to the subset obtained by dropping the member 1. It is also equivalent to the subset of all odd, even or prime numbers.

It seems as if "noninductive" and "reflexive" were the same property, namely, infinite; and that inductive and nonreflexive were another property, finite. Only in the first decade of the 20th century was it discovered that the equivalence between the definitions mentioned, as well as others, depends on a new principle of purely existential character, the principle (axiom) of choice or "multiplicative principle," which had not before been formulated and even in the 1960s is not yet generally accepted in mathematics and logic. Russell's formulation (1906) states: If S is a set of nonempty sets such that any two of these sets have no common member, then there exists a set which contains a single member out of each member of S. This principle is indispensable for many other purposes both inside and outside set theory: in the former, for the arithmetic of cardinals and order types, and for the well-ordering theorem, for whose proof the principle was explicitly introduced. By means of the multiplicative principle it can be proved that every noninductive set comprises a denumerable subset, and hence that every such set is reflexive. The equivalence between other definitions of finiteness and infinity can also be proved.

The virtual, though not conceptual, coincidence between cardinal and ordinal numbers of finite sets derives from the following theorem, which is proved for inductive sets by mathematical induction: By arranging the members of a finite set in any two different ways two ordered sets are obtained which, although different, are similar; *i.e.*, follow identical schemes of order: first, second, . . . , nth, with the same n terminating. The above examples of (essentially) different orders of the set I show that this theorem does not hold for infinite sets; in fact, to an infinite cardinal belong infinitely many different order types and ordinal numbers.

Boolean Algebra.—Prior to the invention of set theory, Boolean operations had been introduced and applied by G. Boole (1815–64) and others; set theory increased the applications of these operations. Two major and one minor operations between sets are fundamental. The union of two or more (or infinitely many) sets $s_1, s_2, \ldots$ is the set of those members which are contained in at least one set s_n, and is denoted by $s_1 \cup s_2 \ldots$. Corresponding to this operation is the operation of intersection, which yields the set $s_1 \cap s_2 \ldots$ of the members contained in each of the sets s_n. Of minor importance is the difference $t - s$, which is essential only in the case $s \subset t$; then $t - s$ is the set of the members of t which are not contained in s. Here again the significance of the null set becomes manifest; without it the intersection of two sets having no common members, as well as the difference $t - t$, would not exist. In Boolean algebra, but not in general set theory, there is introduced, corresponding to the null set, the "universal set" U, which contains all members considered. The difference $U - s$ is called the complement of s.

Union and intersection are in many respects analogous to sum and product in arithmetic; the operations are commutative (by definition) and associative. The first distributive law,

$$s \cap (t_1 \cup t_2 \cup \cdots) = s \cap t_1 \cup s \cap t_2 \cup \cdots$$

corresponds to the arithmetical law $a(b + c) = ab + ac$; the second distributive law of Boolean algebra, however, viz.,

$$s \cup t_1 \cap t_2 \cap \cdots = (s \cup t_1) \cap (s \cup t_2) \cap \cdots$$

has no parallel in arithmetic, where $a + bc$ in general differs from $(a + b)(a + c)$. The validity of both laws is not accidental but is connected with a law of duality; this latter law may be based on the laws of A. de Morgan, which state that the complement of a union of sets is the intersection of the corresponding complements, and that the complement of an intersection is the union of the complements. From this it is concluded that, A being a set formed from sets $s_1, s_2, \ldots$ by repeated operations of union and intersection, the complement $A' = U - A$ is obtained by replacing the sets s_n by their complements, union by intersection, and intersection by union. Since $A = B$ implies $A' = B'$, any equality resulting from those operations remains true after the replacements have been effected, and if the equality is an identity (*i.e.*, true for any set) the transition to the complements becomes superfluous. For example, from $s \cup s' = U$ follows $s \cap s' = \phi$ and from $s \cup \phi = s$ follows $s \cap U = s$ for any set s; one distributive law follows from the other. From $s \subset s \cup t$ follows that $s \subset t$, $s \cap t = s$, $s \cup t = t$ are equivalent statements, as are $s = t$ and $s \cap t = s \cup t$

Usually the term Boolean algebra is reserved for the abstract theory in which no reference is made to the meaning of union, intersection, complement and subset; a few of the statements mentioned above, and others, are then considered to be the axioms of Boolean algebra.

The significance of Boolean algebra in logic mainly derives from the fact that union corresponds to logical disjunction (in the sense of *vel*, not exclusive), intersection to logical conjunction, complement to negation and the subset relation to (material) implication. For instance, $s = U$ corresponds to "everything is an s," $s = \phi$ to "there is no s," $s \cap t \neq \phi$ to "some s are t," $s \cap s' = \phi$ to the logical law of contradiction and $s \cup s' = U$ to the law of the excluded middle.

The operation of union (but not of intersection) is basic for the arithmetic of cardinals, namely, for their addition: a sum of finitely or infinitely many cardinals is defined as the cardinal of the union of sets (representatives) with the respective cardinals, if no two representatives have common members. To be sure, the sum's independence of the particular representatives rests upon the principle of choice if the sum has infinitely many terms.

Cartesian Product; Functions as Sets.—In addition to union and intersection there are two other operations with sets which have great importance not for Boolean algebra but for the arithmetic of cardinals, and to a lesser degree of order types, and for the applications of set theory to analysis. One is the Cartesian product. If s and t are sets, say without common members, the Cartesian product $s \times t$ is defined as the set of all pairs

$$\{\sigma, \tau\} \text{ with } \sigma \in s \text{ and } \tau \in t$$

For instance, if $s = \{1,2,3\}$, $t = \{4,5\}$, then $s \times t = \{\{1,4\}$, $\{1,5\}, \ldots\ldots, \{3,5\}\}$; *i.e.*, a set with $3 \times 2 = 6$ members. Therefore the product of two cardinals is defined as the cardinal of the Cartesian product of suitable set representatives. The definitions of both Cartesian products and of products of cardinals may be extended to any finite or infinite number of factors.

While it follows from the definition that a Cartesian product, among whose factors the null set occurs, is empty—hence a product of cardinals with the factor zero equals zero—the converse statement, for infinitely many factors, rests on the principle of choice or, more precisely, constitutes this principle. In fact, only by "choosing" one arbitrary member out of each factor set, none of which is empty by assumption, can it be generally ensured that the Cartesian product is not empty. This is the origin of Russell's term "multiplicative principle." Incidentally, Russell illustrated the difference between set formation by (constructive) "comprehension" and by purely existential "choice" by confronting a set of infinitely many pairs of shoes with another of pairs of stockings. To obtain a set that contains a single member of each pair, it suffices in the first case to take the set of all left shoes which is defined constructively; yet the existence of a set containing a single stocking of each pair is guaranteed only by the axiom of choice.

Finally, for the exponentiation of sets or cardinals a generalization of the ordinary concept of function is most appropriate. For functions $s = f(t)$, assume the domain of variability to be an arbitrary set T over which the argument t runs, whereas the func-

tion values s are members of a set S. The insertion set (S/T) shall be defined as the set of all such functions; *i.e.*, of all "insertions" of members of S into T. For instance, simultaneously casting four dice (whose sides show from one to six pips) produces a function $s = f(t)$ with $T = \{1,2,3,4\}$ and $S = \{1,2,3,4,5,6\}$; if two casts are considered equal only on condition that the same die shows the same number of pips, (S/T) contains $6 \cdot 6 \cdot 6 \cdot 6 = 6^4$ members. If T is the set of all positive integers and $S = \{0,1,2, \ldots, 9\}$, every function $f(t)$ may be considered to be a decimal fraction of the form $0 \cdot s_1 s_2 s_3 \ldots$ with values s_t taken from S; hence the insertion set contains all such decimals and its (infinite) cardinal is of the form $10 \cdot 10 \cdot 10 \ldots$, the factors forming a sequence. Thus general powers, with infinite bases and exponents, can be defined and calculated.

The most important case is the so-called power set of a set S; *i.e.*, the set whose members are all subsets of S. It may be conceived as an insertion of the pair $\{1,0\}$ into S, where 1 is related to every $s \epsilon S$ contained in the respective subset and 0 to the members not contained in it. The so-called "theorem of Cantor" (1892) states that the power set of S has, for finite and infinite S, a greater cardinal than S; it constitutes the first step in ascending to ever-increasing infinite cardinals.

Independently of the concept of insertion set, a function can always be regarded as a set; for instance, a single-valued function $y = f(x)$ can be regarded as a set of ordered pairs (x,y) in which different pairs contain different values of x but not necessarily different values of y. Furthermore, integers and even infinite numbers may be regarded as sets; by means of the null set ϕ the integers 0,1,2,3, . . . may respectively be defined as the sets

$$\phi, \{\phi\}, \{\phi,\{\phi\}\}, \{\phi,\{\phi\},\{\phi,\{\phi\}\}\}$$

and generally every ordinal number may be defined as the set of those preceding it. An elaborate theory of numbers in this sense was given by J. von Neumann in 1923. (*See* POINT SET.)

Applications.—The applications of set theory penetrate most branches of mathematics; as N. Bourbaki puts it: "Today it is possible to derive almost all contemporary mathematics from a single source, the Theory of Sets." (*Actualités Scientifiques et Industrielles*, vol. 1212, Paris, 1954.) The applications are most spectacular, through the theory of point sets, in analysis; perhaps the greatest analytical achievements of set theory are the modern theories of measure and integration. In geometry and topology many concepts and problems such as "curve" and "dimension," which had defied the cruder conservative methods, were treated set-theoretically; Cantor solved the riddle of the linear continuum (unsuccessfully attacked from Greek antiquity to the 19th century) in terms of a perfect set; namely, one which densely comprises a denumerable subset. In abstract algebra, the well-ordering theorem and transfinite induction (or an equivalent maximum principle) solve problems such as algebraically closed extensions of a field. The theory of probability owes important achievements to set theory, and there are also applications to the theory of games, to physics and even to chemistry.

The modern development of logic has been closely connected with the development of set theory, and the antinomies have neither checked the development of these sciences nor seriously impaired the agreement of most mathematicians with D. Hilbert's description (1925) of the "paradise created by Cantor from which nobody will ever expel us."

SETTLE, ELKANAH (1648–1724), English playwright and miscellaneous writer, scathingly satirized by Dryden, whose unworthy rival and antagonist he was. Born at Dunstable on Feb. 1, 1648, he went to Westminster school and entered Trinity college, Oxford, in 1666 but left without a degree. His first tragedy, *Cambyses, King of Persia*, was produced in 1666. He was encouraged as Dryden's rival by John Wilmot Rochester, through whose influence Settle's *Empress of Morocco* was twice acted at Whitehall: it also succeeded on the public stage in 1670–71. In the dedication of the printed edition (1673) Settle referred scornfully to other dramatists' effusive dedications, obviously aiming at Dryden who in 1674 cooperated with John Crowne and Thomas Shadwell in an abusive pamphlet condemning the play. Settle replied in kind.

Neglected by the court after 1675, he continued to have his bombastic plays published and performed. However, in 1679 the earl of Shaftesbury engaged him to organize a "pope-burning" pageant and thereafter he wrote copiously for the Whig interest. He published a reply to Dryden's *Absalom and Achitophel* in 1682 and was ridiculed as "Doeg" in the second part of his rival's satire. After Shaftesbury's downfall, he turned Tory, attacked Titus Oates, and even enlisted in James II's army, but soon rejoined the Whigs on the accession of William III.

"Recanting Settle" was appointed the last poet laureate of the city of London in 1691 and devised ten lord mayor's shows during his term of office. Hoping for patronage, he made a practice of composing occasional poems, elaborately bound and now very rare, which he presented to persons of note. He also wrote entertainments for Bartholomew fair, where in his old age, clad in a green leather suit, he is said to have played the dragon in his own droll, *St. George for England*. Pope makes him a type of the dull writer in the *Dunciad*, and puts into his mouth the couplet:

> "Yet lo! in me what authors have to brag on!
> Reduc'd at last to hiss in my own dragon." (iii, 286–87)

He entered the Charterhouse in 1718, and died there on Feb. 12, 1724.

See F. C. Brown, *E. Settle* (1910); *Five Heroic Plays*, ed. by B. Dobrée (1960).

SETTLEMENT, in law, a compromise or agreement between litigants to settle the matters in dispute between them in order to dispose of and conclude their litigation. Generally, when litigants settle their differences, prosecution of the action is simply terminated and the action is withdrawn or dismissed without any judgment being entered. In such a case the settlement itself, as a binding contract between the parties, prevents reinitiation of the litigation. But the parties may, and often do, incorporate the terms of the settlement into a consent judgment, recorded by the court. Such a judgment may afford the same protection against a reopening of the dispute in litigation as is provided by a court judgment at the conclusion of a fully litigated case.

Settlements commonly provide or are construed to allow either party to enforce their terms or at his election ignore them and reopen the underlying dispute should the other party fail to fulfill the terms and conditions agreed upon. Since in modern litigation by far the greater number of suits brought are either withdrawn or settled, the settlement constitutes an important feature of the litigatory process. (*See* JUDGMENTS AND DECREES; PRACTICE AND PROCEDURE.)

The term "settlement" is also applied to a disposition of property to be held in trust (*see* REAL PROPERTY AND CONVEYANCING, LAWS OF; TRUST). (C. E. CL.)

SETTLEMENT, ACT OF, the name given to that act of Parliament passed in June 1701 (12 & 13 Will. III, c. 2) which has since that date regulated the succession to the throne of Great Britain. The settlement made in the Bill of Rights of 1689 extended no further than the children of Queen Mary, the Princess Anne, and William III. Mary died childless in 1694 and William did not remarry. When the last surviving child of Anne, William, duke of Gloucester, died in 1700 the need to provide for the succession after her death became urgent, and it was decided that in default of issue to either William III or Anne, the crown was to pass to the electress Sophia of Hanover, granddaughter of James I, and the heirs of her body, being Protestants.

In addition to settling the succession to the throne, the act further defined the conditions on which it was to be held in clauses designed to come into force on the death of Queen Anne

which were inspired by Tory zeal and characterized as much by suspicion of the foreigner as by suspicion of the executive. Future monarchs were to join in communion with the Church of England and were not to go abroad without the consent of Parliament. Other clauses prohibited the use of English resources in defense of foreign territories without the consent of Parliament and declared that foreigners were not to hold offices or places of trust, to belong to the privy council or to either house of Parliament, or to hold offices of profit under the crown or receive from it pensions or grants of land.

The possibility that members who held places or pensions from the crown might lessen the independence of the House of Commons was to be prevented by excluding them from it. And by stipulating that "all matters . . . properly cognizable in the privy council . . . shall be transacted there" it was hoped that all those who advised the king could be made legally accountable for their advice by being known to belong to an institution known to the law. Another clause protected the independence of the judges by making their appointments *quamdiu se bene gesserint*, dependent on their continued good behaviour, instead of on the sovereign's pleasure (*durante bene placito regis*) as before. They were to be removable only on address of both houses of Parliament. It was also declared that impeachments by Commons in Parliament were not to be interfered with by pardons under the great seal of England.

Just as the Bill of Rights drew attention to actions of James II which were disapproved of, so the Act of Settlement censured by implication many practices of William III. Like it also, it showed how far a reluctance which Tories may once have felt to restrain a divinely appointed monarch was replaced by anxiety to limit the actions of monarchs appointed by Parliament.

So much, indeed, was this the case, that it was thought necessary, for the sake of effective government, to repeal the clause restricting the crown's advisers to privy councilors before it was due to come into effect; and the clause prohibiting placemen and pensioners from the House of Commons was modified by an act of 1707 (6 Anne c. 41 [otherwise cited as c. 7] paragraphs 25–26) which merely obliged members appointed to offices of profit under the crown to seek reelection. Slowly, and somewhat reluctantly, it was being recognized that increasing the importance of the House of Commons in order to limit more stringently the power of the executive might prevent the executive from acting effectively; and also that it might in practice be necessary, when executive action depended upon the support of the legislature, to run the risk that if the executive could not influence the legislature then the legislature might come to control the executive.

See W. C. Costin and J. Steven Watson, *The Law and Working of the Constitution*, vol. i (1952). (Ro. R.)

SETTLEMENT, SOCIAL: *see* Social Settlements.

SETÚBAL, a seaport of Portugal, in the district of the same name, lies 27 mi. (43 km.) SE of Lisbon by road via the Tagus ferry. Pop. (1960) 44,177. The town is situated on the north shore of a deep estuary formed by the Sado, Marateca, and São Martinho rivers. Setúbal exports salt, oranges, and muscatel wine and grapes; it has sardine-curing and boat-building establishments and produces fish manure, cement, fertilizers and canned foods. Under John II (1481–95) Setúbal was a favourite royal residence, but most of the ancient buildings were destroyed by the earthquake of 1755. The most important remaining ones are the Convent of Jesus (Manueline style), the churches of São Julião (Manueline decoration) and Santa Maria da Graça, and the 17th-century castle of São Filipe (now a hotel). In the sand hills on the left bank of the estuary are the ruins of Cetobriga, which was destroyed by a tidal wave in A.D. 412.

Setúbal District, now being industrially developed, occupies the peninsula between the Tagus and Sado estuaries. Pop. (1960) 376,128. Area 1,989 sq.mi. (5,152 sq.km.). It is remarkable for the profuse vegetation on the southern slope of the Serra de Arrábida (1,634 ft. [500 m.]) along the southern coast, including many Mediterranean species, giant oaks, and strawberry trees (*Arbutus unedo*). In the eastern foothills of the Serra is the town of Palmela with a magnificent castle of Moorish origin. The manor of Bacalhoa at Vila Fresca de Azeitão dates from the 15th and 16th centuries and contains beautiful examples of decoration with Portuguese glazed tiles.

SEURAT, GEORGES PIERRE (1859–1891), French painter, the leading figure among a small group of painters known as the Neoimpressionists, was born in Paris on Dec. 2, 1859. From the very start his search for scientific truth and for an applicable formula carried him beyond the limits of academic training; at the same time, he departed from the concept of fleeting pictorial impressions which Claude Monet and his group had developed. The result was a new and valid form of monumentality for easel painting that reinstated a firm structure of composition and re-established the formal value of the subject.

Seurat's artistic career comprised a bare decade and was outwardly uneventful. He began to study drawing when he was 15 and entered the École des Beaux-Arts in 1878 in the class of Henri Lehmann, a pupil of Ingres. Supplementing his formal training with untiring studies in the Louvre and in the libraries, he copied Ingres, Raphael, Holbein and Poussin; he also pored over scientific studies of colour by M. E. Chevreul, O. N. Rood, H. L. F. Helmholtz, D. Sutter and C. Blanc.

After a year of military training at Brest, where he did many studies of people and the sea, Seurat returned to Paris late in 1880. For some time he concentrated mainly on drawing, developing a completely new technique which enabled him to replace line by volume and to create an intricate pattern of light and shade. He also began making small studies in detached strokes of pure colour. In 1883 Seurat began his first major project in painting, "Une Baignade," a large scene with bathers (Tate gallery, London) for which many drawings and studies are extant. When this painting was rejected by the salon of 1884, Seurat, with Paul Signac, H. E. Cross, C. Angrand, A. Dubois-Pillet, M. Luce and, for a short while, Camille Pissarro, helped found the Société des Artistes Indépendants. These painters were also called the Pointillists, Divisionists or Chromatic Luminarists.

In 1884 Seurat began work on his second large composition, "La Grande Jatte" ("A Sunday Afternoon on the Island of la Grande Jatte"). For months the artist was on the island every day sketching. Back in his studio he developed the theme in endless studies, drawings, sketches of sections and complete and carefully

BY COURTESY OF THE BUFFALO FINE ARTS ACADEMY, ALBRIGHT ART GALLERY

Second Study for "Le Chahut," Painted by Seurat in 1889

executed studies of the whole scene. For the final painting (now at the Art Institute of Chicago) Seurat prepared a palette exactly according to Chevreul's colour disk. Four basic colours and their intermediaries were only to be mixed with varying amounts of white before they were applied in a veritable maze of small, carefully separated dots. When shown at the last exhibition of the Impressionists in 1886 "La Grande Jatte" caused a great controversy in which only a few artists, among them Signac and Pissarro, and the poet and art critic Félix Fénéon defended Seurat's work. In 1887 Seurat exhibited the painting again in Brussels with "Les Vingts" ("The XX"), a small group of independent Belgian painters; here it received a more favourable reception.

After finishing "La Grande Jatte," Seurat was so completely in command of his new method that the works that followed required fewer and fewer preparatory sketches. He painted only five more major compositions: "Les Poseuses," 1887 (Barnes foundation, Merion, Pa.); "La Parade," 1887 (Stephen C. Clark, New York city); "Le Chahut," 1889–90 (Rijksmuseum Kröller-Müller, Otterlo); "Jeune Femme se poudrant," 1889–90 (Courtauld institute, London); and "Le Cirque," begun in 1890 (Louvre). In each of these Seurat further explored new facets of the pictorial and technical problems which interested him: the study of space and perspective, of artificial light and varying moods, the sensation of air moving around objects. During the summer months from 1885 to 1890 Seurat painted out-of-doors a number of pure landscapes and marines. Though done in the same strictly scientific method, they are intimate and yet lasting records of nature.

When Seurat died in Paris on March 29, 1891, he had produced 7 monumental compositions, 40 smaller paintings and sketches, about 500 drawings and several sketchbooks. These show him as one of the greatest artists of his time, contributing immeasurably to the development of 20th-century art.

SEVAGRAM, a village in Wardha District, Maharashtra, India, lies 6 mi. SE of Wardha town. Originally called Segaon, the village was renamed Sevagram (Hindi "village of service") by Mohandas Karamchand Gandhi (*q.v.*). In 1936 Gandhi left his *ashram* ("hermitage") on the Sabarmati River, near Ahmedabad, with a vow never to return there until the achievement of Indian independence. He settled at Sevagram, where he continued to direct the independence movement, and founded another *ashram*. Within this he created a model community, which still flourishes. The inhabitants of the *ashram* live a simple existence, growing their own food and weaving their own clothes. The hut in which Gandhi lived still stands in the *ashram*. Another important feature at Sevagram is the Nai Talimi Sangh, the educational centre established by Gandhi, and whose purpose is "learning by doing." Gandhi wanted to evolve a system of education which would fully develop the individual in body, mind, and spirit, and through cooperative work to bring about a new social order from which all would benefit, irrespective of caste. The task of the Nai Talimi Sangh was to build a self-sufficient community providing its own necessities in food, clothing, shelter, and tools and to establish a society which would be able to fulfill its aesthetic, spiritual, and intellectual needs, creating its own art, music, literature, and drama. (D. G. Na.)

SEVAN, LAKE (Ozero Sevan, or Gokcha), is the largest lake in the Armenian Soviet Socialist Republic, U.S.S.R., covering an area of 547 sq.mi. (1,417 sq.km.). It lies in the basin of the Aras (Araks) River, into which it discharges by way of the Razdan, or Zanga, River. The lake lies 6,279 ft. (1,914 m.) above sea level in a basin enclosed by mountain ranges, the Pambakskiy and Shakhdagskiy ranges to the north and the Gegamskiy and Vardenisskiy ranges to the south. The lake falls into two connected parts, Little Sevan in the northwest, smaller but deeper (325 ft.; 99 m.), and the larger, shallower (174 ft.; 53 m.) Great Sevan in the southeast. There are 28 permanent streams flowing into Sevan and many seasonal streams in spring. The largest tributaries are the Masrik, Kyavar-Chay, and Gedak-Bulag. Rainfall is about 15 in. (381 mm.) a year, but evaporation from the lake is exceptionally high, about 33 in. (838 mm.) a year. This high evaporation accounts for 92% of the water loss and the outflow for only 8%. Since World War II a cascade of six hydroelectric plants has been built on the Razdan and the outfall has been artificially lowered to increase the outflow. This has resulted in a slight drop of the lake surface. Average surface water temperatures vary from 1.6° C (35° F) in winter to 17.7° (64°) in summer, and between 1834 and 1954 the whole lake froze on only ten occasions, although certain bays tend to freeze every year. The annual temperature range decreases with depth and below 160 ft. (49 m.) is 3.8° C (39° F). The lake is rich in varieties of fish, including the Sevan trout. The fish caught are canned at Martuni on the southern shore. Chromite is mined in small quantities on the northern shore. The chief town is Sevan at the Razdan outfall, near the highest barrage of the cascade. There are other, small hydroelectric stations on the streams flowing into the lake, notably at Martuni. (R. A. F.)

SEVASTOPOL, a town and seaport in the Krymskaya (Crimean) Oblast' of the Ukrainian Soviet Socialist Republic, U.S.S.R., is located in the extreme southwest of the Crimea on the southern shore of a long narrow inlet, which forms a splendid natural harbour, the best on the Black Sea. Pop. (1959) 148,033. West of this site stood the ancient Greek colony of Chersonesus, founded at the end of the 6th century B.C. According to the historian Strabo the peninsula on which Chersonesus stood was protected by a wall from the inlet to the south coast of the Crimea at Symbolon (now Balaklava). Originally a republic, Chersonesus, threatened by Scythian attacks, became part of the kingdom of Pontus (*c.* 100 B.C.) and then of the Cimmerian Bosporus. It passed to the Romans, being allowed a large measure of autonomy at times, and eventually to the Byzantine Empire. Tradition has it that the apostle Andrew visited Chersonesus, and that St. Clement was banished there by Trajan to work in the quarries.

In 988 or 989 the town fell to Prince Vladimir of Kiev, who was baptized there and took the Orthodox faith back to Kiev. Vladimir restored the city to the Byzantines, but in the 13th century it passed to the empire of Trebizond (or Trabzon). With the growth of the Genoese factories of Caffa and Surozh (Feodosiya and Sudak), Chersonesus lost all importance. After the 13th-century Mongol invasion, the Crimean Tatars established a small settlement, Akhtyar, on the northern side of the inlet. The remnants of the town were razed by the Lithuanian prince Algirdas (Olgierd) in the 14th century. In the 15th century it came under the Ottoman Empire in the reign of Mohammed II, and in 1783 it was annexed by Russia, under Catherine the Great. In the following year, on the orders of G. A. Potemkin, the site was selected for a naval base to protect Russia's newly acquired gains on the Black Sea coast. The new town was given the name Sevastopol ("the august city"). In 1804 Sevastopol became the main Black Sea base and in 1808 a commercial port was opened. The port was constructed under the direction of Admiral M. P. Lazarev, famed for his Antarctic explorations with F. G. von Bellingshausen. During the Crimean War the Anglo-French armies laid siege to Sevastopol, which had been strongly fortified by the military engineer E. I. Todleben. After an eleven-month campaign, from September 1854 to August 1855, the allies captured the key fortress of the Malakhov and the Russians retreated from Sevastopol to the northern side of the inlet. The town suffered considerable damage, but rebuilding was started and its growth was accelerated by the construction of a railway to the port in 1875. In 1894 the commercial harbour was transferred to Feodosiya, and Sevastopol suffered a considerable economic setback. Its principal function thereafter was that of fortress and naval base.

Sevastopol underwent a second siege in World War II, when the town put up a prolonged and gallant defense against the Germans for 250 days, from October 1941 (when the Perekop Isthmus was forced) until July 3, 1942. When resistance was finally overcome the entire town had been reduced to rubble. Liberated in May 1944, Sevastopol began once more to be rebuilt, on the attractive, planned layout of the 19th century. It once more became a major naval base, with commercial functions considerably less important.

There are shipbuilding and repair yards, and bricks, furniture, and foodstuffs are produced. Passenger services link Sevastopol to Odessa and Sukhumi. The town has a museum (1905) devoted to the defense of Sevastopol, and also a vast panorama of the Crimean War siege, 377 ft. long and painted by F. A. Rubo, which is housed in a special building. *See* also CRIMEA; CRIMEAN WAR; BOSPORUS, KINGDOM OF THE; CHERSONESE, TAURIC. (R. A. F.)

SEVEN AGAINST THEBES, in Greek mythology, the seven champions who were killed fighting against Thebes after the fall of Oedipus (*q.v.*). Oedipus' twin sons, Eteocles and Polyneices, whom he had cursed, failed to agree which of them was to succeed to the Theban throne and decided to rule in alternate years. As Eteocles' turn came first, Polyneices withdrew to Argos, where he married Argeia, daughter of the king Adrastus. Her sister Deipyle married Tydeus, son of King Oeneus of Calydon, who was in exile for homicide. At the end of the year Polyneices claimed to rule Thebes in his turn. When Eteocles refused, Adrastus mobilized an army, whose chieftains in Aeschylus' tragedy about the seven were Tydeus, Capaneus, Eteoclus, Hippomedon, Parthenopaeus, Amphiaraus (*q.v.*), and Polyneices. Other authors count Adrastus as one of the seven and omit Hippomedon. In the fighting Tydeus after killing Melampus gnawed his head, and so forfeited the immortality Athena had intended for him. Polyneices and Eteocles killed each other, fulfilling Oedipus' curse. When the sons of the dead seven, the Epigoni or second generation, had grown to manhood, Adrastus again attacked the city and occupied it after the Thebans had evacuated it by night. He died at Megara on the homeward journey.

The story was a great favourite in antiquity. It is the subject not only of Aeschylus' *Septem contra Thebas* but also of Euripides' *Phoenissae*. (D. E. W. W.)

SEVEN CHAMPIONS OF CHRISTENDOM, the name given in medieval tales to the seven national saints of England, Scotland, Ireland, Wales, France, Spain and Italy—*i.e.*, Saints George, Andrew, Patrick, David, Denis, James and Anthony (*qq.v.*) The classical version of their achievements is that of Richard Johnson, *The Most Famous History of the Seaven Champions of Christendome* (3 parts, 1596, 1608, 1610).

SEVENOAKS, a market town and urban district in the Sevenoaks parliamentary division of Kent, Eng., 24 mi. (39 km.) SE of London by road. Pop. (1961) 17,645. Area 5.8 sq.mi. (15 sq.km.). Residential in character, it is the shopping centre for the surrounding rural district. Sevenoaks school and almshouses were founded under the will of William Sevenoke (1432), a foundling who became mayor of London. St. Nicholas Church nearby dates in part from the 13th century. Cricket has been played on the famous Vine ground for over 200 years.

Knole House, since 1456 owned by monarchs, archbishops, and, from *c.* 1603, by the Sackville family, is one of the finest houses in England. Given to the National Trust in 1946 by the 4th Lord Sackville, who lives in a part of it, it contains rare furniture, tapestries, and historic paintings.

See V. M. Sackville-West, *Knole and the Sackvilles*, new ed. (1947).

SEVEN SLEEPERS OF EPHESUS, the heroes of a famous legend which, because it affirmed the resurrection of the dead, had an enormous and lasting success in both Eastern and Western Christendom and even in Islam during the Middle Ages. According to the story, during the persecution of Decius (A.D. 250) seven (in some versions eight) Christian soldiers were concealed near Ephesus (in western Asia Minor) in a cave of which the entry was later blocked up. They fell into a miraculous sleep, from which they awoke in the reign of the emperor Theodosius II (408–450), and after bearing witness to the doctrine of the resurrection of the body they died like saints. The origin of the legend in the 5th century remained unknown until the publication of E. Honigmann's *Patristic Studies* in 1953. This story of Christian apologetics, with its reminiscences of classical mythology, is extant in a number of versions: Greek, Syriac, Latin, Coptic, Armenian, Ethiopic, and Georgian. The sanctuary of the Seven Sleepers near Ephesus long attracted crowds of pilgrims, both Christian and Muslim, many of whom hoped to sleep their last sleep beside these guarantors of survival and resurrection. Austrian excavations have revealed all that remains of the sanctuary and the cemetery. The feast day of the Seven Sleepers is July 27 among Latins, Aug. 2 or 4 and Oct. 22 or 23 in the Greek Church.

SEVENTH-DAY ADVENTISTS: *see* ADVENTISM.

SEVEN WEEKS' WAR, the war fought in the summer of 1866 between Austria, Saxony, Hanover, Bavaria, Württemberg, Baden, Hesse-Kassel, Hesse-Darmstadt, and Nassau on the one side, and Prussia (supported by some minor German states) and Italy on the other. Won by Prussia, it settled the long-standing Austro-Prussian conflict over Germany; and it enabled Italy to annex Venetia.

Causes and Outbreak.—The Empire of Austria (*q.v.*), a conservative form of state, comprising several nationalities loosely articulated, survived in fundamental opposition to the forces of nationalism. These forces were represented in Germany by the ambitious Prussia (*q.v.*) and in Italy by the national monarchy which came into being in 1861 (*see* GERMANY: *History;* ITALY: *History;* also ITALIAN INDEPENDENCE, WARS OF). Within the German Confederation, as it had been established in 1815, Austria and Prussia were rivals for hegemony; and, since only part of the Austrian Empire was included in the Confederation, the rivals were more or less equally balanced. Prussia's scheme for a union of German states without Austria had been quashed by Austria in 1850; but the Austrian plan for uniting the whole Empire with the Confederation had been rejected at the Dresden Conference in 1851. In the Italian war of 1859 Austria had lost Lombardy to Sardinia-Piedmont (nucleus of the Kingdom of Italy formed in 1861), but still retained Venetia.

The emperor Francis Joseph (*q.v.*) on the whole was working toward a lax internal policy and an assertion, against Prussia, of Austria's headship of the German Confederation; from 1865 his chief minister was Richard, Graf Belcredi (*q.v.*), with Alexander, Graf Mensdorff-Pouilly, as foreign minister. In Prussia policy grew in unity and clarity after King William I took Otto von Bismarck (*q.v.*) as his prime minister in 1862. Bismarck set out to create a new Germany and was prepared to destroy the old Confederation. Despite differences about military policy, he found able collaborators in H. K. B. von Moltke (*q.v.*), chief of the general staff, in Albrecht von Roon (*q.v.*), minister of war, and in Edwin von Manteuffel (*q.v.*), chief of the Military Cabinet.

The ostensible cause of the Seven Weeks' War was disagreement over Schleswig and Holstein (*see* SCHLESWIG-HOLSTEIN QUESTION); and the chain of events leading to war began when the Italian, the Schleswig-Holstein, and the German questions were associated in autumn 1864. In September, Napoleon III (*q.v.*) undertook to withdraw the French garrison from Rome within two years, thus giving Italy a free hand to plan the "redemption" of Venetia from Austria. In October, Denmark ceded Schleswig-Holstein jointly to Austria and Prussia. Differences between the two occupying powers raised the German question. Austria aimed at a final settlement in consultation with the German Confederation and was willing that Frederick, duke of Augustenburg, should rule the duchies. Prussia denied the right of the Confederation to consultation and countered the Augustenburg claim with an alternative Oldenburg one. Prussia's next proposal —annexation of the duchies to Prussia—failed when Austria required territorial compensation. In February 1865, also unavailingly, Prussia proposed independence for the duchies, provided that their armed forces were incorporated in Prussia's and that Kiel was ceded to Prussia as a naval base. In March war seemed possible, but tension was relaxed by negotiations.

The Convention of Gastein, on Aug. 14, 1865, divided the duchies. Thenceforward Prussia in Schleswig firmly checked agitation on Augustenburg's behalf, whereas Austria treated Holstein as a temporary trust and respected local feeling. Meanwhile

Napoleon III discussed Germany with Bismarck at Biarritz and St. Cloud, though he supported Austria with a loan publicly subscribed on the Paris *Bourse*. Italy, failing to buy Venice from Austria (Alessandro Malaguzzi's mission to Vienna), signed a trade treaty with the Prussian *Zollverein* (Customs Union) on Dec. 31.

Prussia protested in Vienna against Austria's policy in Holstein (Jan. 26, 1866). Austria next tried to save peace by diplomatic pressure from Saxe-Coburg-Gotha and from Great Britain on Berlin and by a slow *rapprochement* with France; but Prussia took more warlike measures, including negotiations with Italy, which led on April 8 to a treaty binding Italy to join Prussia if German considerations necessitated a Prussian attack on Austria within three months. But the Austrians also put themselves in the wrong: by asking Bismarck (March 16) whether he intended war; by making precautionary troop movements (Austria needed seven or eight weeks to mobilize, Prussia only four); by insisting on territorial compensation if Prussia took the duchies; and by requiring guarantees for the pope if Italy took Venice (which Mensdorff on April 30 privately offered, through Paris, for after the war). The Prussian government improved its standing by proposing on April 9 a German parliament elected by universal suffrage. Francis Joseph put himself further in the wrong when, alarmed by Italian preparations, he decided to mobilize the southern army. This was ordered on April 21, and mobilization for Bohemia on April 27. The archduke Albert (*q.v.*) was appointed to command in the south, and Gen. L. A. von Benedek (*q.v.*) in the north. Prussian mobilization was ordered between May 3 and May 8. Meanwhile Saxony had started arming (April 14); and when the Prussians failed to satisfy the Diet of the Confederation that they had good cause to arm, other pro-Austrian states, namely Bavaria, Württemberg, Baden, and Hesse-Darmstadt, also mobilized.

Napoleon III, with British and Russian support, tried to organize a European congress to settle the three questions, but this plan collapsed on June 3. He subsequently announced a convention with Austria binding himself to neutrality (June 12).

Austria, offering to disarm if legality were restored in the duchies, remitted the question to the Diet (June 1). This was a technical infraction of an Austro-Prussian agreement of Jan. 16, 1864, to keep the settlement to themselves. Prussian troops from Schleswig entered Holstein on June 7. Austria proposed "federal execution" against Prussia; *i.e.* action by the Confederation as a whole. Then Prussia, faced by an adverse vote on a subsidiary motion in the Diet, declared the Confederation abolished (June 14).

On June 15, when Prussian ultimatums to Saxony, Hanover, and Hesse-Kassel, demanding benevolent neutrality, were rejected, Prussian troops invaded the three states; and on June 21, there being no formal declaration of war, the Prussian crown prince Frederick William (the future German emperor Frederick III) informed the nearest Austrian commander that a state of war existed.

The Campaigns.—Making full use of railways for military purposes for the first time, the Prussians had concentrated their troops in the south in an arc 270 mi. long, stretching from the Saxon frontier eastward into Silesia, where there was a common frontier between Prussian territory and Austrian Bohemia. The Elbe Army on the Prussian right drove the Saxons before them into Bohemia, and then joined the 1st Army under Prince Frederick Charles, advancing into Bohemia from positions farther along the arc. On the far left was the 2nd Army, under the crown prince. The Prussians numbered some 285,000 men, of whom about 50,000 were detached for work from Hanover to the Rhineland, and 9,000 for the protection of Upper Silesia. They were armed with the breach-loading needle gun. The Austrians, with some 74,000 men in Italy and some 241,000 in Germany, used a muzzle-loading rifle, and depended much on the bayonet charge.

The Austrians retained their supremacy against the Italians: the archduke Albert defeated Gen. A. F. la Marmora at Custoza (June 24); and Adm. Wilhelm von Tegetthoff destroyed the Italian Navy under Adm. Carlo Persano off the island of Lissa (July 20). In Bohemia, Benedek had the strategical advantage, since he might have concentrated his massed forces against one fraction of the Prussian troops before they united. But the Prussians won early engagements on the Iser and at Gitschin (Jičín) and, in the east, at Náchod and at Trautenau (Trutnov); and by July 1, Moltke had realized his plan to unite the three Prussian armies.

The Battle of Königgrätz (Hradec Kralove), or Sadowa (Sadova), on July 3, 1866, engaged the whole forces of both sides on the Bohemian front. But, since Prussian reconnaissance had been faulty and since Benedek had accepted battle against his better judgment, both sides fought from positions which they had not chosen. Austrian losses were heavy: 20,000 killed and wounded and nearly as many prisoners. The Prussian losses were less than 15,000. The Austrian retreat to Olmütz (Olomouc) was confused, but the Prussians, in almost equal confusion, did not follow up. Both armies had assembled outside Vienna by July 22, when an armistice was signed at Nikolsburg (Mikulov), to be followed on July 26 by preliminaries of peace.

Meanwhile Prussian forces had also been launched against the pro-Austrian states in western Germany. One from Lauenburg on the lower Elbe and one from Westphalia converged on Hanover, while more Prussians, from Wetzlar, struck northeastward at Kassel. The Hanoverian Army (19,000 men) retreated southward into Thuringia, but was prevented from effecting a junction with the Bavarians and so took up a defensive position at Langensalza. There, on June 27, it repelled an attack by a Prussian force of 8,200 from Gotha; but on June 29, it was obliged to capitulate.

Farther to the south, on the Main River, the states loyal to the old Confederation had still two separate army corps, together about 96,000 men, representing Bavaria, Württemberg, Baden, Hesse-Darmstadt, and Nassau. A Bavarian advance toward Thuringia was defeated at Dermbach on July 4 by the victorious Prussians from Langensalza, who then went on to defeat the Bavarians again at Kissingen (July 10) before turning westward to capture Frankfurt am Main. Turning next southward and eastward, the Prussians overcame the Federal army's resistance near Würzburg, which fell on July 27. A few days later an armistice was concluded.

The Results of the War.—The Austro-Prussian Peace of Prague (Aug. 23, 1866) assigned Schleswig-Holstein to Prussia. But Bismarck left Austria itself territorially intact: reconciliation and then alliance with Austria were to become the basis of Germany's later European hegemony. Art. IV of the Peace of Prague, however, recorded Austria's consent to "a new organization of Germany" without Austrian participation.

Prussia annexed Hanover, Hesse-Kassel, Nassau, and Frankfurt outright, thus acquiring the territory which had separated the eastern and the western parts of the Prussian state. Peace treaties, including war indemnities to be paid to Prussia, were concluded with Bavaria, which ceded the small districts of Gersfeld and Orb; with Hesse-Darmstadt, which ceded Hesse-Homburg; with Württemberg; with Baden; and with Saxony.

By the Peace of Vienna (Oct. 3, 1866) Austria ceded Venetia to the French emperor, for transfer to Italy, but retained the southern Tirol and Trieste.

The main issue of the war had been German, and in Germany its most significant results appeared. Prussia could organize the North German Federation (*see* GERMANY: *History*). At the same time the liberal majority in the Prussian lower chamber, which had been defying the government since 1862 (*see* PRUSSIA), capitulated to Bismarck and passed an Act of Indemnity, thus weakening liberalism throughout Germany.

The Austrian Empire, withdrawing from Germany and Italy, was enabled to rearticulate itself. The result was the Austro-Hungarian *Ausgleich* or Compromise of 1867 (*see* HUNGARY: *History*). Austrian stability rested thenceforward on the balance between two partners in the dual monarchy.

Napoleon III suffered a worse defeat than Austria. While the issue of the war was undecided he had been imprecise in demands for territorial compensation. His first impulse after Königgrätz was intervention to curb Prussia, but he stopped short of military pressure. He then formulated demands (July 23) too late. France, in the face of Prussia's new Germany, lost the continental security enjoyed since 1815.

SEVEN WISE MASTERS, THE, a widely spread cycle of stories of oriental origin. Other names sometimes used are *The Seven Viziers* and *The Story of the Seven Sages*. The framework of the stories is that an oriental king entrusted the education of his son to a wise tutor named Sindbad (hence the further alternative titles for the cycle, *Sindbad-name, The Book of Sindbad*, etc.). An occasion arose when the prince was ordered to keep silence for a week. During this time his stepmother, who had tried to seduce him, accused him before the king and sought to bring about his death by seven stories which she related to the king; but her narrative was each time confuted by the tales of the craft of women related by seven sages. Finally the prince's lips were unsealed and the truth was exposed.

It is disputable how far the Middle Persian text (no longer extant) went back to Indian originals. No old Arabic text has survived, but there are modern versions (one included in the *Arabian Nights: see* Nights 578–606 in Sir R. Burton's translation, vol. vi, 1886). The Arabic text gave rise to the Hebrew translation (*Mishle Sindbar*), a Spanish translation (13th century), and the Syrian translation from which derives the Greek version called *Syntipas* (11th century). Of the Persian versions the most important is that of al-Samarqandi (12th century). The Greek version was translated into Latin in the 12th century by Jean de Hauteseille under the title of *Dolopathos* (ed. by H. Oesterley, 1873); this was translated into French by a *trouvère* named Herbers. The German, English, French, and Spanish chapbooks of the cycle are generally based on a Latin original. The Middle English metrical romances are based on the French; the most important of these is *The sevin Seages Translatit . . . in Scottis meter* . . . (1578; ed. by G. F. Black, 1932, Scottish Text Society), by John Rolland of Dalkeith (fl. 1555–60).

Brunner (1933); B. E. Perry, *The Origin of the Book of Sindbad*, offprint from *Fabula*, vol. iii (1960). (S. M. SN.)

SEVEN WISE MEN OF GREECE (SEVEN SAGES), certain historical (late 7th–early 6th century B.C.) Greek figures subsequently grouped together for their practical wisdom. They first appear in Plato (*Protagoras*, 343 a) as Thales, Pittacus, Bias, Solon, Cleobulus, Chilon (*qq.v.*), and Myson of Chen. Elsewhere Periander (*q.v.*) often replaces the obscure Myson, but there are many other variations of the list. The numerous references to them in ancient writers are mostly on three main topics: a contest for a tripod to be given to the wisest, finally dedicated by the winner to Apollo; a banquet held by Croesus or Periander (as in Plutarch's *Symposium of the Seven Sages*, where his place as sage is taken by Anacharsis [*q.v.*]); and their proverbial sayings, including the famous "Know thyself" and "Nothing in excess."

BIBLIOGRAPHY.—*Fragments:* F. W. A. Mullach, *Fragmenta Philosophorum Graecorum*, vol. i, pp. 203 ff. (1860). *See* also Diogenes Laertius, book i; K. Freeman, *The Pre-Socratic Philosophers*, pp. 44–45 (1946).

SEVEN WONDERS OF THE WORLD, the seven preeminent sights of the ancient world. The seven wonders usually so called (except for the Pharos of Alexandria) are those listed in an epigram of Antipater of Sidon (mid-2nd century B.C.) and in an incomplete prose list that goes under the name of his older contemporary, the engineer Philo of Byzantium, but that may well be much later. Some later writers give variant lists.

Pyramids of Egypt.—These are the oldest wonder and the only one substantially in existence today. There are pyramids elsewhere in Egypt, but the best-known lie along a 50-mi. stretch of the Nile Valley west of the river near ancient Memphis (*q.v.*) and date from the Old Kingdom (*c.* 2700–2300 B.C.). The three great pyramids of Khufu, Khafre, and Menkaure at Giza are the most famous, but there are many other pyramids in this region, notably at Abu Roash, Abu Sir, Saqqarah, and Dahshur. (*See* PYRAMID.)

Hanging Gardens of Babylon.—These were not literally "hanging" but "up in the air"—that is, they were roof gardens laid out on a series of terraces irrigated by pumps from the Euphrates. Tradition sometimes made them the work of Nebuchadrezzar, built to console his Median wife who missed the mountains of her homeland, or of the semilegendary queen Semiramis. No certain traces survive.

Statue of Zeus at Olympia.—This was one of the two masterpieces of Phidias of Athens (the other being the statue of Athena in the Parthenon). The statue, over 30 ft. (over 9 m.) high and plated with gold and ivory, represented the god sitting on an elaborate throne with a Victory standing on one hand and a sceptre topped by an eagle in the other. It was famous for the divine majesty and goodness it expressed. The discovery in the 1950s of Phidias' workshop (*see* OLYMPIA) confirmed the statue's date as *c.* 430 B.C. The temple was destroyed in A.D. 426; the statue may have perished then or in a fire at Constantinople 50 years later. No copies survive.

Temple of Artemis at Ephesus.—Little remains above ground of this temple, built by Croesus, king of Lydia, *c.* 550 B.C. and rebuilt after being burned down in 356 B.C., but there are fragments in the British Museum, and excavation revealed traces of both Croesus' and the 4th-century temple as well as of three earlier smaller temples. The temple was famous not only for its great size (over 300 by 150 ft. [about 110 by 55 m.]) but also for the works of art that adorned it. It was destroyed by invading Goths in A.D. 262 and was never rebuilt. Copies survive of the statue of Artemis, an un-Greek representation of a mummylike goddess, festooned with breasts or eggs and ornamented with bees and animals, and wearing a high pillared headdress. (*See* EPHESUS.)

Mausoleum of Halicarnassus.—The monumental tomb of the Carian dynast Mausolus was built, beginning in 353 B.C., by his sister and widow, Artemisia. The architect was Pythius or Pytheos, and the sculptures were the work of four leading Greek artists, Scopas, Bryaxis, Leochares, and Timotheus (*see* GREEK ART: *The Classical Period*). Fragments preserved in the British Museum include the frieze of battling Greeks and Amazons and a ten-foot statue, probably of Mausolus. The Mausoleum was probably destroyed by earthquake between the 11th and the 15th century A.D., and the stones reused. (*See* HALICARNASSUS.)

Colossus of Rhodes.—The Rhodians commemorated the raising of Demetrius Poliorcetes' long siege (305–304) of Rhodes by erecting a bronze statue (reinforced with iron) of the sun god, Helios, over 100 ft. (30 m.) high. It was the work of Chares of Lindus and stood by the harbour, perhaps shielding its eyes with one hand, as a relief suggests; the idea that it straddled the harbour entrance is medieval and impossible. It took 12 years to build (*c.* 292–280), but *c.* 225 it broke off at the knees in an earthquake. The fallen Colossus was left in place until A.D. 653 when the Arabs raided Rhodes and had it broken up and the bronze sold for scrap; it was said there were 900 or more camelloads of metal from it. (*See* COLOSSUS.)

Pharos of Alexandria.—Though famous earlier, this does not appear in any list of wonders until the 6th century A.D. (the earliest list gives the walls of Babylon instead). It was the most famous ancient lighthouse, built by Sostratus of Cnidus for Ptolemy II of Egypt *c.* 280 B.C. on the island of Pharos off Alexandria. It was said to be over 440 ft. (135 m.) high and built in three stages, all sloping slightly inward; the lowest was square, the next octagonal, and the top cylindrical. A broad spiral ramp led to the top, where a fire burned at night. In the Middle Ages the Arabs replaced the beacon with a small mosque. The Pharos was still standing in the 12th century, but in 1477 the sultan Qait Bey built a fort from its ruins. *See* also ALEXANDRIA.

SEVEN YEARS' WAR (1756–1763), the name given to the last great conflict involving all the major powers of Europe, except Turkey, before the French Revolutionary Wars. One aspect of the conflict, that is, the specifically Franco-British aspect, can be understood as an extension of the so-called French and Indian War (*q.v.*), a colonial struggle which broke out in North America and in India before 1756 but ended simultaneously with the Seven Years' War. It is possible to regard the French campaigns in western Germany, against electoral Hanover (dynastically united with Great Britain) and its allies, Brunswick and Hesse-Kassel, as well as the Spanish entry and the consequent Portuguese involvement in the last phase of the war, as by-products of the colonial struggle. From such a point of view, the Seven Years' War properly so named is the Austro-Prussian War of 1756–63, in which Russia was also deeply committed against Prussia till the beginning of 1762 and in which Sweden likewise played a part against Prussia. On the other hand a British alliance with Prussia and a French one with Austria, together with the geographical contiguity of Hanover and Prussia, interwove the fortunes and problems of the two sets of belligerents so closely that, for a practical appreciation, the European campaigns at least should be surveyed as factors of a single war, complex although not coherent. British and European historians, in fact, are often inclined, regardless of chronology, to use the expression Seven Years' War to include also the French and Indian War.

THE DIPLOMATIC REVOLUTION

The Peace of Aix-la-Chapelle (1748), at the end of the War of the Austrian Succession (*q.v.*), left wide grounds for discontent among the powers. In the first place, it did nothing to allay the colonial rivalry between Great Britain and France in North America or in India. Secondly, it confirmed the conquest of the rich province of Silesia (*q.v.*) from Austria by Frederick II (*q.v.*) the Great of Prussia, which the Habsburg heiress Maria Theresa (*q.v.*) resented as an iniquitous price to pay for the recognition of her consort, Francis I, as Holy Roman emperor. Thirdly, Russia was irked by the aggrandizement of Prussia, which constituted a challenge to Russian designs on Poland and on Poland's dependencies along the southeastern coast of the Baltic. Russia, however, under the Treaty of St. Petersburg of Dec. 9, 1747, had accepted a British subsidy and had supplied mercenary troops to the British for use against the French in the last stage of the war; and the French, in resentment, had vetoed any representation of Russia at the peace congress.

The War of the Austrian Succession had seen the belligerents aligned on a time-honoured basis. France's traditional enemies, Great Britain and Austria, had coalesced just as they had done against Louis XIV; and Prussia, the leading anti-Austrian state in Germany, had been supported by France. Neither group, however, found much reason to be satisfied with its partnership: British subsidies to Austria had produced nothing of much help to the British, while the British military effort had not saved Silesia for Austria; and Prussia, having secured Silesia, had come to terms with Austria in disregard of French interests. Even so, France had concluded a defensive alliance with Prussia in 1747; and the maintenance of the Anglo-Austrian alignment after 1748 seemed essential to the duke of Newcastle, British secretary of state in the ministry of his brother Henry Pelham. The collapse of this system and the aligning of France with Austria and of Great Britain with Prussia constitute what is known as the "Diplomatic Revolution," or the "Reversal of Alliances."

The Interests of the Powers.—King George II (*q.v.*) of Great Britain was passionately devoted to his electorate of Hanover whose interests to him counterbalanced those of the British colonies overseas: if war against France for colonial expansion was to be resumed, then Hanover had to be secured against Franco-Prussian attack. France was very much interested in colonial expansion and might exploit the vulnerability of Hanover in war against Great Britain, but wanted not to have to divert forces to central Europe for Prussia's sake. French policy was, moreover, complicated by the existence of the *secret du roi*, that is, the private diplomacy conducted by King Louis XV (*q.v.*), unbeknown to his foreign minister, mainly with the purpose of winning the Polish crown for his kinsman, the prince de Conti (Louis François de Bourbon), and of keeping Poland, Sweden, and Turkey as client states of France, in opposition alike to Russian and to Austrian interests.

Austria and Russia had already concluded a defensive alliance (June 2, 1746) covering their own territory and Poland against attack by Prussia or by Turkey, with a secret clause promising the restoration of Silesia and the countship of Glatz (Klodzko) to Austria in the event of hostilities with Prussia; but their real desire was to destroy Frederick's power altogether, reducing him to his electorate of Brandenburg and giving East Prussia to Poland in exchange for the cession to Russia of Polish rights over the Duchy of Courland. A. P. Bestuzhev-Ryumin (*q.v.*), grand chancellor of Russia under the empress Elizabeth, was no less hostile to France than to Prussia, in view of French activity in Poland, Sweden, and Turkey; but the Austrian statesman W. A. von Kaunitz (*q.v.*), though he was firmly determined to recover Silesia, would not commit himself to Bestuzhev's offensive designs against Prussia so long as Prussia could rely on French support.

Frederick the Great saw Saxony and Polish West Prussia as potential fields for expansion, but could not expect French support if he started an aggressive war for them; and if he joined the French against the British in the hope of annexing Hanover he might fall a victim to an Austro-Russian attack. The hereditary elector of Saxony, Frederick Augustus II, was also elective king of Poland as Augustus III; but Saxony and Poland were physically separated by Brandenburg and Silesia, and neither state could pose as a great power, since Saxony was merely a buffer between Prussia and Austrian Bohemia, while Poland, despite its union with the ancient lands of Lithuania, was a prey to pro-French and to pro-Russian factions. The Prussian scheme for compensating Frederick Augustus with Bohemia in exchange for Saxony obviously presupposed further spoliation of Austria.

Preliminary Negotiations and the Outbreak of the Colonial War.—To gratify Austria, the British government proposed Hanoverian support for the election of Maria Theresa's son Joseph as king of the Romans, that is, agreed successor to his father as emperor; but this proposal foundered on the opposition of Frederick the Great (elector of Brandenburg as well as king of Prussia), whom the other German electors did not dare to antagonize. In 1750, Great Britain acceded to the Austro-Russian defensive alliance of 1746, but without subscribing to the secret clause on Silesia and without obtaining a guarantee of Hanover by the two empires.

Kaunitz in 1750 went as Austrian ambassador to France to urge French participation in Austro-Russian plans against Prussia. France, however, was neither ready to resume diplomatic relations with Russia (severed in 1748) nor willing to connive at the destruction of Prussia, which would have restored Austria to incontestable hegemony in Germany. By 1753, when Maria Theresa recalled him to Vienna to be chancellor, Kaunitz had achieved only a vague atmosphere of Franco-Austrian goodwill.

Meanwhile the French and the British East India companies had been engaged in continuing hostilities, despite the peace of 1748 (*see* INDIA-PAKISTAN, SUBCONTINENT OF: *History: European Settlements*); and in North America, likewise, relations between the colonists had deteriorated steadily from 1752. In 1754 French aggression in North America reached a point which the government in London could no longer pretend to ignore (*see* FRENCH AND INDIAN WAR). The British admiral Edward Boscawen attacked French ships in the Strait of Belle-Ile, off the Breton coast, in June 1755; but before declaring open war on France the British government had still to ensure Hanover, so that British naval superiority could be used to advantage in a largely maritime struggle while France's superior land forces in Europe were held in check by some continental ally of the British.

The Defensive Alliances.—Obsessed with Silesia, Austria was most reluctant to become implicated in the Anglo-French quarrel. Kaunitz took the view that Great Britain should hire German and Russian mercenaries to defend not only Hanover but also the southern Netherlands, whence in previous wars Austro-British and

Dutch operations against France had been launched. The decline of the Dutch as a military force in any case compromised the defense of the Austrian Netherlands, whose value to Austria was furthermore greatly reduced by Anglo-Dutch commercial restrictions. France on the other hand always coveted the Netherlands, and Kaunitz was in fact willing to consider ceding them in return for French help over Silesia. The strength of Austrian troops which Kaunitz was prepared to supply for the defense of Hanover or of the Netherlands against France was far less than what the British required from him.

Rebuffed by Austria, the British sought a new treaty with Russia, like that of 1747; and on Sept. 30, 1755, a preliminary agreement was signed in St. Petersburg by Bestuzhev and the British ambassador, Sir Charles Hanbury Williams. This stipulated that Russia should maintain 55,000 men on the Livonian-Lithuanian frontier, so that they could be promptly moved to defend King George's territory or his allies in Europe in the event of an attack; that in such an event Great Britain would grant to Russia a yearly subsidy of £500,000; and, by a secret article, that Russia in the meantime was to receive £100,000 a year. Bestuzhev, interpreting the treaty as aimed at Prussia, was delighted to have British money to spend on his own projects.

At the same time, without Russia's knowledge, the British were making overtures to Frederick the Great. Afraid of Austro-Russian intentions and alarmed at the Anglo-Russian negotiations, Frederick welcomed these overtures, though the result was unlikely to please his French ally. On Jan. 16, 1756, the Convention of Westminster was signed, whereby Great Britain-Hanover and Prussia agreed to respect one another's territory in Europe and undertook to resist jointly any invasion of "Germany" by a foreign power; but the Austrian Netherlands were expressly excluded from this guarantee.

The Convention of Westminster dismayed Bestuzhev and his empress, who had not yet ratified the British treaty. The empress peremptorily informed the British that the common enemy envisaged in the treaty could only be Prussia; and when the British rejected this interpretation the whole Russo-British arrangement came to nothing. The French government was no less angry at the duplicity of its one ally, Prussia.

The French, in order to get more information about the Anglo-Russian talks and to test the ground for reopening official intercourse with Russia, had sent a Scottish Jacobite refugee, Alexander Mackenzie, known as the chevalier Douglas, on a clandestine mission to St. Petersburg in autumn 1755. Douglas had been briefed by the prince de Conti, for the *secret du roi*, as well as by the French foreign ministry; but the chief agents of the *secret* in Poland had been kept unaware of his mission, lest they should regard the approach to Russia as a betrayal of the anti-Russian line to which their activity had been dedicated. Conti, indeed, seems to have been ready to accept the Duchy of Courland, under Russian protection, or perhaps even marriage to the empress Elizabeth, instead of the precarious Polish crown. The Russian vice-chancellor, M. I. Vorontsov, a persistent enemy of Bestuzhev, received Douglas very favourably; and Elizabeth's indignation at the Convention of Westminster served to accelerate a Franco-Russian *rapprochement*. In April 1756 the Russians offered 80,000 men to Austria for an attack on Prussia.

To Kaunitz the Convention of Westminster gave obvious reasons for self-congratulation. It justified his view that the British alliance was no longer worthwhile; and at the same time it obliged France to accept Austria's overtures, for fear of isolation now that Prussia was defecting. Franco-Austrian negotiations, which had been resumed in summer 1755 between Austria's ambassador Georg Adam, Graf von Starhemberg, and the French abbé de Bernis (*q.v.*), a protégé of Louis XV's mistress, Madame de Pompadour, had reached a stalemate in December; but the announcement of the Convention of Westminster gave them new impetus, and on May 1, 1756, the First Treaty of Versailles was signed (not at Versailles but at Jouy) by the French foreign minister A. L. Rouillé, Bernis, and Starhemberg. This was a defensive alliance between France and Austria, either party undertaking to send 24,000 men to support the other in the event of attack; but it exempted Austria from any obligation to join in war against Great Britain.

The Convention of Westminster and the First Treaty of Versailles are generally taken as the constituent factors of the Diplomatic Revolution, but they did not make war in Europe inevitable. Both being expressly defensive, they might well have had the contrary effect, though Kaunitz at least could see the Austro-French agreement as a step toward enticing France into an Austro-Russian offensive alignment against Prussia. The French seizure of Minorca from the British, achieved in the month April 19–May 20, 1756, did not oblige Prussia to war on the British side, and was of course no concern of Austria's.

Frederick the Great had tried, unavailingly, to present the Convention of Westminster as not inconsistent with his French alliance. He had, accordingly, to profess to regard the First Treaty of Versailles as harmless to Prussia. But that treaty was clearly advantageous to Austria, and so, indirectly, to Russia; and both Austria and Russia were now massing troops on their frontiers nearest to Prussia. In July and as late as Aug. 20, 1756, Frederick appealed to Maria Theresa for assurances of her good intent toward him; but he received no satisfactory reply. On Aug. 29, 1756, Frederick led his army into Saxony, on the way to Austria's Bohemian frontier.

The motive of Frederick's decisive action, which started the European war, has been much debated. Was he frightened into a preventive war, intended only to seize what military advantage he could in the face of imminent aggression by Austria and Russia? Or did he think that the moment had come for another war of annexation?

However much the British were annoyed at the prospect of having to support Frederick if his war went ill, the French were aghast at his action. Whereas they had signed their Austrian treaty in the belief that their hands would be free for the vital war against the British and that they could later choose whether or not to abet an Austrian offensive against Prussia, they now found themselves committed to defend Austria against the unforeseen aggression.

THE COURSE OF THE WAR

The Anglo-French campaigns in North America are described in the article FRENCH AND INDIAN WAR. For those in India see INDIA-PAKISTAN, SUBCONTINENT OF: *History;* also CLIVE, ROBERT. The present article is concerned mainly with the campaigns involving Prussia in central and eastern Europe; but the European campaigns of the war between Great Britain-Hanover and France, with the naval war on the French coast, are also noticed here.

1756.—Crossing the Saxon frontier with 70,000 Prussians on Aug. 29, 1756, Frederick entered Dresden, the Saxon capital, on Sept. 10, while the Saxon Army, not more than 20,000, fell back on Pirna to the southeast. The elector and his minister, Heinrich von Brühl, were offered assurances of Prussia's good intentions, which they naturally mistrusted. An Austrian force of 32,000 under M. U. von Browne, was moving from Bohemia to unite with the Saxons. To prevent this junction, Frederick advanced southward into Bohemia; and Browne was heavily defeated at Lobositz (Lovosice, midway between Dresden and Prague) on Oct. 1. Returning to Saxony, Frederick received the capitulation of the Saxons at Pirna (Oct. 16), whereupon he took nearly all of them into his own service. The elector and Brühl retired to the former's kingdom of Poland.

Russia might have sent forces to Austria's help at once but for the problem of the route which they should take—namely the route across Poland. Poland was a sphere of French influence, which had maintained itself by opposition to Russian designs. For the perfect achievement of an anti-Prussian coalition, it was most desirable, as Kaunitz saw, for Russia and France to come to terms. The Russians, however, saw the new contingency as an occasion for extracting concessions from France with regard not only to Poland, but also to Sweden and to Turkey. The views of the French foreign ministry, ready to admit a swift passage of Russian troops across Polish territory in order to smash Prussia and so to relieve France of the obligation to help Austria, came into

conflict with the *secret du roi*, the primary purpose of which had been to exclude the Russians from Poland at any cost.

In Great Britain, the accession of the elder William Pitt (*see* CHATHAM, WILLIAM PITT, 1st Earl of) to office in November 1756 was to have a decisive effect on the development of the war.

1757.—After weeks of negotiation at cross purposes, Douglas, having returned to St. Petersburg as France's official agent, obtained Russia's accession to the First Treaty of Versailles by signing a secret promise of French help to Russia in the event of an attack by Turkey (Jan. 11, 1757, new style; Dec. 31, 1756, old style). This contradiction of the long standing Franco-Turkish entente was immediately disavowed by the French government; and a personal letter from Louis XV to Elizabeth, the first of an important series, finally secured Russia's accession to the treaty without the objectionable appendix (April 19). An Austro-Russian offensive alliance against Prussia was concluded on Feb. 2, 1757, the parties each undertaking to put 80,000 men into the field and forswearing any separate peace, while secret articles provided for a partition of Prussia.

On May 1, 1757, Austria and France signed the Second Treaty of Versailles, an offensive alliance against Prussia, with further provision for territorial adjustments elsewhere. Austria was to recover Silesia, of course, but would cede the Netherlands for partition between Louis XV and his Spanish Bourbon cousin, Philip, duke of Parma, Piacenza, and Guastalla, whose Italian possessions should then revert to Austria. Militarily, France was to maintain 105,000 men in Germany, in addition to the contingent to be supplied to Austria (which was raised from 24,000 to 30,000), and was to grant an annual subsidy of 12,000,000 livres to Austria. Bernis became French foreign minister in succession to Rouillé.

By a large majority of votes in the Council of Princes of the *Reich*, Austria had secured the declaration of a "war of the Empire" against Prussia. Though Hesse-Kassel, Brunswick, and, naturally, Hanover opposed it, some Protestant states supported Austria, despite Frederick's attempt to pose as the champion of Protestantism against an Austro-French Catholic coalition.

In central Europe the Prussians in April 1757 advanced into Bohemia again. In the Battle of Prague, on May 6, the 66,000 Austrians under Browne and Prince Charles of Lorraine were routed by Frederick's force of 64,000 before they could be reinforced by another Austrian force under L. J. von Daun (*q.v.*). The Austrians lost more than 14,000 men; 16,000 escaped to join Daun, the rest took refuge in Prague itself, which the Prussians, whose losses were about the same, proceeded to besiege. A month later Daun, with more than 50,000 men, moved forward to relieve Prague; and Frederick went to meet him with 34,000. The Battle of Kolin, on June 18, was a great victory for Daun (8,000 Austrian losses, 13,000 Prussian). Raising the siege of Prague, the Prussians evacuated Bohemia.

Prussia meanwhile was exposed to attack from several directions. The French had begun their campaign in the spring by sending L. C. d'Estrées with 100,000 men against the Hanoverians and their allies, who formed the so-called Army of Observation under William Augustus, duke of Cumberland, a younger son of George II. Defeated at Hastenbeck, on the Weser southwest of Hanover, on July 26, 1757, Cumberland withdrew to Stade, near the Elbe estuary, abandoning the defense of the electorate and of Brunswick. A few weeks later, on Sept. 8, the duc de Richelieu (L. F. A. du Plessis), to whom the French command had been transferred, forced Cumberland to sign the Capitulation of Klosterzeven, which stipulated the disbanding of the Army of Observation. Richelieu then advanced on Prussia's western frontier; and at the same time another French army of 24,000, under the prince de Soubise (Charles de Rohan) was crossing Franconia, to join the Army of the *Reich*, namely Austria's German allies, under Joseph of Saxe-Hildburghausen. Furthermore, Sweden, having signed an alliance with France and Austria on March 21, invaded Prussian Pomerania in September, with the intention of annexing it, whether Russia approved or not.

A Russian army of 90,000 men, which had begun to cross Polish territory in May, at last entered East Prussia in August 1757; and on Aug. 30 its general, S. F. Apraksin, inflicted a crushing defeat on the Prussians under Hans von Lehwaldt at Gross-Jägerndorf west of Gumbinnen. To the stupefaction of the world, Apraksin then began a retreat, pleading difficulties of supply. It seems that his conduct was caused, partly at least, by a consideration which was long to bedevil Russian affairs—the fact that the health of the empress Elizabeth, who hated Prussia, was notoriously uncertain, while her heir, the future emperor Peter III, was a self-confessed adorer of Frederick and an opponent of the anti-Prussian war. Any general or statesman who did too much harm to Prussia was therefore risking the displeasure of his future master.

Frederick, with Saxony as his main base, decided first to confront the danger from the west, leaving Frederick Francis of Brunswick-Bevern to face the Austrians in Silesia. To prevent Richelieu's joining Soubise and Saxe-Hildburghausen, he marched first toward Halberstadt; but Austrian successes in Silesia, where Brunswick-Bevern was defeated at Moys (Zgorzelec) on Sept. 7, made him turn eastward again, while Ferdinand (*q.v.*) of Brunswick remained to observe Saxe-Hildburghausen. A daring Austrian raid on Berlin caused further diversion of Frederick's forces. Finally, hearing that Soubise and Saxe-Hildburghausen were together on the move in Thuringia, Frederick went to meet them.

The Battle of Rossbach followed on Nov. 5, 1757. The combined strength of the French and the Army of the *Reich* was at least 41,000, against the 21,000 Prussians; but the aggressive Saxe-Hildburghausen and the more cautious Soubise were at variance; and when at last they began the engagement for which Frederick had hoped, the greatly superior mobility of the Prussians, with the brilliant cavalry leadership of F. W. von Seydlitz (*q.v.*), won the day. In less than two hours' fighting, the Allies lost 7,000 men, the Prussians only 550.

Encouraged by the news of Rossbach, the British government repudiated Cumberland's Capitulation of Klosterzeven. It decided to reinforce the Hanoverians and to transfer the command in western Germany to Ferdinand of Brunswick. In September, a British naval expedition against the French base of Rochefort had been a failure.

In Silesia, the Austrians took Schweidnitz (Świdnica) on Nov. 11 and Breslau (Wroclaw) on Nov. 22. Then Frederick arrived by forced marches from Thuringia to support Brunswick-Bevern. In the Battle of Leuthen (Lutynia), on Dec. 5, 1757, he won the greatest of his victories. With 43,000 men, he attacked the 72,000 under Charles of Lorraine and utterly routed them by an unexpected cavalry charge followed by a heavy bombardment from his artillery. As against Frederick's losses of rather more than 6,000, Charles lost 22,000 men, including 12,000 taken prisoner. Breslau fell to the Prussians again.

In the course of the winter, Lehwaldt drove the Swedes back into their own part of Pomerania, where they were able to hold the Prussians outside Stralsund. Frederick's miraculous energy and masterly handling of well-disciplined troops, combined with Apraksin's retreat, saved Prussia from a situation which, after Kolin, had appeared desperate.

1758.—William Fermor, a Scottish *émigré* in the Russian service, had taken Apraksin's place in autumn 1757. On Jan. 22, 1758, the East Prussian capital, Königsberg, surrendered to him. With the onset of spring, however, the thawing of the snows made the northern roads impassable, so that Fermor was temporarily immobilized. In Russia itself, the still anti-French Bestuzhev was arrested, and power came into the hands of his rival Vorontsov.

Ferdinand of Brunswick, with his Anglo-Hanoverians, launched a successful offensive against the French in Westphalia; and on March 27 he crossed the Rhine at Emmerich, near the Dutch frontier. On June 23, with 40,000 men, he defeated the comte de Clermont (Louis de Bourbon-Condé), with 70,000, at Krefeld; and the effect of this victory, which enabled him to hold all northwestern Germany, was scarcely offset by subsequent French successes farther to the south, in Hesse and in Thuringia. Apart from reinforcing Hanover, the British on April 11 signed a new treaty with Prussia, promising an annual subsidy of 4,000,000 talers (£670,000), while both parties undertook not to make a separate peace with any of the belligerents.

Frederick began the year's campaign with an offensive in Silesia,

where Schweidnitz fell on April 16. He then advanced into Moravia, to lay siege to Olmütz (Olomouc). In July, however, by threatening Frederick's communication with his supply bases, the Austrians forced him to abandon the siege. In the north, meanwhile, a new Swedish attack on Prussian Pomerania was being fended off by Lehwaldt; but the Russians were on the march again, going southwestward from East Prussia toward the Oder River and Brandenburg.

To evade interception by the Austrians, Frederick had to march first northwestward into Bohemia, then northward across Silesia. Fermor's 52,000 Russians, having reached the Oder, began a siege of Küstrin (Kostrzyn) on Aug. 15, but Frederick was at Frankfurt an der Oder by Aug. 20. He then moved round Fermor's east flank and, with a total of 36,000 men, attacked the Russians at Zorndorf (Sarbinowo) on Aug. 25. In the bloodiest battle of the war, the Russians lost 42,000 (21,000 killed), the Prussians 13,500.

Leaving Christoph von Dohna to pursue the defeated Russians, Frederick hastened back to Saxony, to save his brother Prince Henry from attack by superior Austrian forces under Daun, outside Dresden. Daun fell back till he found a strong position at Kittlitz, where he decided to stand with his 90,000 men. Frederick, with 37,000 advanced as far as Hochkirch, never thinking that Daun would venture an offensive. Daun's attack, in the early morning of Oct. 14, took the Prussians by surprise; but Hochkirch was an expensive victory for Daun, as he lost 7,500 men (the Prussians 9,500), and he was unable to interfere with Frederick's retreat into Silesia. Daun advanced on Dresden again, but the news of Frederick's approach through Lusatia caused him to withdraw to Pirna in November.

Hochkirch in any case put new spirit into the French, who after Krefeld and Zorndorf had been inclined to despair of their European war. The duc de Choiseul (*q.v.*) became foreign minister in December, in the place of the exhausted Bernis, whose overtures for peace had been scorned by the British government.

1759.—The Third Treaty of Versailles, already drafted by the end of December 1758, was signed in March 1759 and ratified in May. By this, the French obligations of direct help to Austria in men and money were considerably reduced, and the plan of 1757 concerning the Netherlands and Parma was discarded. The French, however, were still to maintain 100,000 men in Germany.

On April 13 Ferdinand of Brunswick, who had advanced against the French in southwestern Germany, was defeated by the duc de Broglie (Victor François) at Bergen, near Frankfurt am Main; and on July 9 Broglie took Minden on the Weser, which opened the way into Hanover again. When Marshal L. G. E. de Contades joined Broglie, the French had 60,000 men against Ferdinand's 43,000 Anglo-Hanoverians; but on Aug. 1, in the Battle of Minden, Ferdinand contrived to lure Contades into an engagement which, thanks partly to accident, partly to extraordinarily stubborn fighting by British regiments, resulted in the complete rout of the French.

Choiseul had relieved France of the heavier commitments toward Austria in order to prosecute the war against Great Britain with greater vigour. He planned an invasion, with landings around London and in Scotland. To transport and escort the expeditions, the Mediterranean fleet from Toulon was summoned to join the Atlantic fleet at Brest; but on its way northward the former fleet was attacked and scattered by Boscawen in the Battle of Lagos (Aug. 19), off the Portuguese coast. Meanwhile, Edward Hawke (*q.v.*) was blockading Brest. Later, when Hawke withdrew to English waters (Nov. 9), the Brest fleet took to sea. Then Hawke reappeared, and in the Battle of Quiberon Bay (Nov. 20–21) the French suffered a decisive defeat, with most damaging losses. Not only had the project of invasion to be dropped, but also British naval superiority was established for the rest of the war.

Minden, Lagos, and Quiberon Bay, together with outstanding successes in North America—the capture of Ft. Niagara on July 24 and, of far more significance, that of Quebec on Sept. 13 (*see* French and Indian War; also Wolfe, James)—made 1759 the *annus mirabilis* or "wonderful year" for the British. From its strong position, the government began negotiations for peace with France. But on the one hand its terms were too stiff, and on the other its proposals were made in association with its Prussian ally, who at the end of the year was in no situation to expect favourable treatment from his enemies. Furthermore, Austria and Russia strongly objected to France's treating separately with the British.

In May 1759 the Russian command had been transferred from Fermor to P. S. Saltykov. Advancing across Poland through Poznan into Brandenburg with 70,000 men, Saltykov defeated 26,000 Prussians, under C. H. von Wedel, at Züllichau (Sulechów) east of Krossen (Krosno), on July 23. He then moved down the Oder toward Frankfurt, while Daun, from Saxony, sent 35,000 Austrians, under E. G. von Laudon (*q.v.*), northward to join forces with him. Frederick, who had been facing Daun, promptly marched northward likewise, hoping to prevent the Austro-Russian junction; but he failed to do so. Having joined forces with Wedel and with another Prussian force under F. A. von Finck, so that he finally disposed of about 50,000 men, Frederick boldly assailed the enemy in their strong position at Kunersdorf (Kunowice), east of Frankfurt, on Aug. 12. The result was an appalling disaster for Frederick, who in six hours lost more than 18,000 men. Saltykov, however, made no immediate use of his victory; but Daun, advancing against the diminished Prussian forces in Saxony, took Dresden on Sept. 14.

Attempts at junction between Daun and Saltykov were frustrated by Frederick's skilful movements after Kunersdorf; and when Saltykov was forced by lack of supplies to retire from the scene, Frederick turned on Daun again. Finck, however, sent with more than 12,000 men to attack Daun's rear, was surprised by 42,000 of Daun's men at Maxen, south of Dresden, and had to surrender (Nov. 21). The year had been a bad one for Frederick, and the necessity of reinforcing him after Kunersdorf had precluded the full exploitation of Ferdinand's victory at Minden.

1760.—For the campaign of 1760, Russia and Austria chose Silesia as the main field of operations: Saltykov, from Poznan, was supposed to march southward (instead of westward into Brandenburg) and to join forces with Laudon. The latter, on June 23, destroyed a Prussian force at Landeshut (Kamienna Góra) and, on July 26, captured the stronghold of Glatz. Frederick meanwhile, having been watching Daun in Saxony, had first moved eastward against Laudon, then had turned back to besiege Dresden (July 12) on hearing that Daun was moving to Laudon's support. When Daun likewise turned back, Frederick raised his siege and marched in haste through Meissen and Lusatia into Silesia. While 20,000 Russians, under Z. G. Chernyshev, occupied Prince Henry of Prussia in the vicinity of Breslau, the Austrians were converging on Frederick; but on Aug. 15, at Pfaffendorf near Liegnitz (Legnica), a sudden attack launched by Laudon on Frederick's columns, in the hope of preventing their escape from encirclement, was beaten off with heavy Austrian losses. A ruse of Frederick's tricked Chernyshev into retreating, and the Austro-Russian plan for a decisive victory in Silesia came to nothing.

Most of Saxony remained defenseless against Daun, and Brandenburg was open to the Russians. A detachment under G. G. Totleben took Berlin in the night of Oct. 8–9 and was able to retire unmolested on Oct. 13, when Frederick was approaching from Silesia. Daun was able to concentrate 64,000 men around Torgau, against whom Frederick marched with about 45,000. The Battle of Torgau, Frederick's last major victory, began on Nov. 3. The Austrian artillery devastated his attacking troops, but he sent wave after wave of them forward till at last the Austrian line was broken; and on the arrival of his general, H. J. von Zieten (who should have appeared earlier), the Austrians gave up the struggle and retreated. Frederick had lost 13,000 men, Daun 11,000 (including 7,000 prisoners).

In western Germany, Broglie won a victory at Korbach on July 10, 1760, but this was offset by Ferdinand's victory at Warburg on July 31. Hanover was again saved from French invasion; but the subsequent advance of Ferdinand's troops across the Rhine was reversed by C. E. G. de Castries at Klosterkamp on Oct. 16.

George II of Great Britain died on Oct. 25. His grandson and successor, George III (*q.v.*) was far more attached than he to British, as distinct from Hanoverian, interests and had a strong

dislike for Pitt, who was the foremost exponent of the Anglo-Prussian alliance. Without the British subsidies, Prussia could not have fought on.

1761.—By March 1761, when George III's favourite, the earl of Bute (*q.v.*), became British secretary of state for the northern department, the members of the anti-Prussian coalition were at variance in their attitudes toward the war: France wanted a negotiated peace with the British; Austria desired a general congress of the powers, at which the retrocession of Silesia might have been obtained from Prussia; and the Russian empress was still bent on war till Prussia could be carved up. Formal discussions between the French and the British broke down in July because Pitt finally insisted that, whereas the British would go on supporting Prussia, the French should reduce their support of Austria to a minimum and virtually abandon Germany; and that the British should keep all their colonial conquests. Choiseul would not submit to this dictation. To counter it, he fell back on a plan which he had long had in mind—the introduction of Spain into France's war against Great Britain. In August a "Family Compact" between the two Bourbon kings, Louis XV of France and Charles III of Spain, was concluded: Spain would declare war on Great Britain if France had not obtained peace by May 1, 1762; and France would see that Spanish claims against Great Britain were met at the final peace-making. When the British government refused to declare immediate war on Spain, Pitt resigned office (Oct. 5, 1761).

Meanwhile the fighting in western Germany went on as usual. Ferdinand advanced southward from Westphalia but was repulsed by Broglie at Grünberg, between Fulda and Marburg, on March 21, 1761; and a French counterthrust into Westphalia was checked by Ferdinand at Vellinghausen, in the middle valley of the Lippe River, on July 15. By October, however, the French had made very considerable progress eastward. The capture of Belle-Île-en-Mer, off the Breton coast of France, was achieved by a British expedition in April–June.

For Prussia, Frederick's first concern was to prevent the junction, in Silesia, of Laudon's 72,000 Austrians, based on Glatz, with a Russian army of 50,000 under A. B. Buturlin. He concentrated his available forces around Schweidnitz, but after two months of skirmishing and marching the Allies effected their junction between Liegnitz and Jauer (Jawor) on Aug. 23. Cut off from the north and outnumbered by three to one, Frederick entrenched himself at Bunzelwitz, where his enemy did not dare to attack him. When Buturlin withdrew to the north in September, leaving only 20,000 Russians under Chernyshev in Silesia, Frederick could move toward Brandenburg; but Laudon took Schweidnitz on Oct. 1, so that the Austrians could count on wintering in Silesia. In Saxony, meanwhile Daun made gradual progress against Prince Henry; and on the Pomeranian coast the fortress and harbour of Kolberg (Kolobrzeg) fell to the Russians under P. A. Rumyantsev on Dec. 16. No longer sure that he could rely on a British subsidy (since Pitt had gone) Frederick saw that only luck could save him from destruction next year.

1762.—Frederick's salvation came from an event which had so often been expected in error that it could scarcely have been predicted with confidence any more—the death of the empress Elizabeth, which took place on Jan. 5, 1762. This brought the Prussophile Peter III to the Russian throne. On May 5 Peter made peace with Frederick; and on May 22 the Treaty of Hamburg was concluded between Prussia and Sweden, through Peter's mediation. Next, in June, Peter not only allied himself with Frederick for action against Denmark over his ancestral Holstein, but even instructed Chernyshev to help Frederick to expel the Austrians from Silesia. In July, when Peter was deposed and murdered, his widow and successor Catherine II countermanded his positive measures against Denmark and Austria; but she did not renew the war against Frederick.

Daun had been given the Austrian command in Silesia in Laudon's place. Before Catherine's recall of Chernyshev had become effective, when Frederick was trying to recapture Schweidnitz, Daun marched to relieve it, but was defeated at Burkersdorf (Burkatów) on July 21. His second attempt at relief was likewise defeated, at Reichenbach (Dzierżoniów) on Aug. 16; and on Oct. 9 Schweidnitz fell again to the Prussians.

In Saxony, Prince Henry and Seydlitz together won a considerable victory at Freiberg, on Oct. 29, over the Austrians and their German allies. Austria and Prussia signed an armistice on Nov. 24.

In the west, the British government declared war on Spain on Jan. 2, 1762, three months after its rejection of Pitt's advocacy of the same measure and four months ahead of the Family Compact's deadline for Spain's intervention. The Spaniards then attacked Portugal, which the British promptly reinforced. The Portuguese fortress of Almeida fell to the Spaniards on Aug. 25; and overseas they took Colonia do Sacramento, on the estuary of the Río de la Plata, opposite Buenos Aires. These Spanish successes were very heavily counterbalanced by the British capture of Havana, in Cuba, which capitulated on Aug. 13, and of Manila, in the Philippines (Oct. 5). In the same year three important West Indian islands had fallen to the British: Martinique and St. Lucia in February, Grenada in March.

In western Germany, Ferdinand of Brunswick won victories over Soubise at Wilhelmsthal (June 24) and over Prince Xavier of Saxony at Lutternberg (July 23) and took Göttingen (Aug. 16). The French had a success at Johannisberg, near Nauheim, Aug. 30, but lost Kassel on Nov. 1.

Russia's defection from the anti-Prussian alliance convinced Austria that nothing was to be gained from prolonging the war. After the removal of Austria's objections, France could soon come to terms with Great Britain, which in turn had no interest in continuing to back Prussia in a quarrel about Silesia with Austria alone. France in October induced the disappointed Spaniards to join in the negotiations with the British; and on Nov. 3, 1762, anticipating the Austro-Prussian armistice by three weeks, Great Britain and France signed preliminaries of peace, at Fontainebleau.

THE TREATIES OF PEACE

Just as there had, in theory, been two wars, the Franco-British and the Austro-Prussian, so there were two final treaties of peace.

The definitive Treaty of Paris, of Feb. 10, 1763, was concluded between Great Britain-Hanover, France, and Spain, with Portugal expressly understood to be included. By this treaty, France renounced to Great Britain all the mainland of North America east of the Mississippi, excluding New Orleans and environs, the West Indian islands of Grenada, St. Vincent, Dominica, and Tobago, and all French conquests made since 1749 in India or in the East Indies, while Great Britain restored to France the West Indian islands of Guadeloupe, Martinique, Marie-Galante, and Désirade (St. Lucia was also ceded), the Atlantic islands of St. Pierre and Miquelon, the West African colony of Gorée (Senegal), and, of course, Belle-Île-en-Mer. Spain at the same time recovered Havana and Manila, ceded Florida to the British, and received Louisiana, including New Orleans, in compensation from the French. The French moreover evacuated Hanover, Hesse, and Brunswick. The British concessions to France in the West Indies were made, partly, in order to secure the evacuation by the French of Prussian exclaves in western Germany which France claimed to be obliged to occupy pending Austria's settlement with Prussia; but a vociferous section of the British public would have preferred to retain the West Indian islands, or to retrocede Canada instead.

The Treaty of Hubertusburg, between Austria, Prussia, and Saxony, was signed on Feb. 15, 1763, at a hunting lodge between Dresden and Leipzig. Negotiations had started there on Dec. 31, 1762. Frederick, who during his alliance with Peter III had considered ceding East Prussia to Russia if Peter would help him to secure Saxony, finally insisted on excluding Russia (in fact no longer a belligerent) from the negotiations; and at the same time he refused to evacuate Saxony until the elector had renounced any claim to reparation. The Austrians wanted at least to retain Glatz, which they had in fact reconquered; but Frederick would not allow it. The treaty simply restored the *status quo* of 1748, with Silesia and Glatz reverting to Frederick, Saxony to its own elector. The only concession that Prussia made to Austria was to consent to the archduke Joseph's being elected king of the Romans.

Bute's settlement with France was mild by comparison with what Pitt's would have been, both because he hoped for a lasting

peace with France and because he was afraid that, if he took too much, the whole of Europe would unite in envious hostility against Great Britain. But Choiseul had no intention of making a permanent peace; and when France went to war with Great Britain during the American War of Independence (*see* AMERICAN REVOLUTION), the British found no support among the European powers.

Prussia emerged from the war as a great power whose importance could no longer be challenged. Frederick the Great's personal reputation was enormously enhanced, since his debt to fortune (the Russian *volte-face*) and to the British subsidy were soon forgotten, while the memory of his energy and of his military genius was kept strenuously alive.

Austria's prestige was diminished by Prussia's success. Russia, on the other hand, made one great invisible gain from the war—the elimination of French influence in Poland. The First Partition of Poland, in 1772, was a Russo-Prussian transaction, with Austria only reluctantly involved and with France simply ignored.

SEVERINUS, pope from 638 to 640, was elected to succeed Honorius I (d. Oct. 638) but was not consecrated till May 28, 640 (little more than two months before his death, Aug. 2), as the emperor Heraclius hesitated to ratify his election pending his acceptance of the *Ecthesis* (*see* HERACLIUS). Meanwhile the exarch of Ravenna, supported by the Roman soldiery, occupied the Lateran and seized the church's treasure.

SEVERN (Welsh, HAFREN; Roman SABRINA), the longest river in Great Britain (about 180 mi.), rises near the Wye on the northeastern slopes of Plynlimon (Welsh Pumlumon) in Montgomeryshire and follows a semicircular course to the Bristol Channel. It drains an area of 4,350 sq.mi. (11,270 sq.km.) and its average discharge at Bewdley is 2,255 cu.ft. a second. Its course is at first southeasterly, descending in 15 mi. from 2,000 ft. to 500 ft. at Llanidloes.

At this point its tributary, the Tylwch, following the strike of the rocks, is 300 ft. lower than the Wye, less than 2 mi. away. At Llanidloes the river turns sharply to the northeast and follows the glaciated valley of the Vale of Powis (Powys) past Newtown and Welshpool. At Llanymynech it is joined by the Vyrnwy River which has also followed the strike for 12 mi. parallel to the Severn. The headwaters are dammed to form the reservoir of Lake Vyrnwy to supply Liverpool with drinking water.

The united rivers now turn eastward over a plain; the old town of Shrewsbury was here protected from invasion within one of its loops. There is no doubt that the river formerly continued in this direction, joined the Dee and found its way to the Bay of Liverpool, but during the Pleistocene Epoch (Ice Age) a large lobe of ice entered the Cheshire Lowlands from the north, ponding up a lake in the Shropshire Lowlands. The lowest escape for the lake waters might have been by the col at Newport in which case the Upper Severn would have joined the Trent, giving continuous river from Plynlimon to the east coast, but the Newport col was closed by ice and the escape occurred over the high land between Wenlock Edge and the Wrekin at Ironbridge and joined a tributary of the Stour, rapidly deepening the channel and maintaining that course after deglaciation. Through the gorge at Ironbridge the current of the Severn flows swiftly, a matter of some importance in the early iron industry of Coalbrookdale under the Abraham Darbys, the third of whom built the first cast-iron bridge, now disused by traffic (*see* BRIDGES). The Severn continues across the soft red marls of the Triassic, receiving the Stour at Stourport and passing through Worcester, whose cathedral stands on a cliff rising from its steep left bank. The Teme enters from the west just below Worcester, and the Avon from the northeast at Tewkesbury, a yachting and motorboat centre. At Gloucester the river becomes tidal and meanders in increasing amplitude to the sea.

Navigation on this part of the Severn is difficult and is bypassed by a ship canal, more than 10 ft. deep, which leaves the estuary at Sharpness. Opened in 1827, it admits vessels carrying cargo to Gloucester. At Worcester the river is joined by the Worcester and Birmingham Canal and at Stourport by the Staffordshire and Worcestershire Canal connecting with the Midland Canal System, now little used. The connections with the Thames navigation and with the Kennet by the Kennet and Avon Canal are disused. The estuary widens gradually between South Wales and Devon, and the tide, approaching from the west, gradually increases in height and finally the spring tides and the tidal bore (a wave of about 5 ft. in height which reaches up to Newnham) check the outward flow of the river as far as Gloucester. The estuary broadens to more than 2 mi. just above the confluence of the Wye and then narrows to less than 1 mi. where there is a ferry from Aust cliff to Beachley. At spring tides the ferry is suspended for 3 or 4 hr. because of the low water exposing mud. The last railway bridge is the Berkeley viaduct (1,194 yd.) between Sharpness and Lydney, but the Severn Tunnel, 15 mi. further downstream, is 4½ mi. long and carries the railway traffic to South Wales under the English stones which narrow the estuary there. A 3,240-ft.-span suspension bridge over the estuary was constructed in the 1960s, forming part of a road link connecting London with the South Wales industrial area.

The total annual discharge of the Severn is the largest of British rivers and the level of the river rises and falls rapidly in accordance with the variation of rainfall, causing sudden floods, especially in winter. In addition, 78 cu.ft. per sec. are sent to Liverpool from the Vyrnwy. The atomic power station (opened 1962), built on the flats at Berkeley, uses Severn water for cooling purposes. The Severn is a good salmon river and is noted for lampreys. Many of its tributaries, such as the Teme, Vyrnwy, and Avon abound in trout and coarse fish. (AU. M.)

SEVERNAYA ZEMLYA ("Northern Land"), an archipelago belonging to the U.S.S.R., and lying in the Arctic Ocean north of Cape Chelyuskin, the most northerly point of the Eurasian mainland, from which it is separated by Vil'kitskogo Strait. It consists of four large islands—Oktyabr'skoy Revolyutsii, Bol'shevik, Komsomolets, and Pioner—and a number of smaller ones, with a total area of 14,286 sq.mi. (37,000 sq.km.), of which 6,680 sq.mi. (17,300 sq.km.) is ice-covered. The highest elevations, reaching about 3,100 ft. (960 m.), are found at the summits of the ice rises (domes of ice covering land). The ice is mainly in the form of gently sloping ice caps, some of which reach the sea, especially on the east coast, and give birth to icebergs. Komsomolets has an ice cap occupying 65.5% of the surface. The ice cover decreases farther south: on Oktyabr'skoy Revolyutsii it is 55.3% and on Bol'shevik only 29.3%. The islands are chiefly of Paleozoic sedimentary rocks (sandstones, limestones, dolomites), with small intrusions in the south. Vegetation is mainly lichens and mosses, and the fauna includes lemming, arctic fox, polar bear, and wild reindeer. Many sea birds come to nest.

The islands were first reported by the Russian Arctic Ocean Hydrographic Expedition under B. A. Vilkitskiy in 1913, and were explored by a Soviet party under G. A. Ushakov in 1930–32. Soviet weather stations have been permanently manned since the 1930s; there are no other inhabitants.

See G. A. Ushakov, *Po nekhoshdenoy semle* ("In Unexplored Land") (1951). (T. E. A.)

SEVERODVINSK (formerly MOLOTOVSK), a town and seaport of Archangel Oblast' of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the shore of the Dvinskaya Guba (Dvina Gulf) of the White Sea, the so-called Summer Coast, at the western edge of the delta of the Northern (Severnaya) Dvina. Pop. (1959) 78,657. The town was founded after the Revolution as an outport of Archangel, with which it is linked by rail. Timber and timber products from the Northern Dvina basin form a large part of its exports. There are small-scale food processing industries and a fishing fleet is based there. (R. A. F.)

SEVERO-OSSETIAN AUTONOMOUS SOVIET SOCIALIST REPUBLIC: *see* OSSETIA.

SEVERUS, FLAVIUS VALERIUS, Roman emperor 306–307, a Pannonian officer, was appointed *Caesar* to Constantius I on May 1, 305, to rule Pannonia, Italy, and Africa. On Constantius' death on July 25, 306, he was made *Augustus* by Galerius, but he made himself so unpopular in Rome by holding a census of the hitherto tax-free population that on Oct. 28 a revolt broke out headed by Maxentius. Severus invaded Italy next spring but his troops deserted him and he took refuge in Ravenna. He surrendered to Maximian on condition that his life would be spared, but was shortly executed. (A. H. M. J.)

SEVERUS, LUCIUS SEPTIMIUS (146–211), Roman emperor 193–211, was born in Leptis Magna in Tripolitania, North Africa. His grandfather (or perhaps great-grandfather), whose names he bore, is among the earliest fully romanized Africans known to us, described by the poet Statius, in the reign of Domitian (81–96), as an outstanding young man of the equestrian order, nothing foreign in his outlook, through and through an Italian, not African. He owned considerable estates near Rome. When Trajan made Leptis a Roman colony, the elder Severus was chief magistrate in the year of the change, the last *sufes* of the old native town, the first duumvir of the new Roman colony. His two elder sons became senators, one of them receiving a second consulate, an honour reserved to the most distinguished senatorial political leaders. The third son, the future emperor's father or grandfather, remained an equestrian in Leptis.

Young Severus already belonged to the upper ranks of the senatorial aristocracy when he entered the Senate, about 173. He served the normal junior offices of a young senator in Rome, Spain, Africa, and probably Syria. After the early death of his first wife, he married Julia Domna, daughter of a priestly family of Syria. During the political predominance of Commodus' minister Perennis, both Severus and the future emperor Pertinax were out of office, Severus spending his retirement studying the antiquities of Athens. Severus and Pertinax both returned to office on Perennis' fall in 185. Severus governed Gallia Lugdunensis during the critical years of the rising of deserters and poor men, and after a year's quiet proconsulate in Sicily became consul in 190.

In the following year, the irresponsible excesses of the emperor Commodus (*q.v.*) began to verge on madness, to the dismay of the effective heads of the government, the prefect Laetus, the chamberlain Eclectus, and the emperor's mistress Marcia. In 191 Pertinax became prefect of the city; Clodius Albinus and Pescennius Niger were appointed to the most powerful armies of the West and East, Britain and Syria; while Severus took over the largest Danubian army, in Upper Pannonia, with his brother Geta in command of another Danubian army. These appointments were scarcely accidental, since those who made them knew that Albinus was "most loved" of the senatorial Latin aristocracy of the West, that Niger was the "darling of the East," and that the brothers Severus and Geta were politically associated with Pertinax. Commodus' growing insanity made a vacant throne a dangerous probability; West and East both received the senior commander each respected, but between the potential rivals stood Pertinax and the superior forces of Severus and his brother.

The crisis came on the last day of 192, when Commodus' lunacy constrained his advisers to murder him. It passed without disturbance; Pertinax was acclaimed before dawn on Jan. 1, 193, and accepted by the legions and the guards. But when Pertinax was murdered three months later by mutinous guards, who then sold the throne to Didius Julianus, Severus marched swiftly on Rome as the avenger of Pertinax. Niger was proclaimed emperor in the East, but Albinus was bought off with the title of Caesar, heir apparent. Severus disbanded the guards, formerly recruited from the cities of Italy and Noricum, and replaced them with new guard regiments, whose members were promoted from the legions. He marched east to defeat Niger (194), and then fused the victorious and defeated legions in a campaign in northern Mesopotamia. But he could not prevent a significant number of Niger's troops, including numerous technicians, from taking refuge in Parthia, where their knowledge contributed to the increased military efficiency of the enemy in the next generation.

In 197 came the rupture with Albinus, who marched on Rome from Britain. After a rapid march through German territory and the Alps, Severus caught him from the rear and defeated him near Lugdunum (Lyons). Severus now applied the lessons of the civil war: 30 or 40 senatorial and equestrian partisans of the rebels were executed, their confiscated property forming a new treasury department; the three large armies of Britain, Syria, and Upper Pannonia were divided, so that no commander should again control more than two legions; the army's pay was increased, for the second time in 250 years, and its outstanding grievance, that a soldier's marriage was not legally valid, rectified—for a disaffected army was an unreliable defense and a political danger.

The immediate conflicts resolved, Severus heavily emphasized that his rule was to be a return to the golden days of the Antonines. His son Bassianus, better known as Caracalla, had become joint emperor under the name of M. Aurelius Antoninus, and Severus himself took the name of Pertinax, became the putative son of Marcus Aurelius, and asserted a long pedigree back to Nerva on innumerable inscriptions. In practice, the Antonine policies continued. After 197 the Senate and senators were respected, while the work of the great Severan jurists, especially Papinian and Ulpian, continued and consolidated the administrative and legal practice of the Antonines. The lively intellectual activity of the empress Julia Domna strove to reconcile the still discordant concepts of Greek and Latin thought. The political quiet was disturbed only by the dismissal and execution, in 205, of the overweening prefect Plautianus, a near relative of the emperor, and by a war against brigands in Italy. Abroad, a Parthian campaign in 198–202 was conducted as a methodical consolidation and extension of the frontier defenses. After six years in Italy, where the murderous mutual enmity of his two sons, Caracalla and Geta, became openly apparent, Severus took personal command in Britain, reviving Agricola's abandoned dream of subduing the whole island. His armies penetrated at least as far north as Aberdeenshire but were defeated by bog and forest, harassed by guerrilla enemies who would never stand to battle, and killed by disease rather than by weapons, until Severus died at York in February 211.

Severus' reputation suffers because it is depicted by two senatorial contemporaries, Herodian and Dio, who had known the happy times before Commodus and blamed Severus for the disasters of his successors' reigns. To modern writers also his rule appears as the turning point between stability of the 2nd century and the chaos of the 3rd. The essence of that judgment is that he tried without success to put the clock back.

SEVERUS ALEXANDER, MARCUS AURELIUS: *see* ALEXANDER SEVERUS.

SEVIER, JOHN (1745–1815), American frontiersman, Revolutionary War soldier, and first governor of the state of Tennessee, was born in New Market, Va., Sept. 23, 1745. In 1773 he moved westward across the Allegheny Mountains with his wife and children to settle in the region that is now eastern Tennessee. The following year he served as a captain in Lord Dunmore's War against the Indians. During the American Revolution he took part in the Battle of King's Mountain in 1780 and in the next year served under Gen. Francis Marion against the British in the Carolinas and Georgia. In 1784 Sevier took part in the settlers' revolt against North Carolina that led to the formation of the separate state of Franklin and was elected its first governor. Many of the settlers, however, were hostile to Sevier and by 1788 the state of Franklin had collapsed and Sevier had fled into the mountains. The following year, with the help of friends in the East, he regained favour, was elected to the North Carolina senate, and in 1789–91 served in the U.S. House of Representatives.

After North Carolina finally ceded its western territory to the new federal government in 1790, Sevier was a leader among the settlers of the region and when it was admitted to the Union in

1796 as the state of Tennessee he became its first governor. He served for three terms (1796–1801), the maximum allowed by the constitution, and then, after an interval, for three more terms (1803–09). After retiring from the governorship he was elected to the state senate and then to the U.S. House of Representatives, where he served until his death on Sept. 24, 1815. He died near Fort Decatur, Ga., while serving as commissioner to determine the boundary of Creek lands in Georgia.

See C. S. Driver, *John Sevier: Pioneer of the Old Southwest* (1932).

SÉVIGNÉ, MARIE DE RABUTIN-CHANTAL, MARQUISE DE (1626–1696), the writer whose letters not only constitute one of the finest monuments of French literature, but also stand as an epoch-making model for the epistolary genre in any language. She was born on Feb. 5, 1626, in the Place Royale (now Place des Vosges) in Paris. Her father, Celse Bénigne de Rabutin-Chantal, belonged to the old nobility of Burgundy and was a son of the future saint, foundress of the Order of the Visitation (*see* CHANTAL, SAINT JANE FRANCES DE); but his family had been shocked at his marriage, in 1623, to Marie de Coulanges, whose lowborn father, Philippe I de Coulanges (d. 1636), had made a fortune out of tax collecting.

Though her father was killed in battle in 1627 and her mother died in 1633, the future letter-writer's childhood was happy. Brought up by her uncle Philippe II de Coulanges (1595–1659) and his wife Marie Lefèvre d'Ormesson, in the great house in the Place Royale or on the magnificent Coulanges domain at Sucy-en-Brie, she spent her youth surrounded by uncles almost young enough to be her brothers and by cousins (including the songwriter Philippe Emmanuel de Coulanges) only slightly junior to her. She was educated at home and learned Italian perfectly, with some Latin and Spanish. The famous Jean Chapelain and Gilles Ménage (*qq.v.*) were among her teachers; but her uncle Christophe de Coulanges (1607–87), the "most kind abbé" of the letters, had nothing to do with her upbringing, as he already had the abbacy of Livry at the time of her birth.

Marie's background was thus entirely bourgeois. She was introduced into court society and the *précieux* world of the Hôtel de Rambouillet (*see* RAMBOUILLET, CATHÉRINE DE VIVONNE, Marquise de) only after her marriage, in 1644, to Henri de Sévigné, a Breton gentleman of old nobility who bore the courtesy title of marquis and owned the château of Les Rochers, near Vitré. A lamentable creature, he squandered her money before being killed in a duel for a strumpet on Feb. 5, 1651. He left his widow with two children of great beauty: Françoise Marguerite (1646–1705), the future comtesse de Grignan; and Charles (1648–1713), baron de Sévigné.

At this point the abbé Christophe de Coulanges assumed control of his niece's affairs and remained her trusted adviser and friend for the rest of his life. For some years she enjoyed life in the fashionable world, exposed to its dangers but never succumbing to them. Then she devoted herself to bringing her children up. If she was unduly tolerant of their shortcomings, at least she gave them an admirable grounding of culture.

In 1658 Mme de Sévigné broke a promise to lend money, for military equipment, to her cousin Roger de Rabutin, comte de Bussy (*q.v.*). He avenged himself by composing a satire on her, scathing in its cumulative effect though each individual stroke may have been justifiable. Written for his friends' eyes only, this satire was included in the *Histoire amoureuse des Gaules*, published without his consent in 1665, when he and she had made up their quarrel. Their reconciliation had come about after the arrest of the superintendent of the French finances, Nicolas Fouquet (*q.v.*), in 1661. Some quite innocent letters from Mme de Sévigné (on family business) were found among Fouquet's papers, and scandalmongers alleged that they were part of Fouquet's hoard of love letters. Though Chapelain, Ménage, Madeleine de Scudéry, and others rallied to her defense, Bussy alone succeeded in vindicating her reputation, though she had not appealed for his help.

Mme de Sévigné's beloved daughter, whose beauty had caused a sensation at Louis XIV's court, was married in January 1669 to François Adhémar de Monteil, comte de Grignan (d. 1714). Ugly, already twice a widower, and heavily in debt, Grignan was of the most ancient nobility, a former army officer with a splendid bearing and polished manners. Though he owned a palatial château in Provence, he resided in Paris, and Mme de Sévigné hoped that her daughter would remain near her. Soon after marriage, however, Grignan was appointed king's lieutenant general of Provence; and on Feb. 4, 1671, his wife, having stayed behind to bear her first child, left Paris to join him.

Separation from her daughter meant the beginning of acute loneliness for Mme de Sévigné—in the midst, still, of kinsmen and friends. From this loneliness grew the greatest and most important part of her literary achievement, her letters to Mme de Grignan, which, however, she wrote without any literary intention or ambition. Though she and her daughter were parted for an aggregate of less than ten years out of the total from 1671 to 1696, the volume of the letters and the intensity of the writer's grief give the impression of a much longer time. Without her daughter she felt that she had nothing.

Of course there is more than maternal solicitude in the letters, numbers of which, moreover, are addressed to other correspondents than her daughter. They recount current news, events in worldly society, and details of every sort of the writer's life from day to day—her household, her acquaintances, her visits, and her taste in reading (with an inclination to Jansenism paradoxical in one so ready for amusement). For the historian she in fact provides little that he could not discover elsewhere, but her manner of telling her stories makes her version of them unforgettable. Three examples, which she relates not as an eyewitness but from hearsay, may be cited: the suicide of the master cook François Vatel, during a visit of Louis XIV to Chantilly (letter of April 26, 1671); the death of Turenne (letters of July 31 and Aug. 2, 1675); and the great promotion of the Knights of the Holy Spirit at Versailles (letter of Jan. 3, 1689). Once her imagination had been caught by an incident, her sensibility and her powers as an artist were released in narrative.

Mme de Sévigné took no literary model for her artistry. She is known to have been a brilliant talker; and she wrote just as she talked. While she can gallop into a period no less confidently than the duc de Saint-Simon, she can also produce startling effects by suggestive ellipsis. Her style is one of swift movement, even in her descriptions of natural scenery. Before her, critics had held that epistolary literature should conform to certain rules of composition and should observe a unity of tone ("serious" or "playful," "eloquent" or "didactic"). Her letters demonstrate that the only rule is that of spontaneity, a completely natural disorder, the loose manner of conversation, the mixture of the tones; and occasional lapses from linguistic or syntactical correctness can be passed without comment.

When she was not in Paris, Mme de Sévigné spent her last years on visits to Les Rochers, to Livry, to watering places (Vichy and Bourbon), or to Provence. At Grignan from the summer of 1694, she died there of a "continuous fever" (influenza, not smallpox) on April 17, 1696.

BIBLIOGRAPHY.—*Editions:* Six letters from Mme de Sévigné were printed in her cousin Bussy's *Mémoires* (1696), and more than 100 in his *Lettres* (1697). Meagre selections of her letters to Mme de Grignan appeared in two separate editions in 1726, one by Thiériot, the other by Bussy's son, Celse Roger de Bussy-Rabutin. Denis Perrin produced a more ample edition in 1734–37 (614 letters, in 6 volumes) and another, still more ample, in 1754 (772 letters, in 8 volumes). Perrin however "improved" the text according to his own notions, dressing it up to conform to the later standards of Louis XIV's reign, whereas the author's style was really that of an earlier generation. Apart from the publication of three previously unknown groups of letters to particular correspondents in 1756, 1773, and 1814, the next important edition was that by L. J. N. Monmerqué in 1818–19 in 10 volumes (1,40 letters, but not all from Mme de Sévigné); with textual criticisms and annotations which made a great advance on Perrin.

The so-called Grosbois manuscript, an 18th-century transcription came to light in 1820. Full of miscopyings and far from complete, yet contained new letters and new readings of others which seem authentic. Monmerqué went to work again, to produce, for the series Grands Écrivains de France, the monumental edition which Adolphe Regnier completed for him, in 14 volumes (1862–65). In 1872, however, Charles Capmas discovered another manuscript transcription, in six volumes, from which the entire contents of the Grosbois had demonstrably been selected; but extracts from this new material were

published in a strange and misleading presentation (1876), partly out of respect for the "definitive" text of the *Grands Écrivains.* At last, in 1953–57, a three-volume edition by E. Gérard-Gailly appeared in the *Pléiade* series, containing 1,155 letters, with innumerable new passages and thousands of textual restorations.

Biographies and Studies: Of fundamental importance to the study of Mme de Sévigné are C. A. Walckenaër, *Mémoires touchant la vie et les écrits de Marie de Rabutin-Chantal* . . . , 5 vol. (1842–45), with a 6th vol. by A. Aubenas (1865); P. Mesnard, "Notice" prefixed to the *Grands Écrivains* edition (1862); and J. Lemoine, *Madame de Sévigné, sa famille et ses amis* (1926–). There are general appreciations by C. A. Sainte-Beuve (in his *Portraits de femmes,* in his *Causeries du lundi* and in his *Nouveaux lundis*), by A. de Lamartine (1864), by G. Boissier (Eng. trans. 1887), by R. Vallery-Radot (1888), by E. Faguet (1910), by C. Lecigne (1912), by A. Hallays (1921), by Mme M. Saint-René Taillandier (1938), and by A. Bailly (1955). There are also specialist researches in learned periodicals, one group covering Mme de Sévigné's childhood, the other her connections with Brittany. Useful works in English are E. Fitzgerald, *Dictionary of Madame de Sévigné* (1914); P. A. Grouvelle, biographical sketch in the "Carnavalet" translation of the *Letters,* 7 vol. (1928); R. Aldington, preface to a reprint from the translation of 1811 (1937); and W. S. Maugham, preface to the select translation by V. Hammersley (1955).

(E. G.-GA.)

SEVILLE (SEVILLA), the capital of the Spanish province of that name, is the chief city of Andalusia and of all southern Spain. The town is situated on the left bank of the Guadalquivir River about 54 mi. (87 km.) from the Atlantic, about the same distance north of Jerez de la Frontera, the centre of the sherry trade, and 355 mi. (571 km.) SW of Madrid by rail. Seville is an archiepiscopal see and ranks as the fourth city in Spain. It lies low in the river valley, few parts of the city being more than 30 ft. (9 m.) above sea level, and was long subject to floods; these have been mitigated by modern dikes and embankments and by the diversion of the Tagarete, a tributary of the Guadalquivir. The climate is relaxing and in summer it is apt to be excessively hot. Pop. (1960) 442,300 (mun.).

Seville is famous for the magnificently impressive ceremonies and processions of Holy Week, and for the gaieties of the *feria* ("fair") which immediately follows Easter. During the *feria,* Seville is alive with bright costumes, gypsy music, and the flamenco dancing of Andalusia. Important bullfights are held, and throughout these two contrasting weeks the city is full of visitors and many normal activities come to a standstill. Yet at all times the city has great character and a strong feeling of the south, with its many *bodegas* ("bars") open to the pavements, and restaurant meals served out of doors. Typical of many charming touches are the ceramic plaques bearing street names and other plaques indicating houses and streets which figure in the works of Cervantes. Velázquez and Murillo were both natives of Seville, and a house in the Barrio de Santa Cruz was the birthplace, in 1802, of Nicholas Cardinal Wiseman, the first archbishop of Westminster.

The City.—Old Seville is mostly an irregularly planned city, a maze of narrow, twisting streets and small enclosed squares; its houses, built and adorned in the Moorish manner, offer glimpses through doorways to beautiful little arcaded patios. There is a more spacious layout in the district near the cathedral and the Alcázar and in a few of the streets and squares. The broad Alameda de Hércules, laid out under Philip II, with its two Roman pillars bearing statues of Julius Caesar and Hercules, its gardens and rows of trees, is an exception to the normal Seville pattern. More spacious and regular planning is found outside the limits of the old Moorish and medieval city, and the Maria Luisa Park is a particularly beautiful district; its avenues lead to the elaborate buildings of the Hispanic-American Exhibition of 1929. But east of the Alcázar the Barrio (or quarter) de Santa Cruz, which was once the ghetto, is typically picturesque in the Sevillian manner; it is popular with tourists for its associations with Doña Elvira, Don Juan, and Figaro. Over the river is the centre of Seville's ceramic industry, the Barrio de Triana, with its attractive narrow streets; in the modern suburb of Los Remedios next to it is the tobacco factory built to replace the one associated with the opera *Carmen.*

In the Marcarena quarter there is a much altered section of the Roman walls, and some of the Roman aqueduct is also preserved on the eastern side of the city. The chief Roman remains, however, are those of the large town of Itálica, the birthplace of the

JOSEF MUENCH

THE TORRE DEL ORO (TOWER OF GOLD), PART OF THE ALCÁZAR PALACE FORTIFICATIONS, ON THE GUADALQUIVIR RIVER, SEVILLE. THE GIRALDA, THE BELL TOWER OF THE CATHEDRAL, CAN BE SEEN IN THE BACKGROUND AT LEFT

emperors Trajan and Hadrian, at Santiponce 5 mi. NW. The ruins of the amphitheatre are especially imposing, and the outlines of streets and houses are also visible. By mid-20th century much of Itálica had yet to be excavated from beneath fields and olive groves.

From the Arab or Moorish period the most splendid survival is the Alcázar Palace, which was begun in 1181. A decagonal, brick tower, the Torre del Oro (1220), part of the outer fortifications, is a striking feature on the riverbank; it houses a maritime museum. The splendid courts and state apartments in the Alcázar, from the Muslim or the Mudejar period when the Moorish style continued under Christian rule, may be compared in beauty with those at Granada. Other examples of Moorish building are the tower of the Church of San Marcos (once the minaret of a mosque), the Puerta del Perdón, two sides of the cathedral's Patio de Naranjos (court of orange trees), and the lower part of the Giralda, or belfry, of the cathedral. This was the minaret of Muslim Seville's chief mosque. Built about 1180–1200 by Ahmad ibn Baso for Yusuf I, it has surfaces almost entirely covered with beautiful yellow brick and stone paneling of Moorish design; its upper stages were added during the reign of Philip II. Seville also has several fine Mudejar buildings, the Casa de Pilatos and the Casa de las Dueñas being among the best.

The building of Seville's churches started soon after the conquest of 1248. Among them, San Marcos and Santa Ana are good specimens of comparatively early Spanish Gothic. The exquisite chapel of the Old Seminary is of the 15th century. The brickwork of the Convent of Santa Paula is late Gothic and is brightly decorated with Italian majolica.

For a century and a half the principal mosque, with adaptations, served Seville as its cathedral. The new Cathedral of Santa Maria de la Sede, the second largest in area of all Gothic churches, was started in 1402; most of the building was finished by 1506. It has stylistic affinities both with the late Gothic of France and with English Perpendicular. The nave and choir are flanked by vast double aisles, the external breadth being 295 ft. and the nave vault 100 ft. above the pavement. The royal chapel at the east end, with the tombs of Ferdinand III and Alfonso the Wise, was completed by 1575 in the Plateresque style, and at the northwest corner is the Baroque chapel, added in the 17th century, which serves as the parish church. The numerous windows of the cathedral range in date from the 15th to the early 19th century. Pictures include works by Alejo Fernández, Luis de Vargas, and

Murillo. The numerous chapels are enclosed by iron screens (*rejas*) of varying dates, many of them of sumptuous beauty, and many of the altars are backed by fine altarpieces of the Baroque and earlier periods. In the choir the richly carved 15th-century stalls lead on, past two huge iron screens, to the high altar and its great Gothic reredos, a towering masterpiece of carved woodwork started by the Fleming Hyamson Dancart in 1482 and finished half a century later. Before the high altar, at the festivals of Corpus Christi and the Immaculate Conception, the altar boys (*seises*) stage their unique ceremony of a dance with castanets, an old custom the origin of which is obscure.

Renaissance and Baroque churches in Seville have domes or belfries picked out with brightly coloured *azulejos*, or decorative tiles. La Magdalena, San Luis, and San Salvador are among Seville's most imposing Baroque churches. The Palace of San Telmo, once a naval academy and now the diocesan seminary, has a splendid Churrigueresque (*see* CHURRIGUERA, JOSÉ) portal, and Rococo art is brilliantly represented by the ornate work in Santa Maria la Blanca and in the chapel of San José in the very middle of the city. Severer Renaissance architecture is seen in the Casa Lonja, built from designs by Juan de Herrera, the architect of the Escorial, and finished in 1598. First used by the merchant community, the building has housed the Archivo General de Indias since 1785; the impressive staircase of red marble was built for this new purpose by Charles III. The Archivo has a superb collection of books, plans, manuscripts, and several million documents, all bearing on the history and administration of Spain's empire in the Americas.

The university, originally a school but given university status in 1502, now uses the large, imposing fortified buildings of the old tobacco factory, completed in 1757 under Ferdinand VI. It has a charming chapel and a richly sculpted Baroque portal. The museum, formerly the Mercedarian convent, has a fine collection of paintings of the Seville school, which flourished during the 16th and 17th centuries. Among the artists represented are Velázquez, Murillo, Goya, and Martin de Vos.

History.—Seville appears originally to have been an Iberian town. In the Roman period it flourished from the 2nd century B.C. onward, and was captured by Julius Caesar in 45 B.C., after the defeat of the Pompeians at Munda. Under the Empire it became the headquarters of one of the four judicial subdivisions (*conventus juridici*) set up in the province of Hispania Baetica, the capital of which was at Córdoba. Early in the 5th century the Silingian Vandals made it the seat of their empire; later the town passed under Visigothic rule. The Moors besieged and took the city in 712, and under their rule Seville flourished greatly. Idrisi speaks in particular of its great export trade in the olive oil of Aljarafe. About 741 much of this part of Spain was occupied by Syrian Arabs from Emesa, and a member of one of these Emesan families, Abu'l-Qasim Mohammed, cadi of Seville, headed a revolt of the townsmen against the Berbers in 1023 and became the founder of the Abbadid dynasty whose capital was Seville. This regime lasted under his son al-Mu'tadid (1042–69) and his grandson al-Mu'tamid (1069–91), after which the city was taken by the Almoravides. The Muslims of Spain found the later years of Almoravide rule highly oppressive, and were even ready to welcome the victorious arms of Alfonso VII who was crowned emperor in 1135. Eleven years later all Andalusia rebelled, and Almohade troops took Seville in 1147. Under the Almohades, their capital, Seville, was the scene of great prosperity and artistic endeavour, but after the decline of that dynasty Ferdinand III captured it for Christendom in 1248; temporary ruin followed as many thousands of its people are said to have gone into voluntary exile.

Seville's geographic position was too favourable for it to decline altogether as a trading port, however, and by the 15th century it was again able to derive full benefit from Columbus' discoveries and Spanish colonization in the Americas. The Casa de Contratación, or House of Trade, was established there in 1503, and Seville thus became the temporary residence of the casa's *pilotos mayores*, or chief navigational advisers, who included Amerigo Vespucci and Sebastian Cabot. For two centuries Seville held a dominant position in Spain's new world commerce, and many emigrants to the Americas sailed from its quays. Hydrographic conditions in time favoured the Atlantic port of Cádiz, and Seville, despite its great silk factories, shared in Spain's 17th-century economic decline. In 1800 an outbreak of yellow fever killed about 30,000 people, and in 1810 the city was severely plundered by the French under Marshal Soult.

Politically, Seville long had a reputation of peculiar loyalty to the throne and was therefore much favoured by the Spanish monarchs. For its loyalty in the revolt of the Comuneros, Charles V gave it the motto *Ab Hercule et Caesare nobilitas; a se ipsa fidelitas* ("Nobility came from Hercules and Caesar; loyalty from within itself"). The Central Junta against Napoleon (the committee to organize resistance to invasion by the French) was formed in Seville in 1808, and in 1823 the *Cortes* brought the king with them from Madrid to Seville. In the civil war of 1936–39 it was early occupied by the nationalists and remained in their hands; as a result its churches and other fine buildings escaped virtually intact. Since the civil war Seville has retained its position as the leading commercial centre of Andalusia and has fully regained its attraction for tourists and lovers of architecture.

(BN. L.)

Commerce and Industries.—Although an inland port, Seville was always one of the chief outlets for the wealth of Spanish trade. The windings of the Guadalquivir, from its mouth to Seville, where it is still tidal, render it dangerous for shipping. The construction of a 4-mi.-long ship canal from the Punta de los Remedios to the Punta de los Verde—two points between which navigation was especially dangerous—was therefore undertaken in 1907. On its completion, vessels drawing 25 ft. were enabled to reach Seville. Especially after World War II shipbuilding was greatly developed downstream from the town. One of the chief shipyards is owned by the Empresa Nacional Elcano and is supported by the government. The left bank quay, 4,500 ft. long, is equipped with powerful cranes and has large storage sheds.

The principal exports are sherry and other wines; Seville oranges and lemons, olives, oil, and cork; pyrites, mercury, and iron and lead ores. Hemp, jute, and farm implements are also manufactured, and there are iron foundries and a royal artillery works. Seville has a famous tobacco and cigar factory associated with Carmen in Bizet's opera of that name. Pottery has been the characteristic industry of the Triana from time immemorial, and there is a porcelain and earthenware factory in the Carthusian convent. Justa and Rufina, the city's patron saints, are said to have been potters. Nearby butane gas deposits have also increased Seville's commercial potential.

The main-line railway from Seville to Madrid goes via Córdoba and there are branch lines to Badajoz and Lisbon; other lines connect Seville with Huelva and Cádiz. It is linked by road to other main cities. From the airport at San Pablo, 7½ mi. from the city, there are services to Madrid, Valencia, and Morocco.

(SH. H.)

SEVILLA PROVINCE, one of the eight provinces forming Andalusia, centres along the lower Guadalquivir Valley. Area 5,406 sq.mi. (14,002 sq.km.). Pop. (1960) 1,234,435. The province has varied relief, being bordered northwest by the Sierra Morena and south and southeast by the Sub-Baetic ranges of the Sierras de Algodonales (3,704 ft. [1,129 m.]) and de Yeguas. Between these ranges the Guadalquivir trough forms rolling tablelands (*campiñas*) at about 150–600 ft. (50–200 m.). At Palma del Río, at the confluence of the Genil River, the Guadalquivir Valley broadens and the river more than doubles its volume. The Genil, fed by the generous rainfall and snows of the Sierra Nevada, and the Guadaira, fed from the Sub-Baetic ranges, provide a striking contrast to the meagre seasonal flow of the minor tributaries from the Sierra Morena. The rugged relief and thin soils of the Sierra Morena support few people, unlike the richer tablelands of the southern *campiñas* with their olive groves, cereals, and cotton. Cultivation in large estates (*latifundia*) preponderates around the large centres of Écija (49,762 [mun.]), Carmona (28,216 [mun.]), Marchena (20,600 [mun.]), Utrera (41,126 [mun.]), Morón de la Frontera (35,248 [mun.]), and Osuna (20,775 [mun.]). Very different are the numerous small towns along the north bank of the

Guadalquivir, many on Roman sites, practising horticulture in smaller holdings, but isolated from the main lines of communication. Below Seville, capital of the province, the navigable Guadalquivir falls only 30 ft. (9 m.) to the sea 88 mi. (142 km.) downstream. Forming a lake in classical times (Lacus Ligustinus), the marshy plains of Las Marismas are shut off seaward by littoral sand dunes, Arenas Gordas. These plains are the haunt of wild fowl, bulls are pastured there, and land reclamation projects have long been in progress. Apart from its agricultural wealth, the province yields copper, iron ore, and coal. (J. M. Ho.)

SÈVRES, a town of northern France, in the Région Parisienne, lies on the Seine River midway on the main road from Paris to Versailles. Pop. (1962) 20,119. It is famous for the porcelain factory, Manufacture Nationale de Porcelaine, established there in 1756 and moved in 1876 to buildings between Sèvres Bridge and Saint-Cloud Park. The old building contains a mixed *lycée* and also the international centre for pedagogical studies. (*See* also POTTERY AND PORCELAIN.) There is also a ceramics museum and a technical school of ceramics. There are two ammunition (percussion caps) factories. In 1920 the Treaty of Sèvres (later superseded by that of Lausanne) between the Allies and Turkey was signed at Sèvres. (RE. H. B.)

SEWAGE DISPOSAL constitutes one of the main barriers between disease organisms and man. Every city, village, and town is faced with the problem of disposing of water-carried wastes. The degree of purification that must be attained is dictated by the amount of treatment that can be accomplished by unaided natural processes—physical, chemical, and biological. The relative volumes of treated sewage and the quantity of water in a stream, lake, sea, or ocean into which the treated sewage is discharged and the use of the mixture for industrial water, recreation, or as a water supply govern the degree of treatment.

Methods of sewage treatment may be grouped broadly into (1) primary, such as sedimentation or passage through fine screens, to remove the grosser solids, and (2) secondary, such as trickling filters, sand filters, or the activated-sludge method, by which the dissolved and colloidal organic matter in the sewage is collected by microorganisms and oxidized to stable forms that will not cause odour or nuisance.

Sewage is generally divided into two classes: domestic or sanitary sewage and industrial wastes, carried in what are called "separate sewers"; and storm water or storm sewage, carried in "storm-water drains." In some cities both classes are collected in one system, in "combined sewers." In the United States no attempt is made to treat storm sewage unless it is mixed with domestic sewage; in such cases it is feasible to attempt treatment of only a small portion of the combined sewages.

The underground conduits, or sewers, constituting the system through which sewage is conveyed to the point of disposal are usually laid under public streets and form an intricate network of mains and branches. House sewers connect the plumbing systems of buildings to lateral sewers in the streets. The sewage from laterals discharges into submain or main sewers, from which it discharges into trunk and outfall sewers. Interceptors are generally laid transversely to the submain and trunk sewers to intercept the dry-weather flow of sewage and such additional surface and storm water as may be necessary. Relief sewers are provided to carry a portion of the flow from a district already served by sewers of insufficient capacity, and thus preventing overtaxing the latter. Storm-water overflow sewers are provided to carry flows in excess of the capacity of the main or intercepting sewers.

The average volume of domestic sewage is about 100 gal. per person per day. The measure of strength of the sewage is commonly based on the suspended solids and on the biological oxygen demand (BOD), which indicates the amount of oxygen required for biological decomposition of the organic matter. Both strength and volume may be markedly influenced by industrial wastes.

Cities situated on large rivers, which thus have a large quantity of water to dilute their waste waters, do not need to achieve the high degree of sewage treatment that is required, for example, of a city that must discharge treated wastes into a lake from which its drinking water is obtained.

The use of specially constructed sewers dates to the time of Babylon and ancient Greece, but only during the 19th and 20th centuries has the water-carriage system for removal of household and factory wastes been gradually adopted in the Western world. Cities such as Paris, London, Boston, and New York had sewers early in the 19th century. About the earliest application of engineering principles occurred at Hamburg, Ger., in 1842, at London in 1852, and at Brooklyn, N.Y., in 1857.

With the adoption of the water-carriage system, the transfer of wastes from home and factory to the nearest watercourse brought serious nuisance and health problems. Often the stream served the dual purpose of sewage disposal and water supply, and hence there were frequent, disastrous epidemics of cholera, typhoid fever, and other waterborne diseases. Gradually, corrective measures were devised, but at a slower rate than sewers were being built. Effective methods of sewage treatment had their beginnings only in the last quarter of the 19th century, and the greatest development did not occur until the second quarter of the 20th.

SEWAGE TREATMENT

Primary Treatment.—*Screening.*—Pieces of wood, bundles of rags, pieces of wire, and other sizable material are often found in sewage. Such material must be removed because it can damage the pumps. In most cases screens with clear openings of about 1¼ in. are used. The screens are cleaned by a mechanism actuated by an electronic timing device. The screenings are only a small part of the total solids found in sewage, but in a large city they may amount to several truckloads per day. Disposal may be accomplished by burial, incineration, or by grinding and returning the screenings to the sewage.

Grit Removal.—Gritty materials such as sand and ashes must be removed to reduce wear of pump surfaces and accumulation of grit in parts of the treatment plant where it will be a nuisance. Grit is separated from lighter sewage solids by regulating velocities of flow through channels so that the fast-settling grit will be deposited while the lighter solids are carried on. Grit is removed from the channels and buried; if it has been freed of organic material by washing, it can be used as fill dirt. The equipment used in washing grit is the same type as that used in the mining industry to separate ore from debris.

Sedimentation.—Sewage from which screenings and grit have been removed still contains suspended solids, about one ton per 1,000,000 gal. A city of about 500,000 persons has a sewage flow of nearly 100,000,000 gal. per day and consequently has the problem of disposing of approximately 100 tons per day of solids. Some of the solids will settle if the liquid is allowed to remain quiescent for a short period.

The standard method is sedimentation in a tank through which the sewage flows continuously for two to four hours. The tank units are eight to ten feet deep, round or rectangular. Round tanks employ a central feed, and the settled sewage is discharged over a peripheral weir. Rectangular tanks, generally four or five times longer than they are wide, have an inlet at one end and discharge at the other. Various methods are used to minimize currents that may interfere with the sedimentation. The solids (or sludge) that settle are concentrated in a central hopper in circular tanks, or in a hopper at the inlet end of rectangular tanks, by means of scrapers or collectors that may be operated either continuously or several times a day.

Approximately 40 to 55% of suspended solids can be removed by sedimentation, reducing the biological oxygen demand by nearly the same amount. Practically none of the dissolved solids can be removed by the process.

The German engineer Karl Imhoff developed a tank with an upper compartment for settling and a lower compartment where solids are decomposed by bacteria. The Imhoff tank is a simple device containing no moving mechanical parts. It has been used successfully in many parts of the world, but in new plants it has been gradually replaced by settling tanks with mechanisms that permit more rapid handling of sewage. Imhoff tanks are often used for settling prior to filtration through sand beds.

Chemical Precipitation.—Some cities on large rivers have

been able to treat sewage sufficiently by primary sedimentation, disposal of the settled solids, and chlorination of the effluent, the liquid remaining after sedimentation. Other cities have found it necessary to provide for chemical precipitation during periods when the rivers are low. The chemicals coagulate some of the colloidal solids into particles of a size and weight that will settle. The chemicals—commonly aluminum sulfate, ferric chloride, and ferric and ferrous sulfates—are added to the sewage and quickly mixed with it in a small tank. The mixture then passes to a flocculating tank where it is gently agitated with stirring paddles. The floc is formed in 20–40 minutes and the flocculated sewage flows to a settling tank. The amount of chemicals required depends upon the characteristics of the sewage, varying from 400 to 700 lb. per 1,000,000 gal. Addition of chemicals makes it possible to remove 80–90% of the suspended solids and reduce the biological oxygen demand by 65–75%. The amount of dissolved organic solids removed by chemical treatment is very small.

Secondary Treatment.—The effluent from primary sewage settling processes contains some suspended and much dissolved and colloidal matter that will decompose, often creating nuisance and odour. Various methods of secondary treatment are used, among which trickling filters, the activated-sludge process, and sand filters are commonest.

Trickling Filters.—A trickling filter is a six-to-eight foot deep bed of stones two to four inches in diameter. Purification is accomplished by a film of bacterial slime and other organisms on the surfaces of the stones, rather than by mechanical filtering action as is suggested by the name given to the equipment. The sewage is applied to the stones in a thin sheet or spray, with short intervals between applications, and allowed to trickle down through the bed. Application is principally by means of rotating arms onto a circular bed, although some plants used fixed-spray nozzles and square or rectangular beds. The standard rate of application is 300,000 gal. per acre per day per foot of depth, though some installations operate at rates twice as great. Trickling filters are usually enclosed in concrete walls. Openings in the walls or vents to the underdrains assure an adequate supply of oxygen for the microorganisms. After passing through the trickling filter the sewage usually goes to a secondary settling tank for removal of organic matter that has sloughed off from the stones of the filter. Trickling filters, together with primary treatment and final sedimentation, will remove 85–95% of suspended solids and reduce biological oxygen demand by the same amount.

High-rate trickling filters are so named because 10,000,000 to 30,000,000 gal. per acre per day of liquid load may be applied to their surfaces. This rate is attained by recirculating effluent over the filter along with the settled sewage. Application of sewage and effluent to the stones is continuous and the rate is usually high enough to eliminate accumulations of large quantities of slime.

The sludge that accumulates in the settling tanks of both types of trickling filters must be removed and disposed of.

Activated Sludge.—The activated-sludge method utilizes biologically active sludge mixed with treated sewage and agitated in the presence of an ample supply of air in an aeration tank for four to ten hours. Suspended solids and many organic solids are quickly absorbed or adsorbed by the activated sludge, while organic matter is oxidized by the microorganisms in the sludge. The sludge, representing about 25% of the total volume, is separated from the liquid in a secondary settling tank and then is passed through the aeration tanks again.

Aeration may be accomplished by means of compressed air blown through porous plates or tubes or admitted through specially designed jets, by means of mechanical agitators, or by a combination of these methods. Porous plates, tubes, or jets are generally set in rows either across the aeration tank or along one side. In mechanically aerated tanks, the commonest arrangement is a revolving mechanism that agitates the sewage and sludge mixture and aerates it by throwing a portion of the mixed liquor through the air or by drawing air into a downdraft tube and discharging it under the surface in bubbles.

Advantages of the activated-sludge method include flexibility, permitting almost any desired degree of treatment by varying the period of aeration, and efficiency: it removes about 95% of bacteria and more than 90% of suspended solids and of organic matter. Accumulated solids must be removed from the system and disposed of in one of several approved ways.

Sand Filters.—These are beds of sand, about 36 in. deep and underdrained, on which raw or settled sewage or the effluent from trickling filters is applied for final treatment. Sand beds produce a clear, sparkling, and highly stable effluent. The beds are periodically cleaned by backflushing.

Sludge Disposal.—Sewage sludge is the accumulated settled solids deposited in tanks or basins and containing more or less water to form a semiliquid mass. The various sludges are: (1) primary sludge; (2) chemically precipitated sludge; (3) trickling filter secondary sludge; (4) excess activated sludge; and (5) digested sludge.

Sludge may be hauled or pumped to sea, dewatered on vacuum filters, and incinerated or sold for fertilizer immediately after removal from the sewage-treatment process, or it may be digested by microorganisms under controlled conditions to reduce the organic content prior to ultimate disposal. Digestion tanks are usually circular, with diameter as required and 15 to 25 ft. deep. They are usually heated to about 95° F (35° C), optimum temperature for the microorganisms that decompose the organic matter. A standard design provides for two or three cubic feet of heated digestion tank per person contributing to the sewers; twice that volume is required for unheated tanks. About 30 days ordinarily is needed for complete digestion in a heated tank.

In the process of digestion the microorganisms produce carbon dioxide and methane—from 0.5 to 1.3 cu.ft. per day for each person contributing to the sewers—which may be collected and used to heat the digestion tanks and buildings and in gas engines that drive generators, sewage pumps, and air compressors.

At the end of the digestion period the sludge may be used in liquid form as fertilizer, but usually it is dried first, on sludge-drying beds. These consist of about 12 in. of sand supported on 6 to 8 in. of gravel, the whole being underdrained by open-joint tile spaced 8 to 10 ft. apart. The sludge can be removed from the beds after two to three weeks. If properly digested, it is not objectionable and can be used for fertilizer, or dumped. It is excellent fertilizer for grass and shrubs but should not be used to fertilize vegetables that are to be eaten raw.

Before sludge can be dried and sold as fertilizer, or incinerated part of the water must be removed by vacuum filtration. A vacuum filter consists of a drum covered with a filtering medium, a vacuum being maintained inside one quadrant. As the drum is rotated through a tank containing sludge (to which coagulating chemicals have been added), the liquid is drawn into the drum while the solids are collected as a mat on the filtering medium. The process is continuous, the sludge mat being peeled off as the drum revolves. A vacuum filter will dewater about five pounds of dry solids per hour per square foot of filter surface, and the moisture content of the sludge cake will range from 70 to 85%. Vacuum filters will dewater digested, raw, activated, or partly digested sludge.

Digested sludge or activated sludge filter cake can be dehydrated in heat driers and then bagged or sold in bulk as organic fertilizer. All sludge cake can be incinerated, and there is usually sufficient heat value in the sludge to carry on the incineration process without further addition of fuel, once the incinerator has been brought to operating temperature. Sludge may be hauled to dumping grounds at sea or pumped to suitable areas at sea.

SEWER DESIGN AND CONSTRUCTION

Separate versus Combined Sewers.—Combined sewers have been used where disposal of sewage by dilution is permissible. However, as population increases the receiving waters may become so seriously polluted as to require the installation of sewage-treatment plants; then it becomes necessary to ensure that the plants have adequate capacity to treat substantial quantities of both storm water and sewage. Moreover, combined sewers may have to be made much too large for the ordinary dry-weather flow of sew-

age alone; as a result, flow velocities may be too low to prevent formation of objectionable deposits of solids in the sewer.

Against these disadvantages, combined sewerage systems have the advantage of requiring only a single conduit in each street. In addition, the quantity of domestic sewage usually is no greater than the margin of error in estimates of the quantity of storm water; therefore, the combined sewer need not be appreciably larger than a storm-water drain for the same district. Consequently, there is a substantial saving in building the single conduit instead of two.

Design.—The arrangement of a sewer system is governed by the topography of the area to be served and the relation of the point of disposal to various points in the system. Unlike water-distribution systems, which are under pressure, sewer systems must be laid out, within the limits imposed by the terrain, so that sewage can flow by gravity from the point of origin to the point of discharge. However, since economic and engineering factors control the depth to which sewers can be laid, it becomes necessary in flat terrain to provide pumping stations in the system.

Estimates must be made of the volumes of sewage and storm water, in the case of combined systems, and the pipe sizes and slopes must be such as to provide sufficient capacity to handle maximum flows and at the same time give adequate scouring velocities at minimum flows to prevent deposits. Five factors determine the amount of liquid a sewer can convey: slope or fall; cross-sectional area and shape; character of interior walls; depth of sewage; and presence or absence of obstructions such as curves, air resistance, and the like. Formulas for the mean velocity of flow are based upon the fundamental laws of fluid mechanics. Minimum velocities of design flows should be at least two feet per second and maximum velocities not over eight feet per second. The amount of sewage depends upon the water consumption of the contributing population and the amount of groundwater infiltration and storm runoff.

Sewer Pipe.—The pipe used in sewer systems is made of vitrified clay or concrete; it is usually circular in cross section, although for large combined sewers a variety of shapes may be used to meet special conditions. Clay pipe is generally used for sizes up to 42 in. in diameter and concrete pipe for larger sizes up to 108 in. Large pipe may be of reinforced concrete cast on the site.

Miscellaneous Appurtenances.—Access manholes are provided at frequent intervals to permit inspection and cleaning. In the case of drains and combined systems, catch basins at street curbs admit surface runoff and, in instances where high flow may at times exceed sewer capacity, regulating devices are provided to direct overflows to the nearest stream. Sometimes, to pass such obstacles as building foundations and rivers, sewers must be depressed for short distances; this is done in such a manner that the sewer flows under pressure, and the depressed sections are called inverted siphons. Under certain conditions special provision must be made for ventilating equipment to remove corrosive gases which may attack concrete pipe.

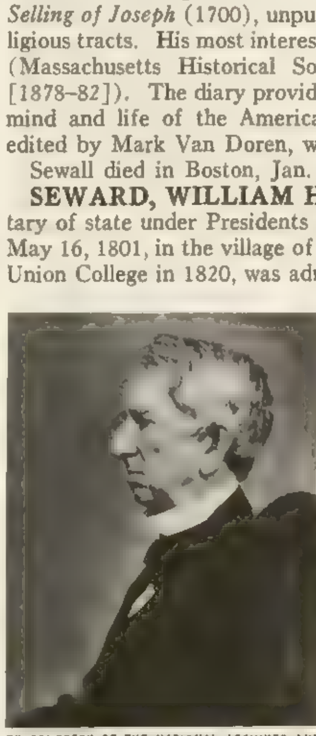
(D. E. BL.; E. S. CH.; X.)

SEWALL, SAMUEL (1652–1730), American judge of the Salem witchcraft trials, a colonial merchant and noted diarist, was born at Bishopstoke, Eng., March 28, 1652. His parents, who had previously lived in New England, returned there in 1661 and settled in Boston. After graduating from Harvard College in 1671 Sewall became a student of divinity and tutor at Harvard until he received his master's degree in 1674. A long and distinguished public career began for Sewall when he was made a "freeman" in 1679. He was manager of the colonial printing press (1681–84), member of the Council (1684–1725), and chief justice of the Superior Court (1718–28). In addition, he was a commissioner of the Society for the Propagation of the Gospel in New England, an overseer of Harvard College, captain of the Ancient and Honorable Artillery Company, and one of the special commissioners appointed to try the Salem witchcraft cases in 1692. He acknowledged, in 1697, that he had done wrong in these trials, in which 19 persons were sentenced to death.

Sewall's writings include his famous antislavery appeal *The Selling of Joseph* (1700), unpublished verses, and political and religious tracts. His most interesting and appealing work is his diary (Massachusetts Historical Society, *Collections*, 5 ser., V–VII [1878–82]). The diary provides an incomparable insight into the mind and life of the American Puritan. An abridged edition, edited by Mark Van Doren, was published in 1927.

Sewall died in Boston, Jan. 1, 1730. (RA. MU.)

SEWARD, WILLIAM HENRY (1801–1872), U.S. secretary of state under Presidents Lincoln and Johnson, was born on May 16, 1801, in the village of Florida, N.Y. He graduated from Union College in 1820, was admitted to the bar at Utica in 1822, and in 1823 began the practice of law at Auburn, which was his home for the rest of his life. Attaining distinction in his profession, he moved into politics, for which he had a greater liking, and early became associated with Thurlow Weed, then a member of the state legislature.



BY COURTESY OF THE NATIONAL ARCHIVES AND U.S. SIGNAL CORPS

W. H. SEWARD, PHOTOGRAPHED DURING THE AMERICAN CIVIL WAR BY MATHEW B. BRADY

After 1828 Seward became allied with the Antimasonic Party (*q.v.*), attending its national conventions in 1830 and 1831; as a member of this party he served in the New York senate from 1830 to 1834. By 1833, when the Antimasonic movement had run its course, he allied himself with other opponents of the Jackson Democrats and became a Whig. In 1834 he received the Whig nomination for governor of New York but was defeated by William L. Marcy. Four years later he was elected and served until 1843.

As governor, Seward favoured a policy of internal improvements, *i.e.*, building roads and canals at public expense. His administration was disturbed by antirent agitation among farmers (caused by dissatisfaction with the terms of leases) and by incidents growing out of the Canadian rebellion of 1837. During this period he attracted much attention by his liberal and humane policy; he did much to promote prison reform and proposed to admit Roman Catholic and foreign teachers into the public schools of the state. Laws were passed during his term putting obstacles in the way of recovering fugitive slaves, and Seward soon became recognized as the leader of the antislavery Whigs. He was one of the earliest political opponents of slavery, as distinguished from the radical Abolitionists who devoted themselves to moral agitation rather than to political action.

When the Whigs secured control of the state legislature in 1849 they elected Seward to the U.S. Senate where the antagonism between free labour and slave labour became the theme of many of his speeches. In his first set speech in the Senate, on March 11, 1850, he opposed the pending compromise measures (*see* COMPROMISE OF 1850) and attracted the attention of the whole country by his assertion that "there is a higher law than the constitution" regulating "our authority over the domain" (*i.e.*, the Territories). When the Democrats declared such language incendiary Seward tried to explain it away, and in so doing offended his friends without appeasing his opponents.

In the presidential election of 1852 Seward supported Gen. Winfield Scott but rejected the platform of the Whig Party because it declared the Compromise of 1850 a finality. He opposed the Kansas-Nebraska bill of 1854, which repealed the Missouri Compromise and established the principle of popular sovereignty in the Territories. As a senator he actively supported the free-state cause in Kansas. In 1854–55, when it became evident that the Whig

Party in the North was moribund, Seward helped to lead its scattered remnants into the Republican fold. As the recognized leader of this new party, his nomination by the Republicans for the presidency in 1856 and 1860 was regarded as certain; but each time he was put aside for another. The heterogeneous elements of the new organization could not be made to unite on a man who for so many years had devoted his energies to purely Whig measures, and he was considered less "available" than Frémont in 1856 and Lincoln in 1860. It was during this period, in 1858, that he referred in a speech at Rochester, N.Y., to the "irrepressible conflict" between the free and slave sections of the nation.

After Lincoln was elected in 1860 he chose Seward to be his secretary of state. The new president was a man comparatively unknown outside the state of Illinois, and many of his supporters, doubtful of his ability to deal with national problems, looked to Seward as the most experienced man of the administration and the one who should direct its policy. Seward himself apparently shared these views (not entirely out of vanity) and at first possessed an unbounded confidence in his ability to influence the president and his cabinet. He believed that the Union could be saved without a war, and that a policy of delay would prevent the secession of the border states, which in turn would gradually coax their southern neighbours back into proper relations with the federal government. He even suggested embroiling the United States in a war with England or France as a means of restoring the Union. In informal conferences with commissioners from the seceded states he assured them that Fort Sumter would be speedily evacuated. Lincoln overruled him and sent a relief expedition to Sumter without Seward's knowledge. On most issues, however, Seward remained Lincoln's closest and most influential adviser.

As secretary of state Seward rendered services of inestimable value to the nation. To prevent foreign governments from giving official recognition to the Confederacy was the task of the hour, and in this he was successful. While he did not succeed in preventing the French occupation of Mexico or the escape of the Confederate cruiser "Alabama" from England (*see* "ALABAMA" ARBITRATION), his diplomacy prepared the way for a satisfactory adjustment of the difficulties with these powers. While his treaty with Lord Lyons in 1862 for the suppression of the slave trade conceded to England the right of search to a limited extent in African and Cuban waters, he secured a similar concession for U.S. war vessels from the British government, and by his course in the "Trent" affair (*see* AMERICAN CIVIL WAR: *Politics, Economics and Foreign Affairs*) he virtually committed Great Britain to the U.S. attitude with regard to the right of search.

On April 5, 1865, Seward was accidentally thrown from his carriage and severely injured. Nine days later, while lying ill at his home in Washington, he was attacked by Lewis Powell, alias Payne, a fellow-conspirator of John Wilkes Booth, at the same time that Lincoln was assassinated. Seward's wife, an invalid, received such a shock that she died within two months, and his only daughter, who witnessed the assault, never recovered from the effects of the scene and died within the year. Seward gradually regained his health and remained in the cabinet until the expiration of President Johnson's term in 1869. In the struggle between the executive and Congress over the method of reconstructing the southern states, Seward sided with Johnson and thus shared some of the obloquy bestowed upon that unfortunate president. His greatest work during this period was the purchase of Alaska from Russia in 1867 for $7,200,000, a purchase which at that time was characterized by some as "Seward's Folly." After returning to private life, Seward spent two years in travel and died at his home in Auburn on Oct. 10, 1872.

BIBLIOGRAPHY.—The best biography of Seward is that by Frederic Bancroft, *The Life of William H. Seward*, 2 vol. (1900). *See* also G. E. Baker (ed.), *The Life and Works of William H. Seward* (1883); F. W. Seward (ed.), *William H. Seward: an Autobiography from 1801 to 1834, with a Memoir of His Life and Selections from His Letters*, 3 vol. (1877–91). (W. B. HE.)

SEWARD, a town of Alaska, U.S., at the head of Resurrection Bay, about 1,800 mi. (2,897 km.) NW of Seattle, Wash. Transportation is the chief industry. Founded in 1903 as the terminus of a railway to the Yukon Valley and named for William H. Seward, who as secretary of state negotiated for the purchase of Alaska by the U.S., Seward was chartered in 1907. In 1913 the federally owned Alaska Railroad was created and took over the railway development. The town was severely damaged by the March 1964 Alaskan earthquake and the resultant seismic waves.

The small boat harbour and airfield are used extensively by chartered hunting and fishing parties. The August silver-salmon derby is a special attraction for fishermen. Hunting is varied; moose and bear, mountain goats, small game, and birds abound. The population is approximately 2,000. (J. E. CL.)

SEWING MACHINE. The sewing machine was the first mechanical home appliance to have wide distribution and has served as a forerunner of industrial civilization in many remote areas. It remains one of the most important labour-saving devices for both industry and the home. (*See* CLOTHING MANUFACTURE; HOME EQUIPMENT: *Sewing Machines*.)

History.—The earliest recorded aid to hand sewing was the double-pointed needle with the eye at one end, patented in England by Charles F. Weisenthal in 1755. The needle was held in the middle, eliminating the need to turn it for each reentry into the fabric.

Many features of the modern sewing machine were specified in a patent secured in England by Thomas Saint in 1790, in which he described a horizontal cloth plate or table, an overhanging arm carrying a straight needle, and a spool for a continuous supply of thread. A forked needle pushed the thread through a hole made by a preceding awl, the thread being caught below by a looper and held until the needle descended again. Had Saint hit on the idea of the eye-pointed needle, his machine would have been a complete anticipation of the modern chain-stitch machine.

Early 19th-century efforts were directed toward embroidery machines. The first machine for utilitarian stitching was a chain-stitch machine, using a barbed needle and simulating a manual operation, devised and patented in 1830 by a French tailor Barthélemy Thimonnier. In 1841 Thimonnier and his associates provided 80 machines to make clothing for the French Army, but a mob of angry tailors, fearing competition, destroyed them. Thimonnier later obtained patents in England and the U.S. but gained nothing financially from either venture.

Walter Hunt of New York, about 1832–34, constructed a machine having a vibrating arm, at the extremity of which was fixed a curved needle with an eye near its point. In stitching, this needle formed a loop of thread under the cloth; another thread was passed through the loop by an oscillating shuttle, making a lockstitch. This new concept of machine sewing enabled inventors to depart from the idea that a sewing machine must imitate a hand operation.

Apparently unaware of Hunt's invention, which was never patented, Elias Howe (*q.v.*) of Spencer, Mass., invented an amazingly similar machine, which was patented in the U.S. in 1846. In both machines the fabric was held vertically by pins on a baster plate. The curved eye-pointed needle moved in an arc to a horizontal position as it entered the fabric, interlocking the needle thread with a second thread carried by a shuttle running to and fro on a track. The Howe machine could stitch straight seams the length of the baster plate, after which the fabric had to be reset.

Howe's invention was sold in England to William F. Thomas, a corset manufacturer, who in 1846 secured the English patent in his own name and engaged Howe on weekly wages to adapt the machine for his manufacturing purposes. The career of the inventor in London was unsuccessful, and, having pawned his first machine and his American patent rights, he returned in 1849 in poverty to the U.S. There, in the meantime, the sewing machine was beginning to excite public curiosity, and various inventors were making machines which Howe believed infringed on his patent rights. Among them were Charles Morey and Joseph Johnson, who used the eye-pointed needle and a hook to form the chain stitch; John Bachelder, who added an endless leather belt as a continuous feed device; and Sherburne C. Blodgett and John A. Lerow, who used a circular feeding bar that allowed continuous sewing.

The most prominent manufacturer, if not inventor, ultimately

appeared in Isaac Merrit Singer (*q.v.*), who in 1851 secured a patent for his machine, which made a lockstitch by means of a straight eye-pointed needle moving vertically and a reciprocating shuttle moving horizontally. His machine also featured a table to support the cloth, with the toothed wheel-feed protruding through the table surface. A vertical presser foot held the cloth down as the needle retracted. Alarmed by Singer's invention, Howe, having recovered his American patent rights, moved to vindicate his rights by instituting suits against the infringers of his patent. An enormous amount of litigation ensued, but in 1856 four manufacturers (including Howe) joined the "Sewing Machine Combination," whereby they agreed to pool their patent interests and pay Howe royalties, thus providing the first large-scale example of a patent pool.

Allen B. Wilson, one of the most ingenious inventors, also worked without knowledge of previous efforts. In 1849 he devised the rotary hook and bobbin combination and with the financial support of Nathaniel Wheeler obtained patents for them in 1851 and 1852, and then patented in 1854 the important and effective four-motion feed for moving the fabric after every stitch. In 1851 William O. Grover and William E. Baker, two Boston tailors, patented a double chain-stitch machine that used two threads directly from the spools.

Very few sewing machines were manufactured before 1850, yet in 1860 more than 111,000 machines were produced by 74 U.S. companies. Although thousands of patents have been issued in the U.S. and Europe for sewing machine improvements and attachments, the main principles have not been affected.

Modern Sewing Machines.—In the manufacturing industries there are more than 2,000 varieties of modern sewing machines, primarily designed for specific operations. Straight-stitch sewing machines commonly used in the home have undergone little change in the basic engineering since the early 20th century, but the use of electricity and such refinements as the hinged presser foot and the sewing light have greatly increased their popularity.

Although sewing machines are manufactured in several European countries and in the U.S., the world's largest producer is Japan. Japanese manufacturers also pioneered development of "zigzag" machines, which permit machine embroidery. Zigzag stitching is basically a lockstitch of bobbin and spool threads that zigzag as the threaded needle shifts from side to side. Manufacturers in other countries produced models of zigzag machines and straight-stitch machines with zigzag attachments. (G. R. Co.)

SEX, the sum of the features by which organisms exhibit a complementary difference, recognized in higher plants and animals as maleness or femaleness.

Beginning with mechanisms for ensuring occasional genetic recombination in primitive microorganisms, sex has undergone an evolution of its own throughout the whole history of life on earth. Elaborate patterns of behaviour, strange and complex structures, and delicate physiological equilibriums have all been developed under the influence of natural selection, ensuring the continued existence of species with an abundant supply of new combinations of genes in each generation.

This article is concerned strictly with the biological aspects of sex. Helpful background information can be found in REPRODUCTION, which is concerned with, among other things, the evolution of sex. For the anatomy and physiology of the human sex organs, *see* REPRODUCTIVE SYSTEM. For details of the fusion of gametes, *see* FERTILIZATION. The following sections constitute this article:

I. TYPES OF SEXUALITY

Although structural differences between male and female are not always apparent, as in many lower organisms, functional differences can always be distinguished. In the majority of organisms above the level of complexity of viruses and bacteria, a new individual is brought into being by the cooperation of a male and a female organism, each of whom contributes a special cell, a gamete or sex cell, toward that creation: the male donates a spermatozoon, or sperm; the female, an ovum, or egg. The affinity that sperm and egg have for each other may result in their fusion (fertilization). The single-celled product, a zygote, carries its own blueprint for development derived from each of its parents.

Sexuality is not always an either-or determination. Organisms exist that produce both sperms and eggs; these, called hermaphrodites, occur naturally in many groups of lower animals and in most groups of higher plants. Among fungi and protozoa, sex is often found in more than two genetic forms, which are referred to as mating types. In higher animals and plants, intersexes, gynandromorphs, and sexual mosaics are not uncommon; the occurrence of such intergraded forms reflects the range of possibilities that may proceed from variable action of genetic endowment and hormonal influence.

A. ANIMAL

1. Sex Cells.—The condition in which the gametes are equal in size and shape, as in some protozoa, algae, and fungi, is termed isogamy. It is a phenomenon that occurs only at the morphological level, for regardless of appearance the gametes exist in different functional forms of a complementary nature. In the higher animals anisogamy is the rule; the gametes are regularly of two kinds. The egg is in most cases a very large nonmotile cell containing considerable food reserves in the form of yolk or other substances that contribute to the development of the embryo. The sperm is a relatively small cell that swims by means of a tail or flagellum. Some exceptions exist, such as motile amoebalike ova in sponges and tailless sperms in various groups of invertebrate animals (*e.g.*, nematode worms, crabs, and lobsters).

Usually, the number of sperms produced is vastly in excess of the number of eggs, the ratio often being millions to one. Such an arrangement maximizes the probability that the egg will be fertilized and, because the sperms are so small and lack specialized food reserves, this is done with biochemical economy.

2. Bisexuality.—In most higher animals the sperms and eggs are produced by males and females, respectively. The sexes are distinguished by primary sex characters, the ovaries or testes and their ducts, and may also show secondary sex characters such as the comb and wattles in cocks, beard in man, etc. The extent of obvious sex differences (sexual dimorphism) depends on the degree of development of secondary sex characters. At one end of the scale are species in which the sexes are not distinguishable externally (certain beetles, some birds), while at the other end are forms in which there is so little resemblance between the sexes that, in some instances, they were originally described as distinct species. In the extreme case of certain marine worms and deep-sea angler fishes, the male is a relatively minute individual that lives a parasitic existence on or in the much larger female.

3. Hermaphroditism.—In an earthworm or a land snail, ova and sperms are produced by the same individual, which is re-

ferred to as monoecious or hermaphroditic. Copulation usually occurs between two different individuals, and fusion of their ova and spermatozoa gives rise to zygotes that develop into the individuals of the next generation. Obviously, however, there exists in such cases a possibility that self-fertilization may occur; *i.e.*, that the ova and spermatozoa produced by a single individual may fuse. Self-fertilization does in fact happen in a number of species of plants and animals. There are, however, various anatomical, physiological, or genetic mechanisms that may limit self-fertilization or prevent it altogether in particular species. One of these is consecutive hermaphroditism, in which the individual produces sperms and eggs at different times in its life cycle. Periodic sex reversal of this kind is widespread in marine mollusks such as oysters and slipper limpets.

Hermaphroditism is found in almost all flatworms, including the free-living planarians and the parasitic flukes and tapeworms (but with a few exceptions such as the blood-inhabiting *Schistosoma* or *Bilharzia* flukes, which are bisexual); in earthworms and leeches; and in land and freshwater mollusks. In the arthropods, including insects, hermaphroditism is only very rarely encountered. It does occur, however, in the scale insect *Icerya purchasi*, a pest of citrus trees in many countries. In the vertebrates bisexuality is almost universal, but a few species of fishes may show consecutive hermaphroditism. (*See* also HERMAPHRODITE.)

4. Variations in Sexual Behaviour.—In all higher vertebrates psychological stimuli seem to play a part in the control of anterior pituitary activity, which in turn determines the activity of the sex organs, or gonads. There is thus a very complex chain of relationships with "feedback" mechanisms of several kinds (*e.g.*, the gonadal hormones tend to depress pituitary activity). This elaborate series of highly labile physiological mechanisms is developed in each individual as a result of genetic equilibria involving several complexes of genes on the sex chromosomes and the autosomes; it is therefore not surprising that sexual behaviour should be highly variable. In the human species, where it is undoubtedly modified and influenced by psychological factors to an even greater degree than in other higher vertebrates, sexual behaviour is especially variable.

To distinguish between "normal" and "abnormal" behaviour is almost meaningless, except insofar as the term "normal" may be used to designate a statistical average. The strength of the sex drive in both sexes of the human species exhibits an extreme range, from very low to very powerful activity, and this primary sex drive tends to be associated with other creative activities and outlets. The human sex drive may be concentrated entirely on individuals of the opposite sex, but not infrequently it may be directed toward individuals of the same sex (homosexuality; *q.v.*).

Many mammals exhibit occasional homosexual behaviour and in some species it may be manifested quite regularly; *e.g.*, in the giraffe. In the human species, the frequency of homosexual activity and its relation to heterosexual behaviour vary greatly from one culture to another: thus the Siriono of eastern Bolivia are said to hardly ever engage in homosexual practices, while among the Arunta (Aranda) of central Australia almost all the men are reported to practise homosexuality to some extent. According to A. C. Kinsey and his collaborators, about 10% of U.S. males had shown exclusively or mainly homosexual behaviour for three years or more prior to interview. The incidence of a comparable degree of homosexuality among women (lesbianism; *q.v.*) is believed to be only about 1%. F. J. Kallmann's data on homosexuality in monozygotic (identical) and dizygotic (nonidentical) twin pairs strongly suggest that genetic factors play a considerable role in the determination of homosexuality. If homosexuals, who have few or no children through heterosexual alliances, do not transmit any genes to future generations, why has homosexuality not disappeared? A possible explanation (which, if at all valid, is only part of the answer) may be that a portion of the heterosexual population bears the genes for homosexuality in a masked, hybrid state and thus continues to replenish the homosexual population. There is little evidence of gross hormonal imbalance in homosexuals, as was earlier believed.

See SEXUAL BEHAVIOUR; SEXUAL DEVIATIONS.

B. PLANT

Sexual differentiation in the higher plants is essentially different from that in animals, although the final result is similar. The individual plant is a sporophyte or spore producer.

1. Spores.—There are two kinds of spores, large megaspores and small microspores or pollen grains. Unlike gametes, these spores do not undergo direct fusion; instead, they develop, within the pistil of the flower, into microscopic individuals known as gametophytes, the pollen grain forming the male gametophyte and the megaspore the female gametophyte. The gametophytes each produce a gamete and the two gametes fuse and give rise to a sporophyte, thus completing the life cycle. The seed in a flowering plant is simply an embryo sporophyte, its development temporarily arrested, together with nutritive materials and a protective coat.

2. Sexual Variation.—In most species of higher plants the sporophyte is monoecious or hermaphroditic; *i.e.*, it produces both ovules and pollen grains. But in such plants as hop, hemp, date palm, papaya, and sorrel dock (to name only a few), two kinds of individual sporophytes exist, which may be called males (producing only pollen) and females (ovule producing). Plants like this are said to be dioecious. In some other cases the sporophyte is hermaphroditic, but the pollen and ovules are borne on different kinds of flowers (*e.g.*, in maize, melon, and cucumber).

In certain plants, such as primrose, different kinds of individuals may exist ("pin" with long style and short stamens and "thrum" with long stamens and short style), and the system may be such that under natural conditions pin cannot pollinate pin or thrum fertilize thrum. But this is not really sexual dimorphism since the two kinds of sporophytes each produce both ovules and pollen grains; it is, however, a phenomenon analogous to sexual differentiation. Many species of plants possess mechanisms of self-sterility without any visible difference between kinds of individuals, such as exist in the primroses. And, on the other hand, there are some plant species, such as cultivated wheat, in which self-fertilization almost always occurs and cross-fertilization is a rare accident. *See* PLANTS AND PLANT SCIENCE: *Morphology of Plants*.

II. VALUE OF SEX

Typically, the zygote or fertilized egg contains a double or diploid set of chromosomes in its nucleus, each chromosome being represented twice. The individual that develops from the zygote likewise has two sets of chromosomes in every cell. During the formation of the gametes (in animals) or of the spores (in plants) a reductional process called meiosis occurs, whereby the chromosome number is halved. Thus gametes and spores contain only a single or haploid set of chromosomes. The diploid number is restored at fertilization by the fusion of two haploid nuclei.

In the higher plants, with their characteristic alternation of sporophyte and gametophyte generations, the sporophyte is typically diploid, the gametophyte haploid. In ferns the conspicuous leafy sporophyte is likewise diploid, the inconspicuous but free-living hermaphroditic gametophyte, haploid. In the mosses, the familiar plant is the haploid gametophyte, which is monoecious in some species and dioecious in others, the diploid sporophyte being small and parasitic on the gametophyte. In both mosses and ferns the sperms are flagellated and swim to the egg.

In many algae and fungi meiosis occurs immediately after fertilization, so that the zygote is the only diploid cell in the life cycle.

1. Genetic Significance.—In sexual reproduction every individual receives a set of chromosomes from each of two parents and passes on mixtures of these chromosomes to its offspring. Thus, in each generation the genetic material is recombined in new ways. Actually, the "shuffling" of the hereditary determinants, or genes, is even more thorough than the above oversimplified statement would indicate, since during meiosis a process of crossing over between the maternal and paternal chromosomes takes place, which leads to the formation of chromosomes containing some genes of maternal origin and others of

paternal origin. The number of genes is so great that in a sexually reproducing population of higher organisms no two individuals are precisely alike, all having unique combinations of genes that will not recur in populations of even many trillions of individuals.

The uniqueness of the individual is thus a consequence of sexual reproduction. The significance of sex can be fully appreciated only if the instances in which it has been lost in the course of evolution are considered. There exist numerous species of animals and plants in which the egg regularly develops into an embryo without having been fertilized—a phenomenon known as parthenogenesis (*q.v.*). Obviously in such cases sperms are superfluous and, in fact, males may be entirely lacking from the population, so that the species consists exclusively of females. In species of this kind the chromosome number is not halved by meiosis during the formation of the egg, or, if it is halved, a compensatory doubling takes place to maintain the chromosome number constant from one generation to the next. In such parthenogenetic species all the progeny of a female, in general, carry exactly the same genes as their mother and in consequence resemble one another and their parent almost exactly, like the so-called identical twins in the human species, which owe their origin to a nonsexual form of reproduction in which the zygote divides vegetatively to produce two embryos (*see* MULTIPLE BIRTHS).

2. Biological Diversity.—The great biological diversity characteristic of sexually reproducing species is thus not found in parthenogenetic forms, and the adaptive genetic qualities of the two different parents can never be combined in their offspring in a nonsexual genetic system. In parthenogenetic species, natural selection, the force that has molded the whole evolution of life, lacks the constructive and creative properties it possesses in sexual species. It is not surprising, therefore, that asexual forms of reproduction, including both parthenogenesis and asexual reproduction by simple fission, budding, runners, bulbs, etc., seem to have been relatively unsuccessful in evolution, except as accessory mechanisms. They may permit the rapid multiplication of individuals on a large scale, but at the expense of evolutionary adaptability, so that every asexual species is in a "blind alley." Sooner or later its uniformity and lack of plasticity and adaptability will lead to extinction.

Sex is certainly not necessary for reproduction, and many species of animals and plants seem to get on quite well without it, but it is surely essential for long-term evolutionary success. From this standpoint there is not much difference between unisexual (hermaphroditic) and bisexual reproduction. What is important is the fusion of genetically unlike gametes; whether they are produced by separate male and female individuals is of secondary importance. Even in bacteria and viruses, which were formerly believed to be strictly asexual, it has been known since 1946 that various kinds of phenomena analogous to sex occur, which result in bringing together in one individual genetic materials derived from two different ones. The occurrence of this system in such primitive organisms indicates that sexual processes may have existed from the earliest period of life on earth.

In various groups of organisms, some kind of compromise between sexual and nonsexual forms of reproduction is found. Thus the typical life cycle of aphids consists of a number of parthenogenetic summer generations, followed by a single bisexual winter generation. The parthenogenetic generations permit very rapid multiplication of individuals under favourable conditions, while the sexual generation produces new combinations of genes once a year, upon which natural selection can operate. A different kind of compromise between sex and parthenogenesis exists in certain insects such as wasps, ants, and bees. In these, the sex of the individual depends upon whether it has developed from a fertilized or from an unfertilized egg. In the former case a female results, while in the latter a male is produced. Females thus have two parents (but only three grandparents), while males have a mother, but no father. In these insects the members of the "worker" caste come from fertilized eggs, show some female secondary sex characters, and are essentially females whose ovaries have remained in a rudimentary condition. In termites, on the other hand, the "worker" caste seems to consist of both sterile males and sterile females.

In some forms of parthenogenesis, sperms as well as eggs are produced, and copulation occurs, the sperms being even necessary for triggering off the development of the egg although they do not contribute any chromosomes to it. This type of reproduction, known as pseudogamy, occurs in some earthworms, where it has clearly been derived from the usual hermaphroditism of the group in the course of evolution. An analogous process is also known in some plants. Pseudogamy also exists in a small Mexican freshwater fish, the Amazon molly (*Mollienisia formosa*), a species that consists exclusively of females whose eggs have to be stimulated to develop by the sperms of two closely related species; the developing embryos of *M. formosa* do not inherit any of the characteristics of the pseudo fathers.

III. SEX DETERMINATION

1. Chromosomal Mechanism.—In the great majority of bisexual organisms some kind of genetic mechanism of sex determination is operative, causing certain zygotes to develop into males, others into females. The "switch" mechanism that controls the direction of development consists in most cases of a special pair of sex chromosomes, present in all the cells of the body. In one sex the two sex chromosomes are alike in size and shape (*i.e.*, are homogametic) and are known as X chromosomes. In the other, or heterogametic sex, there is a pair consisting of an X chromosome and a chromosome that differs from it genetically (and sometimes also in size and shape), known as a Y chromosome. Chromosomes other than the sex chromosomes are known collectively as autosomes. The gametes produced by the homogametic sex all carry an X, while those produced by the heterogametic sex are of two kinds, bearing X and Y chromosomes respectively. Thus at fertilization (if the X- and Y-bearing gametes are equally likely to take part in fertilization, which is probably only approximately true) equal numbers of XX and XY zygotes will be produced.

In most groups of animals and in the majority of those higher plants that are dioecious, it is the male sex that is heterogametic, so that there are two kinds of sperms, or pollen grains, and only one kind of egg, or megaspore. But in certain fishes and amphibians and in all birds, all lepidopterans, and all caddis flies, the situation is reversed: the female is heterogametic and the male homogametic, so that there are two kinds of eggs and only one kind of sperm. Some authors speak of Z and W chromosomes instead of the usual X and Y terminology, to distinguish the species with female heterogamety. Usually, the X and Y chromosomes are visibly different in size or shape, when examined under the microscope, but in certain fishes and amphibians there is convincing evidence, from breeding experiments, that X and Y chromosomes exist in spite of the fact that they cannot be distinguished from one another or from the remaining chromosomes under the microscope. In some other groups the genetic evidence is still lacking, so that in the absence of cytologically distinguishable sex chromosomes it is not certain which sex is heterogametic (this is the situation with regard to some reptiles).

Before proceeding to discuss how the switch mechanism of sex determination actually works, two further types of systems may be mentioned that have arisen as evolutionary derivatives of the XY-XX type. (1) In certain animal species the Y chromosome is altogether absent, so that the diploid number in the heterogametic sex is an uneven one, the X being without a mate. This is the case in most grasshoppers, crickets, roaches, dragonflies, and in many species of beetles and nematode worms (all groups with male heterogamety). In such forms, the heterogametic sex may be called XO in constitution, where O represents simply the absence of a chromosome. (2) In certain other species of animals and in some dioecious plants, sex chromosome mechanisms are found in which the X or the Y is represented by several chromosomes (X_1, X_2, X_3 . . . , or Y_1, Y_2, Y_3 . . .). Most of the larger green species of praying mantises are X_1X_2Y in the

male and $X_1X_1X_2X_2$ in the female (while the smaller species and some larger ones have XO males and XX females). Most species of spiders have X_1X_2O males and $X_1X_1X_2X_2$ females, while four species of mammals, including the common European shrew (*Sorex araneus*) and the Tasmanian rat kangaroo, or potoroo, are known to have XY_1Y_2 males and XX females. In all these instances, the several X or Y chromosomes are inherited as a group, so that, for example, the X_1X_2Y praying mantises produce sperms with both an X_1 and an X_2 chromosome and sperms with a Y but no X. The eggs of the same species carry both an X_1 and an X_2.

There appear to be at least two basically different genetic mechanisms of sex determination. In species with a Y chromosome, this element may determine the characters of the heterogametic sex. This seems to be the case in the human species, where the diploid number is known to be 46 in both sexes (22 pairs of autosomes and a pair of Xs in the female, the same autosomes plus an X and a Y in the male). Persons who possess two Xs and a Y exhibit a type of intersexuality known as Klinefelter's syndrome. They may be regarded as individuals that would have been females if they had not possessed the extra Y chromosome that masculinized them to some extent—or as individuals that would have been normal males had they not been feminized by an additional X. Persons with 45 chromosomes who are XO in constitution are sterile females exhibiting ovarian dysgenesis (Turner's syndrome). The conclusion to be drawn from this work on abnormal sex chromosome situations in the human species is that the Y is actively male determining and the X female determining. Obviously one X cannot do the work of two—otherwise the 45-chromosome individuals would be normal females—and it seems fairly certain that the remaining chromosomes (the autosomes) are, on balance, male determining. Normal sexual development in the human species thus depends on an equilibrium between X chromosomes and autosomes in the female and between the X, the Y, and the autosomes in the male. With such a complex genetic basis it is perhaps not surprising that there should be a wide range in the type and degree of expression of sex behaviour in the human species.

Mammalian species in general have XY males, so that the same kind of genetic sex-determining mechanism as in man may exist throughout the whole class.

In the fruit fly *Drosophila*, a different kind of system operates. The Y chromosome, although present in the normal male, is not actively sex determining, since experimentally obtained XO individuals are entirely male in appearance. However, the Y does carry some genetic factors needed to ensure male fertility, since such XO flies do not form motile sperms and are hence sterile. *Drosophila* females that carry one or two Ys in addition to the normal chromosome set are not masculinized in any way. Since individuals with three sets of autosomes (instead of the usual two sets) and two Xs are intersexual, it may be concluded that sex in *Drosophila* depends on a balance between male-determining genes in the autosomes and female-determining genes in the X chromosome. Two Xs are sufficient to override the male-determining effect of two sets of autosomes, so that a normal female results, but they are incapable of completely overriding the effect of three sets of autosomes. YY individuals of *Drosophila* or mammals, which entirely lack X chromosomes, have never been obtained and are presumably nonviable.

In the Mexican axolotl, sex determination takes place in a manner closer to the mammalian type; but in this amphibian, the female is the heterogametic sex (XY), so that the role of the sex chromosomes is reversed. Some females were experimentally transformed by R. R. Humphrey into males by implanting testes of another species at an early developmental stage. Such implanted testes do not become genetically functional, but they produce male sex hormone, which masculinizes the XY (*i.e.*, genetically female) host tissues. The offspring of the mating between normal XY females and the sex-reversed salamanders consist of three kinds of individuals in a Mendelian ratio 1 XX : 2 XY : 1 YY. The XX individuals are males, the XY and YY ones are females (in this case the YY constitution is not lethal). XY and YY females cannot be distinguished externally, but when a YY female is mated with a normal XX male all the progeny are XY females. It may be concluded from this experiment that axolotls carrying one or more Y chromosomes are female and those lacking a Y are in all cases male. It should be pointed out that the X and Y chromosomes of the axolotl are not cytologically distinguishable; the interpretation is based on genetic evidence alone. In the human species, mouse, and *Drosophila*, direct cytological observation of X and Y chromosomes can be used to check the genetical interpretation.

In all the above instances the sex of the zygote is determined at fertilization by a genetic mechanism involving special sex chromosomes. There exist, however, a few species of animals with mechanisms of sex determination that seem to depend on factors in the egg cytoplasm rather than on nuclear genes. It was shown by E. Korschelt that the little marine worm *Dinophilus apatris* lays large and small eggs in the same cocoon and that the large eggs develop into females, the small into males. There is no evidence of sex chromosomes in this species, and the determination of the amount of egg cytoplasm takes place long before the meiotic divisions occur. Another animal that lays two kinds of eggs is the scale insect *Pseudaulacaspis pentagona*, in which the fertilized females first lay eggs containing coral-coloured female embryos and later eggs containing whitish male embryos; the most probable interpretation seems to be a nonchromosomal mechanism of sex determination. A similar state of affairs may exist in other scale insects: in *Stictococcus*, for example, eggs whose cytoplasm is invaded by a symbiotic microorganism give rise to females while eggs not invaded develop into males.

Sex chromosomes are, of course, absent in species of animals and plants that are normally hermaphroditic, early accounts of X and Y chromosomes in such forms as land snails being based on erroneous observations. The ovarian and testicular tissues of such animals arise by processes of histological differentiation analogous to those that produce different somatic tissues such as liver and kidney.

Genes borne on the sex chromosomes are inherited in special sex-linked ways. In the human species a gene on the Y is transmitted by a father to all his sons, but to none of his daughters. There is no certain instance of this so-called holandric ("completely masculine") inheritance in man, various supposed examples having been shown by C. Stern to rest on doubtful or erroneous records. Genes borne on the X chromosome in the human species include the well-known ones for hemophilia and colour blindness. (*See* GENETICS, HUMAN.)

2. Endocrine Mechanism.—In the vertebrates the primary switch mechanism consists of the sex chromosomes, which determine whether the individual will develop with an ovary or with a testis. These organs (or, rather, certain cell types within them) together with some other tissues such as the adrenal cortex secrete into the bloodstream steroid male- and female-determining hormones that influence the development of the secondary sex characters and the whole pattern of sex behaviour of the individual.

In mammals and birds the main androgen (male hormone) is testosterone. The site of production of testosterone in the male is the so-called interstitial tissue of the testis; other androgens are formed in the adrenal cortex. Castration of the male thus reduces the amount of androgen in the bloodstream but there is still a quantity left. If carried out in childhood the operation leads to eunuchism, a condition in which the appearance of the male secondary sex characters at puberty is more or less suppressed. The physiological independence of the interstitial (endocrine) and spermatogenetic tissue in the testis can be proved by the operation of vasectomy (cutting and ligaturing the *vasa deferentia* or sperm ducts): this leads to sterility, since there is regression of the spermatogenetic tissue and in any case the sperms could not pass down the duct, but the production of testosterone by the interstitial tissue is not diminished, so that the secondary sex characters and sex behaviour are unaffected.

There are a number of female hormones or estrogens, which are closely related chemically to testosterone. Although andro-

gens and estrogens act antagonistically in controlling the sexual dimorphism of the vertebrates, it is important to realize that they are not restricted to one sex only; *i.e.*, in mammals the testis probably secretes estrogen as well as androgens and the ovary produces a certain amount of androgen in addition to estrogen. Thus the hormonal difference between the sexes is merely a matter of degree. The not infrequent appearance of male secondary sex characters (*e.g.*, facial hair) in women is an evidence of minor shifting of the equilibrium between androgen and estrogen production, the cause of the abnormality being most often an overactive adrenal cortex.

The development and physiological activity of both the testis and the ovary in the higher vertebrates are under the control of the gonadotrophic hormones, secreted into the bloodstream by the anterior lobe of the pituitary body, an endocrine body on the ventral side of the brain. These hormones, of which there are several, promote the growth of the ovarian follicles and of the germinal epithelium in the testis. They are apparently the same in the two sexes and their action is to bring about the maturation and activity of the ovary or testis. Unlike the sex hormones, which are relatively simple steroid molecules, the gonadotrophic hormones are complex proteins. Two main types have been studied: follicle-stimulating hormone (FSH) and luteinizing hormone or interstitial cell-stimulating hormone (LH or ICSH). The relation between the activity of the gonads and that of the pituitary is to some extent a reciprocal one, since the sex hormones have an inhibiting effect on the formation of gonadotrophins by the pituitary. Castration may thus result in an abnormally large production by the pituitary of LH and FSH, which are excreted in large amounts in the urine. The rate of secretion of the pituitary is under neurohormonal control mediated through the hypothalamus.

Both male and female sex hormones seem to stimulate cell division, not only in the gonads and accessory sexual organs but also in other tissues, including the epidermis and intestinal lining. However, male organs such as the penis, sperm ducts, seminal vesicles, and various glands producing accessory secretions are especially responsive to androgens, while the corresponding female organs react more readily to estrogens. The sexual development of an individual is hence a complex equilibrium in which not only the relative amounts of male and female hormones but also the presence of tissues and organs differentially reactive to them is involved. *See* ENDOCRINOLOGY.

IV. SEX REVERSAL AND INTERSEXUALITY

1. Hormonal Agency.—By shifting the balance between androgens and estrogens the sexual status of the individual can be more or less profoundly modified in the vertebrates. A partial change may produce an intersexual condition, while a more radical one may lead to complete functional sex reversal in some cases.

One of the classic examples of hormonal intersexuality is the phenomenon of bovine "freemartinism." Twins in cattle may consist of two males, two females, or a male and an intersexual calf known as a freemartin. In the freemartin, the external genitalia are mainly female in type, although the internal reproductive system is generally malelike and testes may be present. It is known that the embryonic membranes (chorion and allantois) of cattle twins become partially fused in development. This permits the sex hormones of one twin to flow into the bloodstream of the other and also allows for an actual exchange of embryonic cells, which become permanently established in the co-twin. Thus all twin calves are chimeras—they contain cells derived from two separate zygotes. It has generally been supposed that freemartin calves are genetic females more or less masculinized as a result of androgens derived from the male co-twin. It is possible, however, that this is not the whole story, and that the presence in them of some genetically male (*i.e.*, XY) cells may have something to do with the development of this very characteristic type of intersexuality.

Intersexuality or sex reversal in birds may arise differently. In the female of most bird species, what is called the ovary is simply the gonad of the left side, the organ of the right side remaining in a rudimentary condition throughout life. However, upon destruction of the ovary by disease or after its removal by surgery, the right gonad may regenerate and develop into an organ that is testicular in character. The individual may, under these circumstances, undergo a more or less complete sex reversal, acquiring male plumage, wattles, and behaviour. There is one case on record of a chicken that had reputedly been the mother of many offspring before she suffered avian tuberculosis; the disease destroyed the ovary, and the chicken underwent sex reversal and eventually became a fertile rooster and fathered two chickens.

2. Genetic Agency.—Although the above instances of intersexuality are hormonal rather than genetic in origin (if the traditional interpretation of freemartinism is accepted), genetic intersexuality is quite a well-known phenomenon. Two types of human intersexuality which are due to unusual sex chromosome combinations have already been referred to (see *Chromosomal Mechanism*, above). In insects, however, many instances are known where single gene mutations lead to the production of intersexuality or even (in the case of the transformer gene in *Drosophila*) to the complete transformation of one sex into the other.

One of the most thoroughly studied cases of genetic intersexuality is that of the offspring of certain interracial crosses in the gypsy moth (*Porthetria dispar*). Here the strength of the genes determining maleness and femaleness varies from one geographic race to another. Within each race the two are in balance, so that only normal males and females are produced, but in laboratory-bred hybrids between different races, various types of unbalance may lead to intersexuality or sex reversal. Genetic intersexuality seems to exist also in certain vertebrates, such as the pigs of the New Hebrides.

No circulating sex hormones seem to exist in insects. Thus the removal of the testis or ovary from a young caterpillar or other insect larva, even if followed by implantation of gonads of the opposite sex, does not lead to any modification of the secondary sex characters and the adult that develops from such a larva, although sterile, still acquires the sex characters and behaviour that correspond to its original chromosomal constitution. The intersexes that have been described in insects are thus, in general, all of genetic rather than hormonal origin. In the wasp *Habrobracon* the male normally arises from an unfertilized egg and has only a single set of chromosomes. Such males carry any one of nine or more genetic sex factors (x_1, x_2, x_3 . . .). Females arise from fertilized eggs (*i.e.*, they have two chromosome sets) and carry two different sex factors (*e.g.*, x_1 x_2, x_5 x_7 . . .). By inbreeding, one can obtain individuals with two chromosome sets that carry two identical sex factors (x_1x_1, x_2x_2 . . .). These are sterile "biparental" males. Thus femaleness depends on some kind of interaction between different x factors in the same cell. It is also possible to obtain, in special genetic experiments, individuals of *Habrobracon* that have arisen from binucleate eggs. Some of these individuals have no more than a single set of chromosomes in any of their cells, but they carry different x factors on the right and left sides of the body. Such individuals would be expected to be males, but in fact they have a streak of feminized tissue down the middle, along the meeting ground of the two kinds of tissue. Thus some local cell-to-cell diffusion of sex-determining substances produced by the x factors seems to take place.

3. Parasitism.—Another phenomenon that modifies secondary sex characters (amounting in some instances to conditions similar to true intersexuality) may result from infection by parasites. This phenomenon, which occurs in crustaceans and insects, has been called parasitic castration, since it is usually accompanied by some degree of degeneration or destruction of the gonad, resulting in sterility.

Four examples may be cited. (1) Certain species of crabs are liable to infestation by parasitic barnacles (*Sacculina, Thompsonia*), degenerate crustaceans whose bodies are reduced to a saclike mass with a branching system of rootlike processes that

penetrate the tissues of the host. Male crabs so infested may become partly feminized in their external features, as their claws become relatively smaller, their abdomens narrower, and hairs develop on the swimmerets (to which, in a true female, eggs would be attached). Infested female crabs, on the other hand, are masculinized only to a slight extent, or not at all. (2) Males of some species of bees, wasps, and leafhoppers are similarly affected when parasitized by insects belonging to the order Strepsiptera, a phenomenon which has been called stylopization, from the name of the principal genus of these parasites, *Stylops*. (3) Males of certain species of grasshoppers may fail to acquire male secondary sex characters and may undergo a certain degree of feminization following parasitization by certain nematode worms (Mermithidae). (4) In certain chironomid midges a similar change, but in this case from femaleness to maleness, may likewise be caused by mermithids. The changes in the secondary sex characters in all these instances are probably due to profound changes in the general metabolic pattern produced by parasitization rather than to any specific action of sex hormones.

4. Gynandromorphism.—In all multicellular organisms it is possible to obtain, from time to time, abnormal individuals whose chromosomal constitution is different in different parts of the body. Such monstrosities are referred to as genetic mosaics. The most clear-cut genetic mosaics are found among the types called gynandromorphs, individuals having part of the body chromosomally male, the remainder chromosomally female. Gynandromorphs have been studied extensively among the insects and spiders, in which there are no circulating sex hormones to mask the expression of the genetic constitution of certain tissues. In many other groups of invertebrates with clear sexual dimorphism, gynandromorphs seem not to be known. Where one side of the body is male, the other female, there is a bilateral gynandromorph; where the dividing line between the two regions is transverse there is an anteroposterior one. In many instances, however, the distribution of the male and female parts is more irregular. In fruit flies of the genus *Drosophila*, gynandromorphs arise mainly by loss of one X chromosome from one of the two daughter nuclei at the first cleavage division in the zygote. In other insects they may arise in different ways; *e.g.*, in moths from binucleate eggs, one nucleus carrying an X, the other a Y. In bees and other Hymenoptera, gynandromorphs may likewise arise from binucleate eggs, one nucleus being fertilized by a sperm while the other remains unfertilized and gives rise to male tissue.

In all these cases the dividing line between the male and female parts is a sharp frontier; there are no tissues or regions that show an intermediate expression of the secondary sex characters. Gynandromorphs may exist but be unrecognizable as such in the vertebrates, where the circulating sex hormones would inevitably blur the sharpness of the frontier between the genetically male and female tissues and would probably lead to a condition indistinguishable from genetic or hormonal intersexuality. *See* also GYNANDROMORPH.

V. SEXUAL CYCLES

1. Periods.—Almost all animals and plants go through cycles of development, somatic growth, sexual activity, and reproduction. In many organisms death may follow closely on the single sexual cycle, while in others there may be a long series of cycles, recurring at more or less regular intervals. Annual plants have a single sexual season, perennial ones usually have annually recurring flowering periods, while certain desert agaves increase in size for many years before they put up a reproductive spike, after which the whole plant dies.

In most animals the reproductive cycle is related to the seasons. This is most obvious in temperate climates, but seasonal cycles occur even on the Equator. The reproductive cycles of many species of birds are controlled by the length of the day, so that in temperate regions sexual behaviour (courtship, nest building, etc.) is initiated when a certain critical day length is reached (usually in spring, but sometimes in the fall). In desert regions, however, rainfall may be the initiating stimulus. Some reproductive cycles of marine organisms are related to the phases of the moon: the Pacific palolo worm spawns only in October and November; at daybreak on the day when the moon enters the last quarter the sea may become milky white with the eggs and sperms. Moonlight is also known to control the time of spawning of many mollusks.

In mammals, the mature females pass through a series of estrous cycles in the course of the year and will only mate and become pregnant during the period of estrus, or "heat." If pregnancy occurs, the sequence of estrous cycles is interrupted and is usually resumed after the termination of the subsequent lactation period. In the higher primates a modified type of estrous cycle, the menstrual cycle, occurs. It differs from the more typical mammalian cycle in two ways: the female will generally mate throughout the cycle instead of only at a sharply defined period of "heat" and at a certain stage in the cycle there is a pronounced vaginal bleeding (menstruation), due to breakdown of the lining of the uterus.

The timing of both the seasonal and estrous cycles is undoubtedly under the control of the anterior pituitary, but the details of the control mechanisms are not fully understood. As far as the seasonal cycles are concerned, it is clear that visual stimuli play a major role in triggering off pituitary activity in many species.

2. Courtship.—More or less elaborate and stereotyped patterns of courtship behaviour occur in many groups of animals. They are usually highly species-specific, thereby preventing or strongly discouraging the mating of different but related species. However, in the fruit flies of the genus *Drosophila*, H. T. Spieth (1952) noted that closely related species seem to display identical mating behaviour (*i.e.*, identical to the human observer; it might not appear identical to another *Drosophila* or to a human observer equipped with special recording instruments).

In moths the males of certain species are attracted to the females over very considerable distances by minute amounts of special chemical substances carried as aerosols. In some other groups of insects, such as grasshoppers, crickets, and cicadas, sound may play a major part in bringing the sexes together; the same is true of course, in certain vertebrate groups such as the frogs. Some of the more specialized types of courtship or precopulation behaviour in insects may involve the presentation of a special food morsel to the female, which is eaten by her as part of the sexual ritual.

Courtship behaviour can be quite elaborate in some fishes (sticklebacks, swordtails) and in many birds (ruffs, grebes, bowerbirds). In the higher vertebrates, not only sexual activity but many other forms of behaviour are under the control of the gonadal sex hormones. Sexual display, nest building, territorial defense, etc., may all be induced in immature or castrated males by injection of testosterone. Testosterone seems to be responsible for aggressive behaviour and social dominance in both sexes in birds. In a flock of chickens the "peck order" is determined by the testosterone levels of the individual birds, and hens injected with testosterone undergo a dramatic increase in their social status in the flock. In general, female sex hormones injected into males produce very little physiological effect, either in birds or in mammals. (*See* COURTSHIP, ANIMAL.)

3. Insemination.—The sperm is almost always a delicate cell which requires a fluid medium in which to swim and which is readily killed by desiccation. In a great many marine and freshwater organisms the seminal fluid is simply shed into the water by the male, in close proximity to the eggs. The success of fertilization is ensured, partly by the enormous number of sperm and partly by the fact that they are chemotactically attracted toward the eggs by special secretions. This is external fertilization, which obviously cannot occur in strictly terrestrial animals. Internal fertilization, generally characteristic of land animals, involves copulation and the deposition of the male gametes within the genital tract of the female; it occurs also in some marine animals such as sharks and rays, where the mature egg has a hard shell that could not be penetrated by the sperm, or where the young are born alive. In all vertebrates which have hard eggshe-

(sharks, rays, reptiles, birds, and monotremes), fertilization occurs before the shell is formed. In insects, on the other hand, fertilization takes place after the formation of the shell, the sperm penetrating through a small pore.

In animals with internal fertilization, the sperms may be conveyed either in a seminal fluid secreted by special glands or in spermatophores with a protective envelope that is dissolved or broken open in the female genital tract. Fluid semen occurs in dipterous flies, spiders, birds, and mammals, while spermatophores are found in grasshoppers, scorpions, octopuses, and salamanders —to pick a few examples at random. In insects, the sperm may be stored in the female for relatively long periods, up to several or many years in the case of the queen bee.

In most animals with internal fertilization the male possesses a penis, which is thrust into the female vagina in copulation, depositing the sperm therein. In many insects, the penis is concealed within the terminal abdominal segments and is only protruded or everted at copulation. There may be a variety of accessory male structures such as hooks and processes of different kinds that serve to clasp the female genitalia and interlock with them in complex ways. In mammals, the penis is flaccid except when the individual is sexually excited, a condition that leads to the erection of the penis, which becomes enlarged and stiffened as the spongy corpora cavernosa are distended by blood under pressure. A penis "bone," or baculum, is also present in many species of mammals. In some animals there are two penises: in sharks they are usually called "claspers"; in lizards and snakes, they are known as hemipenes. (*See* Reproduction: *Physiology of Reproduction.*)

There are several groups of animals in which the sperms are not transferred directly from the genital aperture of the male to the female, but undergo a double transfer. Three instances may be cited. (1) In the dragonflies the male genital aperture is on the ninth abdominal segment, but there is a pouch on the ventral side of the second and third abdominal segments to which the male transfers the sperm for storage. When copulation takes place the sperms are conveyed from this pouch to the female genital aperture. (2) In spiders the terminal segment of the male palps is enlarged and contains a seminal pouch. The male sheds a drop of semen from his genital aperture onto the web and then dips his palps into it, drawing up the sperm into the cavity in the palp; later, in copulation, the palps are used as "sperm guns" to inject the semen into the female aperture. (3) A somewhat similar arrangement exists in the cephalopods (squids and octopods), in which one of the arms of the male (the so-called hectocotylus) is specialized for conveying groups of very elaborate spermatophores to various parts of the female's body or into her mantle cavity. In *Argonauta* the male is minute by comparison with the female and lacks the characteristic shell; its largest organ is the hectocotylus arm which is detached in copulation and penetrates into the mantle cavity of the female, where it moves about autonomously for a while.

Dwarf males, parasitic on the females of their own species, occur in a number of groups of invertebrates. Certain peculiar mollusks (family Entochonchidae), which are endoparasitic in sea cucumbers, have much simplified wormlike bodies with a cavity containing the eggs and a number of minute males which consist of a testis with hardly any other tissues. Minute dwarf males also exist in the worm *Bonellia*, where they live in a special section of the uterus of the female. In this instance it is known that the free-swimming larvae that settle down on the sea bottom remote from a female themselves develop into females. If, on the contrary, they settle down on the proboscis of an adult female they develop into the minute parasitic males and migrate to the uterus later. A secretion from the female proboscis is apparently responsible for masculinizing the larvae.

Some unusual types of copulation occur in certain hermaphroditic invertebrates. In snails each individual discharges a large calcareous "love dart" into the flesh of the other, which stimulates the partners to complete the mating pattern. In most hermaphroditic mollusks each individual of a pair fertilizes the other, but in mollusks of the genus *Aplysia* copulatory chains are formed, each individual acting as a male to the one in front of it and as a female to the one behind. In the parasitic worm *Diplozoon paradoxum*, which occurs on minnows in Europe, two individuals become permanently fused together in sexual union.

(M. J. D. W.)

VI. SEX RATIO

The relative proportion of males and females at birth or at some other specified stage of the life cycle is usually expressed as number of males per hundred females. In man and the higher animals generally, sex is normally determined at fertilization by the chromosome constitution of egg and sperm (see *Sex Determination*, above); this leads to an expected sex ratio of equality at conception—the primary sex ratio. What is observed and recorded is usually the secondary sex ratio—the sex ratio at birth. The primary sex ratio is usually unknown, although in the case of the laboratory mouse and the fowl, when all eggs fertilized can be accounted for, the primary ratio has been found close to equality. The secondary sex ratio, however, frequently departs from equality, and sometimes the disparity is large. Interest in the sex ratio stems mostly from this difference. Search for the causes of disparity may elucidate problems connected with sex determination, differential mortality of the sexes before birth or maturity, and variations in sex ratio in different human populations. Ability to change the sex ratio experimentally may lead toward controlling it in favour of one sex or the other, an age-old ambition of animal breeders.

In lower forms of life, the sex ratio is greatly modified by environmental agents such as weather and population conditions. Several instances of such influence have already been described under *Sex Reversal and Intersexuality*. This section is primarily concerned with the sex ratio in man and certain other mammals.

1. Newborn.—In all races of mankind, more boys than girls are born. The ratio is generally considered to average about 106 males per 100 females (51.5% male), a figure that applies to whites of the United States. Among U.S. Negroes, the sex ratio is 102.6 to 100, with a slighter excess of males. This difference is not peculiar to the United States: W. Heape (1908) reported sex ratios in Cuba to be 108.4 for whites and 101.1 for Negroes, and S. de Jastrzebski (1919) found sex ratios in Cape Province to be 105.4 for whites, 102.6 for Negroes. At the upper end of the scale are Greece and Korea with sex ratios of 113.2 and 113.1 (W. T. Russell, 1936); Spain with a ratio of 111.1 (C. Gini, 1908); and the Jews of Austria with a ratio of 109.1 (De Jastrzebski, 1919). A more complete listing with references is provided by P. S. Lawrence (see *Bibliography*).

No one has given a completely satisfactory biological explanation for the excess of human males at birth. The disparity is particularly puzzling since a number of other species having the same type of sex-determining mechanism as man show an excess of females. The sex ratios reported from different countries are usually based on large numbers; thus differences are statistically significant.

2. Stillbirths.—If the mortality that occurs between conception and birth affects the two sexes differentially, then the secondary sex ratio would differ from the primary sex ratio. Such differential mortality is believed to occur, though the evidence is conflicting.

Figures based primarily on early U.S. census data showed an increasingly greater male mortality the younger the stillborn fetus and point to an even greater disparity in the proportion of the sexes at the time of fertilization than at the time of birth. The reliability of such data from registration reports has been challenged, however. For example, A. T. Hertig's examination of more than 1,000 spontaneous abortions submitted by physicians and hospitals in the Boston area suggests that about half the embryos cannot be classified for sex. Moreover, as many as half of all abortions are induced and rarely submitted for examination. The second difficulty is the one of determining the sex of young embryos, particularly from examination of the external genitalia. Mistakes can easily be made up to the fifth month, and even the opinion of experts is unreliable for embryos

younger than 11 weeks. Since most writers agree that the incidence of abortions is higher in the early months of pregnancy (at least one-half of all abortions occurring in the first three months), the sex ratio of "all abortions" remains unknown and hence the sex ratio at conception remains an open question. If more girls were lost than boys, then the primary sex ratio could be close to equality. With no differential mortality, or greater loss of boys, the primary sex ratio should be as high as or higher than the secondary sex ratio.

Museum specimens are in a special category, and the extensive collection of the Department of Embryology of the Carnegie Institution of Washington has been examined a number of times. C. Tietze (1948) made microscopic sections of the gonads (ovaries or testes) of 5,787 embryos ranging in prenatal age from three to seven months and found no significant variation in the proportion of males at any stage. The sex ratio of the whole sample is 107.9 males to 100 females (51.9% males). The discrepancy between these findings and census data (the latter admittedly less accurate for early months) is not easy to reconcile. It has been pointed out that the Carnegie collection is not a random sample of abortions and hence may not represent the general population. T. McKeown and C. R. Lowe (1951) made a study of the sex ratio of stillbirths related to cause of death and duration of gestation; they classified the 7,066 stillbirths from records in Birmingham, Eng., for the years 1936–49 as follows: (1) disease in, or accident to, the mother; (2) fetal malformation; (3) difficult labour; (4) ill-defined or unknown causes. The sex ratio of stillbirths (all causes) increases with the duration of pregnancy (from 99.2 at seven months to 133.1 at nine months and over), with the sex ratios of the four classes of stillbirth differing from one another.

McKeown and Lowe's data indicate that the relative proportions of the sexes change from month to month, and that after death male fetuses are retained in the uterus longer than females. It must be concluded that the actual primary sex ratio cannot be inferred from a combination of figures for secondary sex ratios and figures for abortions. Although the mechanism of sex determination indicates a 1 to 1 ratio at conception, the real ratio is unknown. In the absence of facts, the hypotheses that have been advanced concerning unequal production of X- and Y-bearing sperm, differences in sperm motility, or ability to penetrate the egg have not been confirmed.

3. Human Populations.—Every continent except Europe seemingly has an excess of males, but in every continent except Australia the numbers of the two sexes approach equality. Even countries like India, which have not been greatly affected by migration, show an excess of males.

The geographical distribution of the sexes is far from uniform and is subject to changes from both long range and short range forces. In the United States the influence of the frontier has been decreasing, whereas cities have proved a stronger attraction for females, who now make up more than half the urban population. The difference between city and country is characteristic of civilizations of Western Europe and its offshoots. It has been largely explained by demand for female labour in cities, especially for clerical positions and domestic service, and for male labour in the country. However, other influences cooperate with migration, since the female excess in urban populations generally applies to all ages. There is also evidence for a higher sex ratio at birth in urban than in rural areas in countries of Western Europe but not in the United States.

There is an excess of male deaths even in infancy, when social causes, like the greater exposure of males to accident, exert little effect. This must be biological in nature just as is the slight but uniform excess of males at birth. Also, except for limited periods related to reproduction, male mortality is higher at all ages.

4. Variations in Human Ratios.—When data do not fit a generally accepted hypothesis, the procedure is to look for special causes to explain the anomalous cases. For human beings, not subject to experimental control, frequently there is cause to question the data themselves. Then, again, there may be disturbing elements peculiar to human populations. One factor that could influence sex ratios in sibships is concerned with the effectiveness of a preference for one sex over the other, or a preference for a family containing both sexes. Presence of only one sex in a given family is not, of itself, an indication of anything unusual, for the presence by chance of a family of all boys, or all girls, has a probability of $(1/2)^n$ where n represents family size. Thus, out of 64 families of six, we expect, on the average, one family to contain only boys and one family to contain only girls. Results of statistical tests for family planning do indicate, however, that there is an effort to balance the sexes, but deviations from what would be expected if there were no planning are low. There seems to be no effective preference for boys.

Family planning, with preference for sibships containing both sexes, will not change the proportions of the sexes, but merely increase the proportion of families with longer than otherwise expected sequences of one sex. There is the added complication that large families that deviate from expectation because of real genetic influences on sex ratio cannot readily be separated from families that are large because of a continuing desire to have a child of the sex not yet represented. There is evidence that a sex preponderance in one generation may be followed by the same tendency in the next, and in some cases explanations invoking special chromosomal or cytoplasmic conditions have been put forward.

Numerous attempts have been made to correlate the secondary sex ratio with environmental influences such as season (low proportion of males in autumn and winter), birth order (usually more boys in first births compared to later ones), socioeconomic class (usually a higher sex ratio in upper levels), illegitimacy (fewer males in illegitimate births), effect of war (more boys born during or after wartime). The usual explanation for most of the above cases has been differential prenatal mortality, but the scientific validity of this is by no means established. Attempts to explain the significant increase in sex ratio toward the end of, or immediately after, World Wars I and II, in England, France, and Germany, on a basis of more first births, younger mothers, greater intervals between births, and other factors believed to reduce incidence of stillbirths, have not withstood close scrutiny by statisticians. The claim that the United States sex ratio was unaffected by World War II has been refuted by B. MacMahon and T. Pugh (1954), who found a significant rise in the secondary sex ratio for the years 1945 to 1947 inclusive, with a peak occurring in 1946. M. E. Bernstein (1958) advanced the hypothesis that in wartime, when opportunity for fertilization is decreased for a large segment of the population, proportionately more children will be born to the "more quickly fertile" parents, a group that has a relatively high incidence of male births at any time.

Interest in relations between disease incidence and the distribution of the ABO blood groups has been extended to the sex ratio with the first report, by L. D. Sanghvi, appearing in 1951. Real differences in sex ratio seem to occur in independent samples; these include high sex ratio (greater excess of males) among B offspring of B mothers and low sex ratio in A offspring of A mothers. Two explanations for the results have been advanced: one involves departures from randomness in egg and sperm unions; the other relies on known immunological phenomena concerning passage of antibodies through the placenta and postulates selective elimination of fetuses. However, studies on the relation between sex ratio of offspring and physique and temperament of parents have strengthened the conclusions from statistics that the father has an influence on sex ratio. This influence may be brought about through metabolic processes of some sort acting on the two kinds of sperms.

5. Experimental Alteration.—If natural selection adjusts the sex ratio to a certain optimum level for the species, then artificial selection should be effective in changing the ratio. A successful experiment using a mammal (rat), and applying selection directly to the sex ratio, is that of H. D. King (1918). She obtained, after six generations of selection, a line of rats with a high sex ratio (55% males) and a line with a low sex ratio (45% males). An attempt to duplicate the experiment using mice (D. S. Falconer, 1954) was not successful in changing sex ratio. J. A. Weir (1953, 1955, 1958) obtained high and low sex ratio lines

of mice by selection not for sex ratio but for high pH (low hydrogen ion concentration) of venous blood. Unlike King's rats, the strains are still existent. In reciprocal crosses between the high line (55% males) and the low line (45% males), the sex ratio of the progeny tended to follow the sex ratio of the male parent's line. The inbred lines have significantly different blood lactic acid levels and different activity levels. Artificial inseminations and double matings seem to rule out effects of seminal fluid, and no evidence could be found for differential mortality of embryos. The theory has been advanced that there is differential viability of sperm. H. G. Wolfe (1960) obtained an opposite response (high pH, excess females; low pH, excess males) when selection was for pH of arterial blood. Evidence for effects of differential mortality on sex ratio of mice has been found in certain strains.

For farm livestock, significant deviations may occur within the same species when different breeds, strains, or families are considered, and so pooled figures are not homogeneous. Jersey cattle averaged 52% males at birth, Guernseys 44%; most breeds of sheep show an excess of females. The dog resembles man in having a consistent excess of males, while the thoroughbred horse has exact equality of sexes. Sex ratio figures for wild species are frequently unreliable due to difficulties in sampling. Frequently hybrids show anomalous sex ratios; an excess of females is commonly encountered when the parents belong to different species.

There have been attempts to determine sex by methods designated to favour one kind of sperm over the other. Acid and alkaline douches have been tested on several different mammalian species. The results have been conflicting and negative for the most part. M. J. Gordon (1957) had some success in separating rabbit sperm into fractions by use of an electrophoretic technique. If a difference in the concentration of electrical charge between X-bearing and Y-bearing sperms exists, it should be possible to collect one kind of sperm at the anode, the other at the cathode. Gordon obtained 62 females and 25 males by artificial insemination from sperm collected at the anode and 29 females and 51 males from sperm that migrated to the cathode. This technique applied to cattle was not successful in deflecting the sex ratio from the theoretical value.

SEXTANT, one-sixth of a circle, 60°. The name is applied especially to an optical instrument for measuring angular distances, invented by John Hadley in 1731. Hadley's original instrument was, strictly, an octant, employing a graduated arc of one-eighth of a circle. The arc was later enlarged to one-sixth, to meet the needs of navigation. In current usage the term sextant often is applied to instruments with arcs of other than 60°.

The sextant is mainly used at sea, and the angle that is measured is the altitude of the sun (or a star) above the horizon (*see* Navigation). A familiar sight on an ocean steamer is the officer on the bridge "shooting the sun" at noon, in order to determine his latitude. The officer is looking through a small telescope straight at the sea horizon; but he sees also an image of the sun (dimmed by an interposed dark glass) which has been reflected into his field of view by an arrangement of mirrors described below. He moves an arm which turns one of the mirrors until the solar image appears just to touch the sea horizon.

The figure shows the construction of the sextant. ABC is a light framework of brass in the shape of a sector of 60°, the limb AB having a graduated arc of silver inlaid. It is held in the hand by a small handle at the back, either vertically in a position in front of the eye to measure the altitude of an object, or in the plane passing through two objects the angular distance of which is to be found. It may also be mounted on a stand. CD is a radius movable round C, where a small plane mirror of silvered plate glass (called the "index glass") is fixed perpendicular to the plane of the sextant and in the line CD. At D is a vernier read through a microscope, also a clamp and a tangent screw for giving the arm CD a slow motion. At E is another mirror (called "the horizon glass"), also perpendicular to the plane of the sextant and parallel to CB. F is a small telescope fixed across CB, and pointed to the mirror E. As only the lower half of E is silvered, the observer can see the horizon in the telescope through the unsilvered half, while the light from the sun or a star S may be reflected from the index glass C to the silvered half of E and thence through F to the observer's eye. If CD has been moved to make the image of a star or of the limb of the sun coincide with that of the horizon, it is seen that the angle SCH (the altitude of the star or solar limb) equals twice the angle BCD. The limb AB is graduated to avoid the necessity of doubling the measured angle, a space marked as a degree on AB being in reality only 30′.

SEXTANT

If the sextant is used on land, an "artificial horizon" is required instead of the sea horizon. This consists of a trough containing a shallow layer of mercury, which gives a truly horizontal reflecting surface. The telescope F is now pointed downward to view the sun's image reflected in the mercury trough; an image of the sun reflected by the sextant mirrors appears as before, and the two images are made to touch. The reading now gives the angle between the sun and its image in the mercury trough, which is double the angle between the sun and the horizon. In the air, however, the visible horizon is of no use, since its "dip" (below the truly horizontal direction) is large and unknown. The mercury trough is obviously unsuitable for use in an airplane. Hence some form of "bubble sextant" is used, in which a spirit level is reflected into the field of view in such a way that the centre of the bubble indicates the true horizon. Air sextants are often equipped with periscopes to eliminate the need for astrodomes.

SEXUAL BEHAVIOUR refers to all behaviour through which sperm is brought to the egg (*q.v.*). The mere existence of eggs, sperm and accessory reproductive organs does not ensure fertilization (*see* Reproduction). There must also be behavioural tendencies and reactions through which the male approaches and inseminates the female. This is accomplished in so many ways that it precludes a statement of the nature of sexual behaviour that will apply to all animals. However, the sexual behaviour of the different species has a common function: to secure the fertilization of the egg. The evolutionary influence of natural selection ensures that behavioural mechanisms are adapted to fulfill a function, but it does not limit the manner in which it is carried out. Also, the different parts of the overall sexual pattern in any one species are interrelated to make a coherent, integrated whole. Thus sexual behaviour, along with other aspects of animal biology, can be regarded as developing in the course of evolution and as being highly adapted to the environment, including other members of the species.

Although a good deal is known about the sexual behaviour of invertebrates, this discussion is limited to vertebrates.

VERTEBRATES (EXCLUDING MAN)

Establishment of Sexual Relations

Monogamy and Polygamy.—Among different species of animals reproductive relationships vary from casual and promiscuous mating to lifelong monogamous pairing. In general, the different classes of vertebrates (fishes, amphibians, reptiles, birds, mammals) are not characterized by particular types of sexual relationships. Widely differing patterns often can be found within the same class. In some fishes (*e.g.*, guppies and swordtails) mating is entirely promiscuous, and pairings endure briefly. Parental behaviour is absent and the young are in danger of being eaten by the parents. In other families of fishes, such as the cichlids, regular pairs are formed, nests may be established, and mates may co-operate in guarding the eggs or even in caring for the young. Some cichlids can distinguish their own mates from others of the same species and sex. In other species, such as the sticklebacks, a male may mate with several females, each of which lays her eggs in a nest he provides; he then immediately chases her away, to guard the eggs himself. Relatively little information is available about mating systems in amphibians and reptiles, but it appears that they are usually promiscuous, stable pairs occurring only rarely. Among many lizards one male may have several mates that stay near him for some time during the breeding season; but it is not clear if this relationship rests on mutual attraction or merely upon common reactions to the habitat.

In such birds as the European ruff and some species of grouse, the sexes may meet only for a brief period of courtship and promiscuous copulation, after which the females build nests, lay eggs and rear young alone. Many species of geese are strictly monogamous and the pair may endure over a number of migrations. Sexual relationships in these birds involve very strong bonds based upon highly developed individual recognition. Commonest in birds, however, are monogamous relationships for a single breeding season. This is observed in many species of songbirds, such as the American robin. There is little evidence that such pairs continue between breeding seasons; in the relatively few cases in which a pair becomes reestablished in successive seasons, it is not known if this is a function of individual recognition or a tendency of both birds to return to the same place.

Among mammals, too, various patterns may be found; most rodents appear to be casual and promiscuous; in wolves, monogamous families seem to prevail. In many mammals that live in herds (*e.g.*, antelope, deer, seals) males may have "harems"; it is not uncommon for one bull seal to have 40 or 50 cows.

Territory.—Sexual behaviour does not occur randomly in any location but is usually restricted to a specific site. Such an area is often defended by the male against competing males during the breeding season; the breeding area is usually weakly defended, if at all, at other times. Such a defended area is called a territory.

Birds.—The concept of territory was first elaborated for birds, and the classic and best-defined cases are described for avian species. Such songbirds as the snow bunting migrate in flocks, the males arriving at the breeding grounds days or weeks before the females. Shortly after the males arrive the flock gradually disintegrates as they take up residence in individual territories. A bunting on his territory perches on a prominent point such as a rock or bush, advertising his sovereignty with a characteristic song that warns other males away and attracts females. He vigorously guards against intrusion by other males and establishes boundaries by fighting with resident neighbours. While physical encounters may occur, stereotyped postures and vocalizations, which appear to have intimidating effects, play a dominant role. On his territory the male is almost always capable of dominating intruders; in boundary disputes each fighter becomes more effective as the battle moves closer to the centre of his territory.

Snow buntings and many other species of birds live during the breeding season entirely within their own boundaries. Many species of sea birds, however, breed in very crowded colonies on shore, leaving daily to feed from the ocean. The territory in such colonies may be as small as the area that can be defended by a bird sitting on its nest and stretching its neck; in other cases, the territory may be yards wide. Such territories do not protect the holders' food source, but they are defended as vigorously and elaborately as are the larger territories of land birds. In the sexually promiscuous European ruff, many males may gather in an area called a lek, and each defends a territory only a few feet wide. These territories serve solely for mating; nests are built elsewhere. (*See* also Bird.)

Fishes.—Although reproductive territories are not so widespread among lower vertebrates as among birds, many fishes and reptiles, and probably also amphibians, defend breeding areas. Many male salmon and trout defend well-defined areas of stream bottom, in which one or more females may spawn. The three-spined stickleback builds a nest, vigorously driving other males from the vicinity, and eventually leading a female to spawn there. Many other species of fishes defend territories during the breeding season, differing with respect to such factors as the sharpness of boundaries and the size of the area. The territory is not necessarily fixed, it may be the area around a movable object. Bitterling eggs live as parasites in the shell of a mussel, the male defending the surrounding area; his "territory" can be moved experimentally by moving the mussel. (*See* also Fish.)

Reptiles.—Such reptiles as small lizards of the genus *Anolis* show distinct territorial behaviour. Males of these species defend a definite area against other males during the breeding season; at other times of year they may attack other males that approach closely, but the aggressiveness is not limited to the territory, and the animals do not patrol boundaries as they do during the breeding season. (*See* also Reptiles.)

Mammals.—Information about the behaviour of mammals under natural conditions is meagre, but it is certain that many exhibit territorial behaviour. However, it is not always clear that defense is limited to the breeding season, as is characteristic of lower vertebrates. Some male mammals, including bears, hyenas and many wild relatives of the dog and cat, mark boundaries by depositing scent signals on rocks, tree trunks, hillocks and so on. These signals (or flags) may be either urine or the odorous secretions of special glands (located, in different mammals, on such parts as the head, lower abdomen and anus) to which other members of the species are highly sensitive. Among such polygamous herd-living animals as deer and antelope the territory may move with the harem, which may range considerably. (*See* also Mammal.)

Function of Territory.—The area defended during the breeding season does not serve exactly the same function in all species. It may be the complete living area; a mating area only; only the site of the nest; or it may be the vicinity of the female or an object required for egg laying. The common feature seems to be that the territory reserves for the defending animal something required for reproduction.

Mating and Copulation

The term mating is restricted here to behaviour immediately associated with the transfer of sperm to egg. Among vertebrates fertilization may take place inside or outside the body of the female. The term copulation is limited to animals in which fertilization is internal and in which mating requires insertion of the male copulatory organ into the body of the female. The term mating may be applied both to copulatory behaviour and to its functional equivalents in external fertilization.

Mammals.—Fertilization is internal in all mammals; copulatory movements are relatively stereotyped and fairly similar in most mammalian species. In four-footed mammals the female characteristically stands still, depressing the centre of her back, simultaneously elevating and exposing her genital region; the tail (if present) is usually raised or deflected to the side. This position, in which the depression of the back contributes to the rotation of the hindquarters, is called lordosis. The male mounts from behind, with forelimbs encircling or pressing the sides of the female's body. Camels, llamas and similar animals often copulate with the female sitting upright on the ground, legs folded beneath

while the male mounts from the rear. Among monkeys, the female bends sharply forward at the hips and the male mounts from the rear, holding himself erect by grasping her hips or waist.

Females of most mammalian species are relatively passive during copulation, although in a few cases the hindquarters may be moved from side to side or pushed against the male. The male makes pelvic thrusts that assist insertion and movement of the penis in the vagina, contributing to the stimulation of ejaculation. The behaviour of many male mammals during and after copulation suggests that something similar to an orgasm occurs. The male rabbit utters a sharp cry and falls off the female after delivering sperm. In male rats and guinea pigs there is a mild convulsive reaction during ejaculation, followed by a period of substantially lowered sexual responsiveness.

Birds.—In birds fertilization is always internal, but the males of most species lack an organ of copulation. Instead, both sexes have an external opening (the cloaca) under the base of the tail. The cloaca serves as the common outlet for the digestive and urogenital systems. During copulation the female stands still, typically tilted forward from the usual fairly upright position, with the back more or less level. The male hops or flutters to her back, maintaining balance by fluttering and flapping his wings. His tail is depressed while hers is raised, both simultaneously being rotated in opposite directions to bring the cloacas into contact. Transfer of sperm is very rapid and the cloacal contact usually lasts only a few seconds. In many species such postcopulatory displays as preening, ruffling of the feathers and pecking at the ground, suggest something analogous to orgasm. In such birds as ducks copulation usually is in the water, the female being somewhat submerged as the male swims from behind and clambers to her back.

Some groups of birds, such as ostriches and ducks, have a male organ of copulation partly everted from the cloaca, with similar functions to those of a mammalian penis. Copulation posture and behaviour in these species, however, is similar to that in birds that lack the organ.

Reptiles.—Most male reptiles have an organ of copulation (the hemipenis) normally located inside the body cavity and everted only during copulation. Snakes closely intertwine with sexual organs in contact; the male lizard usually straddles the lower body and grips the neck of the female in his jaws. Bending the hind part of his body to one side and downward, he gradually inverts his tail until their undersides meet, and the hemipenis is everted to enter the female cloaca. Copulation may last from several minutes to an hour or more.

Amphibians.—Among amphibians two basic types of mating behaviour are found: one in tailless amphibians (frogs and toads), the other in tailed amphibians (newts and salamanders). In frogs and toads fertilization is external. The male swims or climbs upon the back of the female and clasps her with his forelimbs at the level of her chest. She releases eggs in spurts, a few at a time, and the male delivers sperm in ejaculations synchronized with the release of eggs. The duration of clasp (amplexus) by the male may be greatly prolonged: in some cases, he may remain clasped for a full day before she begins to release eggs; in other cases she may begin to release eggs in a few minutes. He usually unclasps within a few minutes after the eggs are laid.

Tailed amphibians typically exhibit a curious form of internal fertilization. Following a more or less elaborate precopulatory courtship display, the male deposits on the ground a spermatophore, a small gelatinous stalk surmounted by a mass of sperm. The female, walking behind him during this ceremony, enfolds the cap of the spermatophore with the lips of her cloaca, thus taking it into her body where fertilization is accomplished. This type of fertilization takes place on land or in the water, depending on the species.

Fishes.—Among fishes fertilization may be internal or external, depending on the species. For example, the modified anal fin (gonopodium) of male live-bearing fishes serves as a guide for the sperm when it is inserted into the female genital opening. In most species, however, fertilization is external, the eggs and sperm both being released into the water. In the spawning of salmon, for instance, the female scoops out or cuts a shallow depression at the bottom of the home stream by quick, darting movements over the gravel, accompanied by sweeping movements of the anal fin. The male accompanies her and both may sweep over the nest, then circle back to repeat the process until there is a definite hollow in the gravel. Then both lie side by side over the nest and simultaneously extrude eggs and sperm. Although the two salmon may not come into actual contact, their spawning movements are synchronized, simultaneously becoming more vigorous and reaching a climax followed by reduction of activity and of apparent tension, reminiscent of orgasm in higher animals. Other fishes show a variety of methods for external fertilization. The male Siamese fighting fish blows bubbles to the surface where they adhere to form a so-called bubble nest. Following a series of preliminary activities, he swims over the female and bends himself into a rough U-shape, with head and tail down, enclosing her body. With the mates in this position, eggs and sperm are simultaneously released. The male swims down and retrieves a fertilized egg in his mouth, then swims upward and blows a bubble with the egg inside; the bubble rises to become part of the nest. The male three-spined stickleback leads the female into his tubular nest, swims through, then circles behind her while she is inside. He then moves forward and backward in quick jerks to tap her back with his snout. This stimulates her to deposit her eggs in the nest as she moves through; he follows and fertilizes them.

Nature and Function of Sexual Stimulation

The Nature of Sexual Stimulation.—Stimuli involved in courtship and sexual behaviour may be in any sensory modality; different species of animals differ widely in this respect. Mammals in zoos and in the wild clearly show that visual, auditory, olfactory and tactual stimuli may all arouse sexual excitement, and aid in the recognition of the mate. Olfactory stimuli are very important in most mammals; rats and dogs may respond to the odour of sexually receptive females while not being aroused by that of non-estrous females. In most mammals copulation is preceded by such activity as licking, sniffing and nibbling directed at the body of the mate, and particularly at the genital area. This behaviour undoubtedly represents for both sexes a combination of olfactory, tactual and other stimuli that is sexually arousing. Visual stimuli are also effective in mammals; the characteristic mode of locomotion of a female rat in heat may play a role in inducing the male to follow her, and female monkeys and chimpanzees often incite males to sexual activity by assuming postures characteristic of copulation.

Birds appear relatively insensitive to odours, and no reliable experimental evidence indicates that any of their sexual reactions are stimulated or guided by olfactory stimuli. However, both visual and auditory stimuli are important for birds. Females of many species appear attracted by male courtship songs and, in the case of the common parakeet, the female may be induced solely by the sounds made by other parakeets to lay eggs. Birds are highly visual in their behaviour generally; in a number of species the male can react differently and appropriately to stuffed and mounted specimens of either sex from its own species. The striking development of such features as special structures and patches of colour, which in many birds are displayed by courtship movements, is prima facie evidence of the importance of visual stimulation in their sexual life. Tactual stimuli also may be significant since some birds bill and preen each other before copulation.

Visual, auditory, tactual and chemical stimuli all operate among the lower vertebrates (fishes, amphibians, reptiles), several stimuli sometimes being effective at different stages in the sexual behaviour of the same species. For example, the males of some species of frogs approach and clasp on the basis of other frogs' visual characteristics, and then either maintain the clasp during emission of eggs and sperm or discontinue it immediately, depending upon whether the clasped animal emits the sound and has the body shape characteristic of another male or of an egg-laden female. Female salamanders are sometimes stimulated to follow the male during courtship by the secretion of glands on the surface of his body.

Many aspects of the courtship of fishes vary with visual stimulation. Experiments with artificial models, for example, show that a male three-spined stickleback on its territory acts differently depending upon whether the colour and shape of an approaching model are characteristic of a male or of a female.

Functions and Effects of Sexual Stimulation.—Animals of different species are subjected to a wide variety of stimuli from the mate and from the environment generally. This stimulation can induce a broad range of sexual effects, including not only immediate behavioural responses but also, more indirectly, pervasive physiological changes:

1. Most direct and obvious is the behavioural response immediately aroused or elicited by a specific stimulus. When another stickleback approaches a male on his territory he responds immediately. The response is likely to be an attack or an attempt to lead the caller to his nest, depending upon the visual characteristics of the visitor. The female stickleback, in turn, follows the male into the tubular nest. Male fence lizards adopt a characteristic posture when another lizard approaches; the approaching animal responds with a similar posture or by sexually receptive behaviour, depending on its sex. A territory-holding male bird similarly attacks or courts approaching birds, depending upon their visual characteristics and upon their immediate response to his singing. Sexually receptive female mammals of various species can be made to adopt copulation posture by touching or stroking them to imitate stimuli normally provided by the male just before copulation.

2. In addition, stimulation may sometimes contribute to the development of a mood, or temporary condition of sexual motivation. This is particularly important when mating requires close synchronization in the behaviour of the partners. In such cases, it is essential that both be aroused before mating occurs; many premating activities contribute to this. For example, the elaborate and protracted prespawning behaviour of the male and female salmon seems to culminate in the arousal of intense, synchronized spawning activity. In birds precopulatory displaying and posturing is widespread. In many species of pigeons and doves copulation is almost always preceded by billing, in which the mates peck and preen each other about the bill and head; often one bird will next place its bill in the mouth of the other, the heads of both move up and down in a pumping motion, and there may be an exchange of regurgitated food. Although billing sometimes occurs without being followed by copulation, copulation rarely occurs without this introduction. The nibbling, sniffing, licking and biting before copulation in most mammals appears to be needed to bring the mates simultaneously to the pitch of arousal required for effective copulation.

3. In many cases stimuli from features of the environment other than the partner appear essential for sexual behaviour. For example, experimental evidence indicates the nest of the male Siamese fighting fish to be essential in arousing sexually receptive behaviour in the female. Some species of toads that breed in the spring appear to depend on the appearance of ponds following heavy rainfall, without which they show no sexual behaviour. Species of weaver finches in Australia and in Africa breed only in the rainy season; in central Australia these birds live in large flocks, showing no sexual behaviour in dry weather. The sudden appearance of green vegetation, after rainfall occurring irregularly at any time of year, is followed by an outburst of courtship and breeding activity among the weaver finches in that neighbourhood; in dry areas some distance away birds of the same species may remain sexually inactive. It is commonly observed in zoos that the arousal of breeding behaviour very often requires not only the presence of a mate but such aspects of the normal breeding situation as cover, nesting material and appropriate places in which to nest.

In some animals the holding of territory is essential for sexual activity. When two pairs of the same bird species are kept in an aviary large enough for only one territory, only the pair that becomes dominant over the other is likely to develop breeding activity.

4. Finally, stimuli from the mate may induce changes in the activity of the endocrine glands (*q.v.*), sometimes with pervasive behavioural effects. A female pigeon may be induced to lay an egg merely by seeing a male court her through a glass plate. The production of an egg by the ovary occurs only in response to pituitary hormones, suggesting that the sight of the courting male stimulates the female to appropriate endocrine secretion. In other birds, such as sparrows, the presence of the courting male induces the female to secrete hormones that prompt her to build a nest.

The onset of puberty in female mice and the regular occurrence of estrous cycles thereafter are partially regulated by olfactory stimuli from male mice. The ovaries of minks produce growing egg cells earliest in the breeding season if other minks are visible.

The Role of Sex Hormones.—The gonads (testes and ovaries) secrete hormones that have important effects on mating behaviour. Among animals that breed at only one season of the year the gonads tend to regress to an inactive condition between breeding seasons. Increased activity of these glands during the breeding season is, in many animals, stimulated by environmental changes. For example, the springtime growth of gonads in birds is stimulated by the increased length of the day; when daylight is artificially prolonged males will develop large testes and sing vigorously in the fall, when wild birds of their species become sexually inactive. Such observations suggest that gonadal hormones may be influential in stimulating the sexual behaviour. Similar conclusions may be drawn from such mammals as the rat, in which the female undergoes a regular cycle of ovarian changes, culminating in the release of an egg (ovulation); in such species the female is sexually receptive only for the short time the egg is available to be fertilized.

Experimental removal of the testes in animals of many types is followed by loss or substantial reduction of sexual behaviour. Replacement of the missing hormones by injection acts in most animals to reinstate sexual behaviour. Removal of the ovaries in most mammals has an even more striking effect; sexually, the animal usually becomes completely unreceptive. Artificial replacement of ovarian hormones restores receptivity; in fact, such treatment may maintain continuous sexual receptivity over long periods even in such species as the rat, in which it normally occurs only for a very short period during each estrous cycle.

In such higher mammals as monkeys and apes sexual behaviour is not quite so closely tied to the sex hormones. Although apes have regular estrous (menstrual) cycles similar to those of lower mammals, receptivity is not so sharply restricted to the period near ovulation. In the case of male chimpanzees castration does not effect nearly so great a reduction in sex behaviour as it does in lower mammals.

The Role of Experience.—A persistent question concerns the contribution of individual experience, or learning, to animal behaviour. The answers vary from species to species and from one kind of behaviour to another.

In most lower mammals, as well as in birds and lower vertebrates, both sexes can be expected to show the normal pattern of sexual behaviour without previous sexual experience. However some aspects of experience before sexual maturity may contribute and, even though mating is adequately performed on the first possible occasion, in some species it tends to become more efficient with increasing experience. For example, the sexual behaviour of male guinea pigs reared in isolation from other guinea pigs is different from that of males reared in groups. When such animals are scored for quickness, vigour and efficiency of sexual approach the socially reared animals score persistently and significantly higher than those reared in isolation. In such species as the rat, males reared in isolation do not appear to differ in sexual behaviour from those reared socially. It is apparent that the role of early experience in the formation of such patterns varies from species to species.

In some fishes, males reared in isolation are slower and less efficient in mating approaches than are normally reared males. Pairs of inexperienced ring doves take longer to build a nest and lay eggs than do experienced pairs of the same age. It has been reported that a male ring dove reared in isolation from other birds preferred to mate with the hand of its keeper.

Learning that contributes to these patterns need not be specifically sexual, but may involve the establishment of general relations with other members of the species. For example, among the guinea pigs in which sexual behaviour is less effective in males reared in isolation, the difference from those reared in groups appears only if the animals are taken from their mothers at about 10 days of age. If they are kept with their mothers until the age of 25 days, and then reared as isolated or grouped animals, no difference appears in their later sexual behaviour. It appears that experiences during a very early period of life are crucially involved in this aspect of mating patterns.

Among primates the effect of learning is much more striking. Mature sexually inexperienced male monkeys sometimes have difficulty during initial contacts with receptive females. Adult chimpanzees without copulatory experience rarely succeed in achieving sexual union, no matter how co-operative the female may be. Erotic arousal is easily evoked in the naïve male ape, but he needs a great deal of experience and practice before this generalized excitement leads smoothly into a well-integrated and complete copulatory pattern. Female monkeys and chimpanzees, on the other hand, appear to show much more nearly adequate patterns of sexual behaviour at their initial experiences.

The effects of experience and of hormones may interact in some species. For example, if male guinea pigs (reared both in groups and in isolation) are castrated, the sexual behaviour of all drops to a very low level. If after about 10 weeks they are injected with male hormone, sexual activity rises, but only to the level characteristic of each group before castration. If male cats are castrated, the effect on sexual behaviour is in part a function of the animal's experience. Cats that have had no sexual experience before castration fail to show more than minimal attempts at copulation which, if they appear at all, die away rapidly. In those with sexual experience before castration, the ability to perform sexual activities may persist for some time and then die away very slowly. It appears that sexual activity in these cases is a joint function of hormonal and experiential influences.

Sexual Behaviour and Evolution

Evolution of Sexual Behaviour.—The elaborate organization of sexual behaviour is in part a consequence of evolutionary selection, having evolved in adaptation to the environment (which includes other members of the species). Thus each pattern depends partly upon the kinds of stimulation to which the given species is sensitive. In many animals one or the other sex may be highly sensitive to very specific kinds of stimuli; in such cases the sensory capacities of the mate provide a powerful selective influence upon the evolution of sexual behaviour and structures. For example, such structures as sexually erectile plumes and crests in some birds undoubtedly evolved because they accentuate and enhance sexual behaviour.

Sometimes the adaptive necessity for striking courtship behaviour may conflict with the equally pressing need for avoiding predators. Thus among some birds drab, inconspicuous males may have concealed patches of brilliant colours visible only when they spread their wings, erect crests, and so on.

Evolutionary relationships among species are sometimes shown very well by their sexual behaviour patterns. In some genera of doves, for example, the courtship movements may be very similar indeed, in spite of considerable interspecies variation in such characteristics as plumage colours and song. In this case the sexual pattern may be a more reliable guide to species relationships than other more traditional criteria. Students of evolution have used sexual behaviour patterns as criteria of interspecies relationships among such groups as fishes, lizards and ducks.

Role of Sexual Behaviour in Evolution.—Sexual behaviour also plays a role in the formation of species. For one species to evolve into two descendent species, it is usually held essential that it be divided into two populations isolated by a geographical barrier; it then is possible for them to evolve in different directions. If the populations are later merged by new migrations or by the disappearance of geographical barriers, the two incipient species may interbreed to reduce their genetic differences. In other cases, however, the disparate development of two species can continue, because both have evolved so differently that they will no longer interbreed. There may be differences in habitat preference that prevent members of the different groups from meeting; anatomical differences may make mating impossible; or differences in courtship behaviour may bar interspecies stimulation. There are many cases of closely related species living in the same area with little or no hybridization; differences in the pattern of sexual behaviour often play an essential role. Field observations and laboratory experiments often demonstrate that the failure of various species to interbreed arises from a lack of responsiveness of one species to stimulation offered by the other, or to a lack of correspondence in normally interlocking aspects of sexual behaviour. *See* Evolution, Organic. (D. S. Le.)

HUMAN SEXUAL BEHAVIOUR

Taboos in western culture and the immaturity of the social sciences have impeded research concerning human sexual behaviour. In the late 19th and early 20th centuries such European writers as Sigmund Freud, Havelock Ellis, Richard Krafft-Ebing (*qq.v.*), Albert Moll, Wilhelm Stekel and Magnus Hirschfeld were among the first to present studies of human sexual activity based on extensive case histories. By the 1920s they had laid the groundwork for more extensive statistical studies in the U.S. by R. L. Dickinson, K. B. Davis, L. M. Terman, G. B. Hamilton, C. Landis and A. C. Kinsey. Of the two major organizations for sexual study the Institut für Sexualwissenschaft in Berlin (established in 1897 by Hirschfeld) was destroyed by the Nazis in 1933. The Institute for Sex Research (begun in 1938 by Kinsey at Indiana University) continued in the 1960s with the study of many aspects of human sexual behaviour. Much of this discussion rests on the findings of the Institute for Sex Research (hereafter abbreviated I.S.R.). These data, largely based on interviews, were the most comprehensive available at that time for the U.S.; comparable bodies of data did not exist for other countries.

The I.S.R. data have been the subject of criticism that can be directed at all such interview research. It has been stated that the people interviewed may not have constituted a fully representative sample since some persons refused to be interviewed. It has also been observed that people do not always tell the truth, either with conscious intent or as the result of inaccurate remembering and sincerely held fantasies.

Being acutely aware of the problems of sampling, reliability and validity, the I.S.R. took some precautionary measures. Reliability was estimated by interviewing some respondents again after a lapse of at least two years. Statements were validated in many instances by separately interviewing sexual partners, chiefly husbands and wives. In a small number of cases reported data were corroborated by observation. In an attempt to overcome volunteer bias in sampling, defined groups were selected and worked with until 90% or more of their members had been interviewed. Nevertheless the sample does have deficiencies; the data, at least in some cases, should be regarded simply as approximations. Basically the conclusions deal with the approximate prevalence of specific forms of sexual behaviour; since moral or ethical evaluations are beyond the scope of the scientific method, none have been attempted.

Mammalian sexual patterns clearly demonstrate evolutionary origins for most of man's sexual behaviour. For example, masturbation, foreplay, homosexual behaviour and interspecies copulation are found, sometimes abundantly, in other mammals. However, the most prevalent sexual activity in all mammals is heterosexual.

All human societies face the problem of regulating sexual behaviour, since unrestrained sexuality would disrupt established social patterns. Yet severe restraints also can be disruptive since sexual expression contributes to the psychophysiological well-being of most people. Societies have sought solutions through widely varying systems of reward and punishment, encouraging behaviour held to be beneficial and discouraging activity considered detrimental. There are great differences among societies as to what is judged to be beneficial or detrimental. Among pre-

literate societies marriage is the primary social device for regulating sexual behaviour; many societies also encourage or tolerate premarital intercourse as a prelude to marriage. Adultery is more severely regulated, particularly for females; incest and forced sexual relations are condemned with few exceptions. (*See* MARRIAGE, PRIMITIVE.)

Sexual behaviour in the European-American culture (especially in the U.S.) has been much better documented statistically than in other cultures. Subcultures within a given country may show wide sexual variation; in the U.S. some of these differences as reported by I.S.R. can be summarized in the following way. The upper social level, chiefly people with higher education and occupations of marked social prestige, tended to show acceptance of and seemed most likely to engage in foreplay, heterosexual petting, masturbation, nudity, mouth-genital contact, and a variety of coital postures. The lower social level, typically those with a minimum of education and in occupations of lesser prestige, exhibited more acceptance of premarital coitus, prostitution (*q.v.*) and a wide variety of sexual partners.

While it has been widely held that the considerable differences in sexuality between males and females depend upon variation in gross anatomy and physiology, some authorities believe that other factors account for most of the divergence. One difference, the relative slowness of females to become aroused and to reach orgasm, has been discussed since the days of Ovid. Kinsey has suggested that coitus is a poor criterion by which to measure this difference; when speed of arousal and sexual climax in self-stimulation were considered, this difference was considerably narrowed. One of the most striking contrasts is the reported interest of males in a variety of sexual partners and of females in long-time association with one partner. I.S.R. data indicated that such differences derive from a male tendency to be more easily conditioned to respond sexually (especially to visual stimuli) and were interpreted as being both cultural and inherent.

One important measure of sexual activity is total sexual outlet, defined as the sum of orgasms derived from all sources including self-stimulation, dreaming or interaction with any other living being. While some individuals reported they derive their total outlet from only one source, most named two or three sources. A few interviewees of both sexes claimed the use of as many as six different sources in a relatively short period of time. Total reported sexual outlet for the sample of males studied by I.S.R. reached its maximum between ages 16 and 20, decreasing gradually but steadily thereafter. In this respect, total outlet followed the same course as most other physiological functions. The total outlet reported by unmarried males averaged about three orgasms per week between ages 16 and 20 and declined to slightly less than once per week by age 60; married men in the sample indicated a decrease from nearly five per week to about once per week. The opinion that males are sexually most active in their late 20s and early 30s was not verified. While the data indicated a peak of total outlet in the late teens, the peak of activity, in terms of rapid response and repeated climax, may be found even earlier in life.

Unmarried females showed a different aging picture; unlike the males, they did not seem to begin frequent sexual activity shortly after puberty. The total outlet of unmarried females studied rose progressively with age until the late 20s and then remained at essentially the same level (four to six orgasms per month) until the 50s. There appeared in most cases no cessation, or even diminution, of sexual activity or response as a direct result of menopause (*q.v.*). The gradual increase in the total outlet reported by these unmarried females is partly due to the fact that females apparently require some time in which to learn to achieve orgasm. Virtually all of the males said they had experienced orgasm within two years after puberty while only about a quarter of the females reported such experience. Only about three-quarters of the females who had never married by age 40 had ever had an orgasm from any source.

The total reported outlet of the married female showed the same aging picture found in males; this effect seems largely dependent on the aging processes of her spouse.

Nearly all preadolescents apparently have the ability to respond sexually, and many have the ability to achieve orgasm. Orgasm, apparently identical with that of adults, has been observed in infants of both sexes. I.S.R. data on preadolescent sexual activity and response supported the Freudian view of the early development and prevalence of preadolescent sexuality (*see* PSYCHOANALYSIS).

Premarital intercourse is acceptable behaviour in most societies of the world; in the U.S. it is legally punishable. About two-thirds of college-educated males interviewed by I.S.R. reported premarital coitus, in contrast to almost all of the lower-social-level males. Reported frequencies were much greater for the lesser-educated male, averaging once to twice a week in younger years, whereas for college-educated males they were only about once a month. Data on the number of men who go to prostitutes remained fairly constant throughout the 20th century, but the frequency of visits apparently decreased by half. About half of the females who married by 20 years of age reported premarital intercourse as opposed to two-thirds of the females who delayed marriage until after age 30.

Petting to orgasm as a premarital sexual activity appears to have been elaborated and extended in the upper social levels of the U.S. Roughly one-sixth of the lower-level males indicated this experience, in contrast to about half of the upper-level males, according to I.S.R. findings. The reported frequency of this behaviour reached its peak by age 25, when it averaged about once in three weeks. It never accounted for more than 3% of the total outlet of any segment of the male sample. The females studied reported petting to orgasm somewhat less commonly. However, petting represented a higher percentage of the total claimed premarital sexual outlet among the females: 5%–15% in various subsamples.

Marital intercourse accounted for most of the sexual behaviour reported by both sex groups. In the U.S. more than 90% of both sexes eventually marry; I.S.R. interviews indicated that marital coitus accounted for about 85% of the outlet in this group. In upper social levels among older people marital intercourse accounted for less than two-thirds of the outlet for both sexes; in lower levels about 90%. Frequencies stated for the early years of marriage, if the marriage occurred by age 25, averaged about four times per week, but by the 50s they averaged once per week or less. About half of the married males and one-quarter of the married females reported extramarital intercourse. For the lesser educated respondents this usually was placed in the early years of the marriage and for the better-educated interviewees in the later marital years.

Most preliterate societies seem unconcerned about masturbation (deliberate self-stimulation) but consider it a poor substitute for heterosexual activity. Studies in the U.S. find more than 90% of adult males say they have masturbated to ejaculation; this report was even more common among males of upper social levels. Among single males Kinsey found that masturbation apparently accounted for 50%–80% (varying with social level) of the total orgasms experienced during adolescence to age 15, but that this proportion dropped to 20%–45% for single males by age 30. Married males said that masturbation accounted for 2%–10% of their sexual outlet.

In contrast, reports by Davis, Dickinson and Beam, Landis and Kinsey showed that only 50%–60% of U.S. females interviewed say they have ever masturbated to orgasm, and the frequency is also considerably less than that volunteered by males. Differences in incidences of masturbation among females by social level were found by Kinsey, but these differences were less pronounced than among males. Masturbation apparently accounted for about 10% of the total outlet of married females at all ages. There is no evidence that masturbation is physiologically harmful; it may be helpful to females in avoiding frigidity in coitus.

Anthropology offers almost no information on orgasm during sleep for preliterate societies. In the U.S. studies almost all the upper-social-level males say they have experienced such nocturnal emissions as contrasted with only about three-fourths of the lower

level males. In I.S.R. interviews it accounted for about 15% of the outlet for upper-level unmarried males but only for about 5% for lower-level males. In marriage, however, such dreams constituted 2%–6% of the total outlet. Only about one-third of the females in the U.S. sample said they had experienced orgasm while asleep, with little difference among social levels. Such dreams accounted for only 2%–3% of the outlet of both the single and married females.

Orgasms during sleep seem to involve other factors besides the release of tensions resulting from lack of waking sexual outlet. Older males particularly have reported that a reduction or cessation of sexual outlet is not followed by a compensatory increase in nocturnal emissions. In some cases coital orgasm seems to induce or increase nocturnal emission. Discharges during sleep were rarely judged by males to be sufficiently frequent to meet their needs.

Surveys have shown that homosexual activity is more often allowed in preliterate societies than forbidden. G. P. Murdock reported that of 193 different societies, 28% accepted the practice among males and 11% accepted it in females. Only 15% rejected male homosexuality and 10% rejected female homosexuality. The remaining groups tolerated such behaviour under special circumstances or were doubtful in their attitudes. In the U.S., where such activity even between consenting adults with few exceptions is illegal, Kinsey found that nearly one-third of the males and one-fifth of the females claimed some postpubescent overt homosexual experience.

The vast majority of those reporting homosexual experience say they have also had heterosexual experience, usually within the same period of their lives. Only a small percentage of either sex appear exclusively homosexual. Reported frequencies of homosexual activity to orgasm in the I.S.R. sample averaged about once in three weeks for the single males of grade-school and high-school education in their late teens and early 20s and about once in ten weeks for the single, college-educated males at the same ages. The frequency decreased with age and was, of course, considerably less for the married males. Females said their frequencies of homosexual activity to orgasm were nearly as high as did the males with the same social-level differences. About 1%–2% of the married females admitted overt homosexual experience. I.S.R. findings failed to verify the concept that there is inevitably an overt, conscious homosexual phase or stage in early life. Nor was there evidence that such behaviour necessarily accompanied general symptoms of neuroticism, immaturity or emotional maladjustment. (*See* also HOMOSEXUALITY; LESBIANISM.)

Sexual contacts between humans and other animals seem relatively uncommon and ordinarily appear to occur in the first two decades of life. As many as 50% of young unmarried rural males, however, reported such contact (17% to orgasm) according to Kinsey (*see* also SEXUAL DEVIATIONS).

In summary, most postpubescent humans seem to require some sexual activity (including orgasm) for their psychophysiological well-being; but with great interindividual variation. Some apparently need only minimal activity, while others seem to require more than daily orgasm.

Physiological factors (*e.g.*, ill-health, age and hormonal changes) clearly play a role in human sexual behaviour. However, what are loosely called psychological and social elements seem to be of paramount importance. For example, degree of religious devoutness has definite correlates among sexual attitudes and behaviour, as do social customs. Within the past century Terman, Kinsey and others have reported pronounced changes in U.S. social customs; for example, such investigators judge that premarital intercourse has become more common, especially among females, and that the double standard which imposes more restrictions on women than men is being replaced not too slowly by a single standard.

Human sexuality is extremely complex and many of its aspects are poorly known. Much more scientific study will be needed before it can be said that adequate knowledge of the subject is available. (W. B. Po.; P. H. G.)

LEGAL ASPECTS

Human societies attempt to regulate individual sexual behaviour through education, religion, informal social pressure, medicine and, ultimately, law. Education, religion and informal social pressures formulate standards of action primarily by precept and persuasion, although elements of coercion may be present as in the threat of exclusion from religious communion, punishment in afterlife, disgrace and ostracism. The medical approach to sexual deviation may be psychotherapeutic or physical; *e.g.*, administration of hormones to homosexuals, emasculation of violently aggressive males. Some of these techniques, including possible confinement for indefinite periods in mental hospitals, undoubtedly exert an *in terrorem* effect which, however, is purely incidental to other objectives. Legal techniques for control of individual sexual behaviour are, by contrast, predominantly coercive. It is true that a convicted rapist or sodomist may receive psychiatric treatment in prison. A long sentence or delayed parole may be justified as necessary to prevent the dangerous convict from attacking others; *i.e.*, the purpose here is to incapacitate rather than to punish. But, by and large, penal provisions relating to sexual activity seem designed to deter people from violating prescribed standards, by exemplary punishment of those who break the rules. The drastic consequences of penal violation and the availability of less punitive methods of regulating sexual behaviour suggest that the criminal law should be reserved for the most serious departures from standards supported by virtually unanimous opinion in the community.

The principal laws designed to control sexual behaviour are those penalizing rape, sodomy, adultery and fornication, incest, prostitution, indecent assault, indecent exposure and obscenity (*see* RAPE; ADULTERY; INCEST). These offenses may be divided into two groups. One involves physical aggression against unwilling victims, as in forcible rape, violent homosexual attack or indecent assault. The other involves such acts as illicit intercourse or voluntary homosexual relations, acceptable to the immediate participants but offensive to relatives, neighbours or a substantial group in the community. It is with the latter group of offenses that this discussion is primarily concerned, since it presents distinctive problems in law enforcement. Voluntary participants in forbidden sexual behaviour do not usually complain to the authorities and, since the offenses are committed in private, only a small proportion of the activity comes to the attention of law-enforcement officials. Complaints by willing participants may be suspect as blackmail efforts. Attempts to enforce laws against homosexuality, fornication or prostitution may lead to such undesirable police practices as entrapment (luring the suspect into proposing or committing a violation) or unconstitutional intrusion upon premises. The most striking consequence of employing the penal law to suppress behaviour that is condemned primarily because it affronts nonparticipants is the great variety of laws and enforcement policies that necessarily ensue. Nations and states, and social and religious groups within each community, differ in the extent to which they are outraged by violations of sexual mores, in their estimates of the seriousness of the police problem and in their concern for individual freedom to deviate from ordinary norms. Thus, while laws against theft, assault and murder are universal and basically uncontroversial, sex laws vary enormously and are constantly in debate.

For example, fornication (heterosexual intercourse of unmarried persons) is not criminal in England and other countries outside the U.S. About a dozen states in the U.S. take the same position, but the majority penalize a single act of illicit intercourse or at least an "open and notorious" illicit relationship. If a married person is party to an illicit relationship, the offense becomes adultery which is quite generally punishable in the U.S., although not in England, Scandinavia, the Soviet Union or Japan, to name a few examples. In France and some other countries a distinction is drawn between adultery by a wife and adultery by a husband. The adulterous wife and her paramour are punishable generally, but adultery of the husband is punishable only in specified circumstances; *e.g.*, where the offense occurs in the marital abode, or in the case of a prolonged illicit relationship. The variety of atti-

tudes toward penal repression of illicit intercourse is further shown by the range of punishments that may be imposed in those states that do punish the activity: from petty fines up to five years imprisonment. The Louisiana Criminal Code of 1942 and the American Law institute's Model Penal Code exclude illicit intercourse from the category of criminal offenses.

Anglo-American codes provide penalties as severe as life imprisonment for homosexual intercourse, even if the relations are voluntary and between legally competent adults. So-called sodomy laws, actually proscribing a variety of sexual contacts, appear to apply even to married couples. No comparable regulations are found in the codes of Denmark, France, Italy, Mexico, Sweden or Switzerland, among others. The Wolfenden committee in England and the American Law institute in the U.S. have recommended abolition of criminal provisions in this area, except in cases involving violence, children or public solicitation to commercial vice.

Having sexual relations with a child generally is punishable as rape even if the child participates willingly. The critical age ranges from 7 to 18, with 16 the most common. Often the statutes recognize several age brackets and provide higher penalties (approaching or equaling those for violent rape) in the lower age brackets. Obviously a mature male who takes advantage of a child lacking comprehension of the physical and other consequences of intercourse is objectively dangerous as well as flouting strongly held views of propriety. However, the statutory rape laws appear to have gone well beyond the objective of dealing with such dangerous characters. Generally, it is no defense that the male himself was a child, perhaps younger than his "victim," or that he mistakenly but reasonably supposed that his partner was over the critical age, or even that the young female was a prostitute (a minority of states do make previous unchastity a defense). Such legislation penalizes (with severity appropriate only to rape) behaviour that is criminologically indistinguishable from illicit intercourse.

Prostitution is penalized throughout the U.S., although informal police toleration in certain districts is not uncommon. In England it is not criminal for a woman to sell her sexual favour, but she may not solicit business in public places to the annoyance of passersby.

Under the expanding influence of psychiatry, a number of U.S. state legislatures have enacted so-called sex-psychopath laws. The common feature of these laws is provision for commitment of sex offenders for therapy until they may be safely released. The concept of sex offense is variously defined, but generally extends to rape (including statutory rape), consensual homosexuality, indecent assault and indecent exposure. The commitment may be authorized before or after conviction, upon request of the prosecutor and certification by psychiatrists. These laws have been criticized on a number of grounds. The definition of sex offense is in most cases so broad as to include some activity not regarded as manifesting significant psychopathology. The indeterminate sentence is held warranted neither by the dangerousness of the offender (for example, exhibitionists or homosexuals typically do not progress to violent assault) nor by substantial prospect of cure. Not only are psychiatrists divided on diagnosis and treatment of these cases but often a legislature that is quite ready to authorize indefinite commitment fails to appropriate funds sufficient to provide adequate therapeutic effort. Thus in actual administration the sex-psychopath law may result in what amounts to a life sentence for what many consider a petty infraction of sexual conventions.

Obscenity laws may be considered as relating to sexual behaviour since obscenity is generally defined as material that appeals to or arouses prurient or morbid sexual interest. However, the chief impact of the laws is upon those who commercially disseminate alleged pornography; among these entrepreneurs it is money making, rather than sexual behaviour, that is being regulated. Nevertheless it is clear that the legislative purpose is to curtail the opportunities of ordinary people to look at erotic material. The idea is that such stimulation leads to overt illegal sexual behaviour. However, evidence linking exposure to obscenity with overt misbehaviour is far from conclusive, and some scholars believe that the voyeur (like the exhibitionist) is substituting a comparatively harmless outlet for sexual drives that might otherwise be expressed more aggressively. In any event, repression of obscenity raises formidable legal problems in view of constitutional guarantees of freedom of speech and other forms of intellectual and artistic expression. When legislatures use the concept of obscenity to prohibit dissemination of information and devices relating to contraception, as is often the case, the impact upon private sexual behaviour is obvious.

Legal aspects of sexual behaviour include not only the penal measures reviewed here but also much nonpenal legislation; *e.g.*, laws authorizing divorce for adultery or sodomy, or restricting the rights of illegitimate offspring.

SEXUAL DEVIATIONS are ways of sexual behaviour that replace normal copulation. This article will be confined to certain practices that either do not terminate in normal intercourse or involve some degree of physical injury. Normal sexual desire has (1) as its object a person of the opposite sex of more or less the same age as the person feeling the desire; and (2) as its mode of expression the love play and intercourse necessary for the fertilization of the female. In the sexual deviations, the object may be unbiological (for instance a person of the same sex, a child or an animal) or the mode of expression only may be at fault.

Deviant conduct occurs in animals as well as in human beings; it is apparent sometimes in the immature, but more often in animals deprived of a normal outlet for their instincts. Conditioning may have a great deal to do with causing it, although much arises spontaneously. In human beings it may be regarded as caused either by some biological residue (apes appear to pass through a stage of undefined sexual activity) or, according to Sigmund Freud, by a fixation of the individual libido resulting from a traumatic experience during an early stage of development. Environment, however, appears to be important as a possible cause.

Sexual deviations may lead to unhappiness in marriage, either because they often result in impotence or because of the very nature of the deviation. They are also a major factor in the demand for prostitution and may further lead to crime. Medically, however, they are regarded as psychosexual diseases, and the law is becoming more and more willing to allow deviant offenders to be treated rather than punished. (*See* also SEXUAL BEHAVIOUR: *Legal Aspects*.) Some deviations are definitely curable; some can be alleviated. Since glandular and other physical conditions play only a slight part in causation, treatment must be mainly by psychotherapy. This treatment may take either a short or a long

time, according to the nature of the cause. Patients should not be encouraged to marry until there is strong evidence of cure. Those who cannot be cured should avoid drinking alcohol, as it may release deviant behaviour and lead to criminal charges. Treatment by conditioning has been tried but has not proved satisfactory. In this therapy the patient is shown objects associated with his perversion and is given an emetic such as apomorphine at the same time. More useful is the administration of estrogens, which suppress the libido in males, simultaneously causing atrophy of the genitalia. This treatment should be used in patients unsuitable for psychotherapy or in whom it has failed.

Homosexuality.—Homosexuality (*q.v.*), the female form of which is known as lesbianism (*q.v.*), is the most important sexual deviation. In it the object of desire is unbiological, so that the mode of expression is perforce at fault.

Sodomy.—This expression may be understood in a number of senses: (1) as denoting any homosexual practices between men, in allusion to the story of Sodom, in Gen. xviii–xix; (2) as denoting anal intercourse; (3) as synonymous with bestiality (*see* below); and (4) as comprehending a number of activities ranging from hand-genital contacts with minors to mouth-genital contacts between persons of the opposite sex. In this article it is understood in the second sense.

Anal intercourse has been observed in apes and is often accepted as normal between men and boys in preliterate societies, notably during initiation rites. In civilized communities it occurs between male homosexuals (though far less frequently than is commonly supposed) and also between men and women. Between men the passive partner as well as the active one may experience pleasure, but if the act is committed by force the passive partner may suffer painful injuries. The man who plays the active role with one partner may assume the passive with another.

The desire for anal intercourse has been explained (1) as arising from lack of opportunity for vaginal intercourse, an explanation that cannot be maintained in view of men's committing it on women; (2) as caused by Pavlovian conditioning, which may be of some importance in the case of boys habituated to the passive role; (3) as caused by fixation of the libido at the stage where sexual interest, after being centred on the mouth, is centred on the anus, from which it would normally, but for the fixation, proceed to the genitalia; and (4) as a dominance phenomenon, a view that receives some support from the behaviour of apes (*e.g.*, when a weaker one turns to be mounted sexually if a stronger one threatens to steal its food) but does not account for human behaviour in all its aspects.

Bestiality.—Intercourse between human beings and animals (Lat. *bestiae*) is tolerated and even approved by some primitive peoples, but many societies condemn it and some even punish it with death. In some parts of the United States it was estimated by A. C. Kinsey that between 40% and 50% of boys brought up on farms have some sexual relation with an animal, vaginal intercourse being commoner than anal. The cause of the desire for it is not known for certain; sometimes, however, there may be some inhibition against relations with another human being, or the animal may symbolize a loved human in the deviant's subconscious mind.

Sadism.—Named after Count D. A. F. Sade (*q.v.;* called the marquis de Sade), sadism is the obtaining of sexual pleasure from acts of cruelty. Sometimes sadism and masochism (*see* below) are regarded as correlative aspects of a single deviant tendency, sadomasochism. Sadism appears to shade off into nonsexual cruelty and may be classified in degrees as (1) cruel or destructive acts performed with pleasure but not appreciated as sexual in nature, including certain sports, arson and lynching; (2) cruel acts without erection or ejaculation but with some sexual satisfaction; and (3) acts of outrage accompanied by full sexual satisfaction and associated with erection and ejaculation, including necrophilia (intercourse with the dead) and rape.

Sadism is the association of aggressive behaviour with sexual arousal. Sigmund Freud suggested that this was caused by fixation of the libido at an early stage when aggression was manifested by biting, scratching, soiling or some such act. L. Bender and F. J. Curran suggested that rivalry was important, deprivation of love and parental aggression being other factors. The sadist uses hate as the emotional currency where the normal man uses love. He injures the parts of the woman a normal man wishes to caress. There is often an obsessional element present, and B. Karpman (*The Sexual Offender and His Offenses*, 1954) states, "The abnormal expression of sadism represents inner tension and anxiety for which the act is attempted relief. He relieves fear by doing to another what he fears might be done to him."

Sadism is most dangerous when the sadist is also a psychopath and therefore has no inhibitions against antisocial conduct. Murders and violent assaults are then done repeatedly until the sadist is caught. Characteristic of the sadistic murder are (1) periodicity; (2) cutting, stabbing and sometimes biting, sucking the blood and even eating the flesh; (3) concomitant sexual excitement; (4) the occasional revisiting of the scene of the crime; and (5) normal behaviour until the next occasion. The mental abnormality of most sadists does not amount to insanity and is no excuse for their crimes, but when sadism shades off into schizophrenia the individual may be regarded as irresponsible.

Masochism.—Masochism, the converse of sadism in the sadomasochistic deviation, is named after an Austrian novelist, Leopold von Sacher-Masoch (1835–95), whose writings are centred on it. It is the seeking of what would normally be painful to oneself to induce sexual pleasure. Often associated with fetishisms, it may take the form of a desire to be dominated, humiliated, degraded, enslaved, bound and even castrated and may also appear unrelated to sexual pleasure, as in the practice of religious flagellation.

Masochism appears to be the impulse to hurt others reversed onto oneself. Freud suggested that it was a manifestation of being beaten in infancy. He also believed that the girl's discovery that she had no penis was a strong factor in feminine masochism. K. Horney suggests conditioning as the cause.

Masochism is less important socially than is sadism. It does not inspire murders or assaults, but sometimes the masochist is injured so severely as to need medical care or even to die. Thus anyone co-operating with a masochist may lay himself open to charges of assault, manslaughter or murder.

Voyeurism.—Voyeurism, or scopophilia, is the reverse of exhibitionism (*see* below), just as masochism is the reverse of sadism. Thus it is often called scopophilio-exhibitionism. It is the obtaining of pleasure by watching other people undress or by watching sexual intercourse. Voyeurs who are not satisfied by vaudeville acts such as strip tease may go to immense trouble to spy on other people and have been known to fall from buildings and trains in doing so.

Voyeurism appears to be derived from the infantile desire to look. Young monkeys, for instance, are absorbed by the sight of their mother's genitals, and children are intensely curious about sexual matters. Psychoanalysts believe that the voyeur has repressed experiences of the primal scene (*i.e.*, observation of parental intercourse) and is trying to overcome a fear of castration. In normal men the wish to look is a sign of sexual attraction and preliminary to further advances, but in voyeurism all the sexual pleasure comes from looking at nakedness or intercourse. Probably those who watch mating couples show considerable empathy, or imaginative involvement in the act. A. C. Kinsey and his associates pointed out that voyeurism and exhibitionism form an important part of preadolescent sex play. This suggests that, like most deviations, it stems from immaturity.

Voyeurs are called "Peeping Toms," from the legend of Godiva (*q.v.*) and are prosecuted for behaviour contrary to common law and, in England, to the Justices of the Peace act of 1361.

Exhibitionism.—Exhibitionism, or sexual exposure, is exposing the genitalia to obtain sexual pleasure. It usually occurs in males. In exhibitionism the mere showing of the genitals is not sufficient: some emotional reaction (disgust, horror) is sought from the person to whom exposure is made. Ejaculation may occur at or after exposure, or the patient may masturbate.

Some psychoanalysts think that exhibitionism is the denial of castration and that the shocked reaction of the onlooker proves to the exhibitionist that his own unconscious fears are unfounded.

This explanation is not altogether satisfactory. Psychoanalysts also believe that the castration shock is greater in women than in men, and if this is so one would expect women to be more sexually exhibitionistic than men. Men with castration fears are not necessarily exhibitionistic.

Biologically, exhibitionism is the seeking of love. It can be seen in the love dances of many animals, including apes, and in the sexual dances of primitive tribes. Clinically it is often seen, as N. K. Rickles suggested, in men who live in a female-dominated environment. Where a man is subservient to an assertive wife or mother he sometimes goes to some place where he exhibits himself as a means of proving his virility. This desire to assert his masculinity may be uncontrollable.

SEYCHELLES, a group of islands in the Indian Ocean about 600 mi. NE of Madagascar, which with the Amirante Isles, Cosmoledo Group, and other islands far to the southwest form the British colony of Seychelles. The nearly 90 islands in the colony have a total area of about 145 sq.mi. (375 sq.km.). The capital is Victoria on Mahé Island.

Physical Geography.—The Seychelles Group rise from a submarine ridge where depths are less than 50 fathoms. The largest are high granitic islands, others being low coral islets little above sea level. Innumerable coral heads rise almost to the surface. The high islands are of hornblende granite, gray and red, with dikes of younger igneous rocks, but there are no signs of recent volcanic activity; large boulders litter the lower slopes. All are much weathered and covered with laterite, in places yards thick. The islands and the Seychelles ridge are thought to be remnants of ancient Gondwanaland (*q.v.*).

The largest of the Seychelles is Mahé Island, 16 mi. (26 km.) long and 4 mi. (6 km.) wide, with an area of 56 sq.mi. (145 sq.km.). Its backbone is formed by a continuous rugged ridge with many spurs, in parts bare and precipitous with striking vertical grooves, and there is a bold westward projection, also mountainous. Many heights exceed 2,000 ft., the greatest being Morne Seychellois (2,971 ft. [906 m.]). The land rises steeply from the coast, but there are small areas of lowland at the mouths of many turbulent rivers, which have cut deep ravines. The east coast has an almost continuous coral reef, adjoining it in the south and a mile out in the northeast with an intervening lagoon.

A few miles east of Mahé there are small, hilly islands and rocky islets, the largest being Saint Anne Island, reaching 830 ft. (253 m.), and Cerf Island. Praslin Island, 26 mi. NE of Mahé, is 8 mi. long and rises to 1,260 ft., near it to the east being Curieuse, La Digue, and Félicité islands, all high. Silhouette Island, rising to 2,467 ft. and very prominent, though only 8 sq.mi. in area, lies 10 mi. NW of Mahé. The low Bird and Denis islands, on the northern edge of the coral bank, overlook the ocean, which deepens abruptly to more than 2,000 fathoms. The bank is similarly steep elsewhere, and anchorage is possible at only a few places on its outer edge.

Climate.—The Seychelles have a hot, humid, equatorial climate, with a small temperature range. The period November–April, with two-thirds of the annual rainfall, is very sultry, almost saturated air being brought by light winds between west and north. May–October is drier with constant, stronger winds from between east and south. At Port Victoria mean monthly maximum and minimum temperatures are 27° and 25.5° C (81° and 78° F). Rainfall, very variable, averages 92 in. (2,337 mm.) annually and ranges from 107 in. (2,718 mm.) in the west of Mahé to 55 in. (1,397 mm.) on Denis Island. There are no tropical cyclones, and gales are few.

Vegetation.—Most of the original rain forest of the high islands has been destroyed for timber or to provide land for crops. On Mahé little remains except in the secluded highlands, where locally useful trees include capucin (*Northea sechellarum*), ironwood (*Stadtmannia sideroxylon*), bois rouge (*Neowormia ferruginea*), and bois montagne (*Campnosperma seychellarum*). Many palms have survived, and on the low islands they are prominent from the sea. Many species of screw pine (*Pandanus*) are common, and mangroves are abundant along the coasts. Among the ferns is the beautiful tree fern. Introductions include the coconut palm (ubiquitous up to 1,000 ft. and economically important), breadfruit and jack, litchi, mango, mangosteen, eucalyptus, casuarina, banyan, dragon's blood (a large *Dracaena*), cinnamon, vanilla, pineapple, and bamboo. A notable feature is the number of endemic plants, for old forms survive from the former continent and new ones have had time to evolve. They account for two-fifths of the species and include one family (Medusagynaceae, very local) and about a dozen genera. Among the six native palms is the coco de mer or double coconut.

Animal Life.—Partly as a result of man's interference there is a poverty of animal life. Of mammals only rats and some African and Indian species of bats remain; the dugong no longer frequents the island waters. Reptiles comprise two snakes and seven lizards (three endemic), of which one is a gecko varying in colour between the islands; turtles come ashore to lay their eggs, but the crocodile, once common, has been exterminated. Giant tortoises are found on Mahé. Of amphibians there are two genera of tree frogs. Birds of 15 species (13 endemic) include 3 pigeons, a black parrot, and a weaverbird, all closely allied to species in Madagascar, and an Indian myna. (W. G. KE.)

Population.—Uninhabited when first visited by Europeans, the Seychelles were colonized by Frenchmen from Mauritius, who brought their African slaves. In the 19th century they were joined by deportees from France and a few British and by African slaves freed from Arab dhows by the British Navy. Asians from China, India, and Malaya came in smaller numbers later, mostly as traders and shopkeepers, and miscegenation left few families of pure European descent. The census of 1960 revealed a total population of 41,041 (1964 est. 46,472). About one-third of the islands are inhabited, but four-fifths of the population lives on Mahé. Victoria, the only sizable town, has more than 10,000 inhabitants. In the mid-1960s the crude birth rate averaged 40 per thousand and the death rate 10.

English is the official language and the medium of instruction in schools, although French is allowed in the courts and legislative council. The commonly spoken language is a creole patois, a mixture of clipped French, much of it archaic, with words from African dialects and a few mutilated English words. Most of the population is Roman Catholic. Less than one-tenth is Anglican, and there are a few Seventh-Day Adventists, Hindus, Muslims, Buddhists, Parsees, and pagans. Witchcraft and voodoo also have their devotees. Street processions on saints' days with pilgrimages to a mountain church and picnics are very popular. There is little native culture, but tortoiseshell ornaments, lace work, raffia, and coco-de-mer mats and fans are sold to tourists.

History.—The Seychelles are believed to have been visited in the 12th century by ships from the Arabian Sea and Persian Gulf. They were known to Portuguese navigators early in the 16th century (Vasco da Gama, 1502; Pedro Mascarenhas, 1505) and were marked on Portuguese charts of 1502. The first recorded visit by a British ship was in 1609. The islands were explored by the Frenchman Lazare Picault in 1742 and 1744 and were formally annexed to France. Mahé, the largest island, was named after the then administrator of Île-de-France (Mauritius), Count Mahé de la Bourdonnais, and the group as a whole were called Îles de la Bourdonnais. In 1756 they were renamed Îles des Séchelles after the Vicomte Moreau de Séchelles, Louis XV's controller general of finance, and a *pierre de possession* ("stone of possession") was planted on Mahé.

The permanent settlement of the islands, which dates from 1768, was largely the work of Pierre Poivre, intendant at Mauritius from 1763 to 1772, who had the idea of establishing spice plantations in the Seychelles. However, when war broke out between Great Britain and France in 1778, orders were issued to the administrator at Mahé to destroy the plantations rather than allow them to fall

into British hands. As a result most of the spice trees were burned when in 1780 a French ship which put into Mahé for water and food, fearing to find the British in possession, hoisted British colours. The islands were surrendered to a British naval force in 1794, but they were to seesaw between French and British possession another six times before the final surrender to Britain in 1810. The Seychelles were formally ceded to Great Britain by the Treaty of Paris in 1814.

The Seychelles were at first administered from Mauritius through civil agents and, later, civil commissioners. The first of these was the Frenchman J. B. Quéau de Quincy, who when he died in 1827 had governed the islands continuously for 34 years, serving both the French and the British. In 1888 an order in council nominated an administrator and executive and legislative councils for the Seychelles, and in 1897 the administrator was given all the powers of a governor. On Aug. 31, 1903, by letters patent, the Seychelles were finally separated from Mauritius and became a crown colony. The elective principle was introduced into the legislative council in 1948. Since then two local government districts, Port Victoria on Mahé and Praslin Island, have been established based on adult suffrage and not on the educational, income, and property qualifications required in the case of the electorate for the legislative council. The legislative council was reconstituted in 1960 (see *Administration and Social Conditions*, below).

From time to time the islands have been used by the British government as a place of detention, the most notable instance in later years being the deportation there of Archbishop Makarios of Cyprus from September 1956 to March 1957.

Gen. C. G. Gordon, who was sent out to make a military survey of Mahé in 1881, propounded the theory that the Vallée des Cocos de Mer on Praslin Island was the site of the Garden of Eden. The coco de mer (*q.v.*), which Gordon considered the forbidden fruit, was known from seaborne specimens before the Seychelles were discovered and has (largely because of the impudicity of the shape of the nut) a remarkable historical reputation as an aphrodisiac.

Administration and Social Conditions.—The colony is administered by a governor with an executive council of four *ex officio* members and others appointed by the governor of whom one must be unofficial. The legislative council, for which elections were first held in 1948, has four *ex officio*, five elected, and three nominated (one unofficial) members. There are two elected district councils, on Mahé and Praslin islands, and nominated local boards for north and south Mahé and La Digue.

Justice.—This is administered through a chief justice presiding over the supreme court with civil and criminal jurisdiction and through two magistrates with restricted criminal jurisdiction. Peace officers on outlying islands can deal with minor offences. Civil appeals go to the Supreme Court of Mauritius and criminal appeals to the Seychelles Court of Appeal.

Living Conditions and Welfare.—Many houses are built of coral hewn into square building blocks. A 50% subsidy is provided for houses built by property owners for their employees. In the mid-1960s the minimum wage for agricultural workers was: (1) 43 rupees a month together with housing for a 30-hour week; or (2) 67 rupees a month with housing for a 45-hour week. There are a few registered trade unions. Personal income tax ranged from 5% on the first 1,000 rupees to 65% on any excess over 100,000 rupees. Those in distress can obtain public assistance. Nearly one-third of the children are illegitimate, and many are cared for by the government-aided L'Oeuvre de Sainte-Elisabeth under the Roman Catholic mission. There are five hospitals, a tuberculosis sanatorium, and several clinics (on Mahé, Praslin, Curieuse, and La Digue). The most prevalent diseases are amoebic dysentery, hookworm, tuberculosis, and gonorrhea.

Education.—In the early 1960s there were more than 30 primary schools, mostly government-run, 8 secondary schools, a technical and a vocational school, and a teacher-training college. Some Seychellois receive further education or vocational training in the U.K. In 1965 a new educational system was established giving greater opportunities for secondary education.

The Economy.—The economy of the islands is mainly agricultural and depends largely on the price of copra. The colony is not self-supporting. A development plan for the period 1964–66 envisaged expenditure of more than £765,000 on natural resources, public works, and communications, and on social services.

Production.—Besides coconut plantations of about 23,000 ac. (9,300 ha.), which are very important, cinnamon trees, patchouli, and vanilla are also cultivated for the export trade. Crops for local consumption include breadfruit, bananas, cassava, and sweet potatoes. Small numbers of pigs, cattle, goats, and poultry are raised for local needs. The government reafforestation plan had achieved 4,000 ac. of managed forests by the early 1960s. Fossil guano is worked on the outlying islands. Fish caught include bonito, mackerel, tunny, and shark; and large numbers of terns' eggs are collected, mostly from Desnoeufs Island in the Amirantes. There is little local manufacturing apart from a sisal rope factory, a coir factory, and some essential oil distilling plants.

Trade and Finance.—In the mid-1960s exports to Britain and other Commonwealth countries, chiefly copra (mostly to India), cinnamon bark and leaf oil, patchouli, vanilla, and salted fish, were valued at about 8,500,000 rupees annually. Imports, which exceeded 14,500,000 rupees in value, included flour, maize (corn), rice, sugar, kerosene and petrol (gasoline), and cotton piece goods. The currency is the Seychelles rupee, valued at 1*s.* 6*d.* and divided into 100 cents. Barclay's Bank Limited has a branch at Victoria, and there is a government savings bank. Revenue is derived largely from customs duties, income tax, and licences.

Communications.—There are about 90 mi. (145 km.) of motorable roads, one going almost all around Mahé. There are regular shipping services to Bombay (India), Durban (South Africa), Dar es Salaam (Tanzania), and Mombasa (Kenya); and a twice-weekly government launch service runs between Mahé, Praslin, and La Digue. Occasional passenger-cargo boats run directly from London and Singapore. There are no railways or air services.

The Seychelles Broadcasting Station transmits nightly from Mahé for several hours. (S. S.-Cl.)

SEYDLITZ, FRIEDRICH WILHELM, Freiherr von (1721–1773), Prussian Army officer who is unrivaled in history as a trainer and leader of cavalry, was born at Kalkar, near Cleves, on Feb. 3, 1721. His father, a cavalry major, died in 1728, and he was brought up by his mother in impoverished circumstances. At the age of 13 he became a page at the court of the Hohenzollern margrave Frederick William of Schwedt. There he was introduced to horsemanship and soon attracted attention by his daring equestrian feats. In 1740 he was commissioned in the margrave's regiment of Prussian cuirassiers. His first experience of fighting, in the War of the Austrian Succession, was unfortunate, as he was taken prisoner by the Austrians in Silesia (May 1742). In accordance with the custom of the times, however, he was quickly exchanged. By 1753 his enterprise and efficiency had come to the notice of the Prussian king Frederick II (the Great), who placed him in command of the 8th Cuirassiers, which soon became a model for the Prussian Army.

The Seven Years' War (*q.v.*) gave Seydlitz his real chance. After distinguishing himself at Prague (May 1757) and at Kolin (June 18), he was made a major general. At the Battle of Rossbach (Nov. 5, 1757) he commanded the whole of the Prussian Cavalry (38 squadrons) and won the battle almost unaided by the infantry, but a wound received in the battle kept him out of action for some time. His cavalry saved the day at Zorndorf (Aug. 25, 1758); and later, with a cavalry force of 108 squadrons, he covered the Prussian retreat at Hochkirch. He was wounded again on Aug. 12, 1759, in the disaster at Kunersdorf (Kunowice). At Freiberg (Oct. 29, 1762) he commanded a mixed force (infantry and cavalry) for the first time, and his fine leadership decided the battle.

After the Peace of Hubertusburg (1763), Seydlitz was made in-

spector general of the Silesian Cavalry and in 1767 was promoted to the rank of general of cavalry. Toward the end of his life he fell out of favour with Frederick the Great, but the two men appear to have been reconciled just before Seydlitz' death, which took place at Ohlau (Olawa) on Nov. 8, 1773. He was a man of fiery temper, quite incapable of remaining out of the thick of any fight within reach, but he had no opportunities as a strategist or in the higher military art. (C. N. B.)

SEYHAN, the name of an *il* (province) and a river in southern Anatolia, Turkey. The *il* (area 6,660 sq.mi. [17,249 sq.km.]; pop. [1960] 760,803) extends from the Mediterranean coast in the south to the inner slopes of the Taurus Mountains in the north. The northern part, which occupies two-thirds of the total area, is rugged and sparsely populated; agriculture and animal husbandry are the main occupations. The large plains of Adana and Ceyhan in the south are well irrigated and densely populated; the chief crops are cotton, cereal, sesame, flax, rice, and citrus fruits. Adana (*q.v.*) is the capital. The province is well served by rail and road.

Seyhan River (length 348 mi. [560 km.]) rises in the east of the middle Taurus Mountains and flows south-southwest through Adana (forming a delta above it) into the Mediterranean Sea. A dam with a power station, north of Adana, provides irrigation and electricity. (N. Tu.; S. Er.; E. Tu.)

SEYMOUR, HORATIO (1810–1886), governor of the state of New York and Democratic candidate for president in 1868. Born in Onondaga County, N.Y., on May 31, 1810, he attended Geneva Academy (the present Hobart College) and a military school in Middletown, Conn. He was admitted to the bar in 1832; served as military secretary to Gov. W. L. Marcy, 1833–39; was a member of the New York Assembly, 1842–46; and was elected mayor of Utica in 1842. The Democrats of New York nominated Seymour for governor of the state in 1850 but he failed to win election; two years later he succeeded in winning election but lost his bid for a second term in 1854, mainly because of his opposition to a bill prohibiting the sale of intoxicating liquor.

In national politics Seymour, a conservative, supported the policies of Pierce and Buchanan. While strongly supporting the preservation of the Union, he advocated compromise to avoid secession and war. When war came he gave his full support to the Union cause but opposed Lincoln's policies on emancipation, conscription, and military arrests. As governor of New York from 1863 to 1865 he felt that the draft quotas discriminated against New York City and appealed to President Lincoln to correct the situation. When the draft riots occurred in July 1863 he proclaimed the city and county of New York to be in a state of insurrection but in one of his speeches he adopted a conciliatory tone that weakened him politically. After the war, he was nominated as the Democratic candidate for president to run against Gen. Ulysses S. Grant. Though the popular vote was fairly close, in the electoral college Grant won 214 votes to Seymour's 80. In the years that followed Seymour took an active part in politics as a private citizen. He died in Utica on Feb. 12, 1886.

SEYMOUR, JANE: *see* Jane (Jane Seymour).

SEYMOUR OF SUDELEY, THOMAS SEYMOUR, Baron (*c.* 1508–1549), lord high admiral of England from 1547 to 1549, whose political intrigues led to his execution for treason, was the fourth son of Sir John Seymour of Wolf Hall, Wiltshire. His father held office in the royal household; his sister Jane became the third wife of Henry VIII; and on the accession of their son, the young Edward VI (1547), Seymour's elder brother Edward, duke of Somerset, became regent as lord protector. These connections, together with his own reckless and flamboyant character, determined Seymour's fate. From 1536, when he became Henry VIII's brother-in-law, he obtained minor employment at court and on diplomatic missions abroad, but he found the times more propitious after the renewal of war with Scotland in 1542. In 1544 he was appointed master of the ordnance and commanded the Channel fleet in the war with France; when his brother succeeded to the control of the state on the accession of Edward VI (January 1547), Thomas, created Baron Seymour of Sudeley (February), was also made lord high admiral, and at once began to intrigue for power.

His appearance and charm in 1547 won him the hand of Henry VIII's widow, Catherine Parr, and nearly proved dangerous to the adolescent Princess Elizabeth (later Elizabeth I), a guest in the Seymour household, to whom he openly made advances. It also impressed the boy-king Edward over whom the admiral exercised considerable influence. On the other hand, he used his office to enter into profitable, if criminal, relations with the Channel pirates, and by his arrogance and irresponsibility lost his brother's support. When, after his wife's death in September 1548, Seymour made plain his intention to marry Elizabeth, the protector had to act. In January 1549 Seymour was arrested for treason and felony; his guilt was manifest, and he was executed on Tower Hill, London, on March 20, 1549. The protector's Roman sternness toward his own brother was one of the charges raised against Somerset by the politicians who overthrew him later that year. (G. R. E.)

SFAX (Safaqis), second largest town and port of Tunisia, headquarters of Sfax governorate, lies on the Khalif Qabis (Gulf of Gabès) opposite the Juzur Qarqannah (Kerkena Islands) 82 mi. (132 km.) S of Susah (Sousse) by road. Pop. (1956 census) 65,635, including 3,168 Jews and 9,760 Europeans, many of whom left in the late 1950s. The old Arab town (medina), with its 10th-century great mosque and kasbah or citadel, is surrounded by the 9th-century tower-flanked walls pierced by three gates. The modern (former European) quarter, on a geometrical plan, stretches to the port and is flanked by suburbs on the north and southwest. Sfax is the market for the phosphates of the Qafsah (Gafsa; *q.v.*) region with which it is connected by rail. The production of olive oil is the chief industry; the fisheries are also important. There is some light industry, including metal factories and mechanical engineering. The town is the centre of a network of roads linking it with the rest of Tunisia. It is connected by rail north with Susah and Tunis, south with Gabès (Qabis), and southwest with Qafsah and Tawzar (Tozeur). The spring tidal range in Sfax port is 5½ ft. (1.6 m.), which is rare in the Mediterranean. The harbour, to which a channel 1¼ mi. (2 km.) long and of varying width gives access, was built in 1895–97 and has since been deepened. The phosphates enterprise of Gafsa has built huge stores there, and the greater part of the port's exports is phosphates. Other exports include oils, esparto grass, sponges, and dates; the imports are textiles, cereals, sugar, petroleum products, timber and other building materials, and machinery parts. The harbour was an important Axis base from November 1942 and was almost entirely destroyed by Allied air raids. It was captured in 1943 by the British army.

Sfax, built on the site of two small towns of antiquity, Taparura and Thaenae, was of little importance until the 11th century. It remained isolated and was inhabited by nomads. The Sicilians under Roger the Norman took it in the 12th century. In the 17th century it began to be surrounded by gardens and in the early 19th century by olive groves. The town was bombarded by the French in 1881 prior to their occupation of Tunisia.

Sfax Governorate (Safaqis *wilayat*) had a population (1956) of 338,268, including about 100,000 Muslims in the neighbourhood of the town. Area 3,425 sq.mi. (8,871 sq.km.). The governorate includes the wide coastal belt of sparse gardens and olive groves, extends westward over the steppes, and stretches southwestward to the phosphate-bearing Gafsa region. Its administrative area includes the Juzur Qarqannah. (J.-J. Ds.)

SFORZA, the name of a famous Italian dynasty, important for its role in Milan (*q.v.*), especially when that duchy was a field for the international contest between France and the Holy Roman emperors of the House of Habsburg. It was descended from the Attendoli of Cotignola (Romagna), a wealthy and warlike family.

Muzio Attendolo (1369–1424), nicknamed "Sforza" for his strength, became a distinguished mercenary captain in the wars of Italy. Like other *condottieri*, he served many masters and aspired to the possession of a patrimony if not a principality. He was most prominent in the wars of the Neapolitan succession at the time of Joan II (*q.v.*), in which finally he lost his life.

Muzio was certainly successful in acquiring lands and titles in Romagna and in Naples, but it was reserved to two of his sons

FRANCESCO (1401–66) and ALESSANDRO (1409–73), likewise *condottieri*, to achieve the status of princes. In 1445 Alessandro acquired possession of Pesaro, in the Papal States, where he was subsequently made vicar by the pope; his descendants retained the city, except during its conquest by Cesare Borgia (*q.v.*), until 1512, when Pope Julius II expelled them. Francesco had to wait longer and strive harder before winning himself a state. His first attempt, directed likewise against the Papal States, where for 14 years (1433–47) he held the March of Ancona, ended in failure and dispossession; and success, when it came, lay in the north of Italy in the duchy of Milan, which had long been one of the greatest Italian states. After his father's death, Francesco had entered the service of the last Visconti duke of Milan, Filippo Maria, a morose and unpredictable prince. For more than 20 years Francesco fought sometimes for Filippo Maria, sometimes against him. During the periods of uneasy harmony Francesco had succeeded in getting himself betrothed (1433) and then married (1441) to Filippo Maria's illegitimate daughter, Bianca Maria, receiving as dowry Pontremoli and Cremona; and he had attained also some promise of succession in the duchy itself. But Filippo Maria did not nominate Francesco as his successor when he died (1447), and it was primarily by right of conquest that Francesco triumphantly entered Milan in March 1450, overthrowing the unstable republic that had been proclaimed at Filippo Maria's death. For 16 years Francesco ruled as duke in Milan, though without formal recognition from his suzerain, the Holy Roman emperor Frederick III, whose price (in money) for a "legitimate" title was too high. His government, which in the March of Ancona had been burdensome because of the expense of perpetual war, seems in Milan to have been enlightened, though despotic. He himself was frugal, retaining the manners of a soldier, but his court conformed to the lavish fashion of the time and his children were raised under leading men of letters in humanist education.

Francesco left several sons, among them ASCANIO (1455–1505), who became a cardinal in 1484, worldly, magnificent, and lettered, and Galeazzo Maria and Ludovico il Moro, who in turn both ruled the duchy.

GALEAZZO MARIA (1444–76), whose wife, Bona of Savoy, was a younger sister of the French king Louis XI's consort Charlotte, and who desired the emperor to raise his duchy to a kingdom, was in many ways a capable ruler (for example, he introduced the cultivation of rice into the territory); he was also an active patron of letters and the arts. But the character traditionally given him is very different from his father's, showing him vain, extravagant, dissolute, and often cruel. He was murdered on Dec. 26, 1476, by three citizens of Milan, who hoped thereby to free their city from despotism; but no popular rising followed to endorse their deed, and the duke was rather mourned in his dominions, which in the past had several times stirred against his harsh taxation. Even so the murder did prepare the way for the end of Sforza rule by raising the problems and divisions of a regency.

Galeazzo Maria's son GIAN GALEAZZO (1469–94) never proved himself strong in mind or body, and after a period of conspiracy and violence, effective power passed (1479–80) to his uncle, LUDOVICO IL MORO (1451–1508), whose main concern thereafter was to retain control of the duchy. Ludovico, who in 1491 married Beatrice d'Este, a brilliant personality and no less ambitious than himself, is both celebrated and ill-famed in Italian history: celebrated for his court and for his patronage of such men as Leonardo da Vinci; ill-famed, though perhaps unjustly, for having encouraged Charles VIII (*q.v.*) of France to invade Italy and so begin a series of devastating wars. This was the effect of his design to rule perpetually in Milan and to displace Gian Galeazzo for good. In 1489 Gian Galeazzo had married Isabella of Aragon, granddaughter of Ferdinand I of Naples, and it was to conquer Naples from Ferdinand's heirs that Charles VIII entered Italy in 1494, with Ludovico's reluctant connivance. In September 1494 Ludovico was secretly invested with the duchy of Milan by the emperor Maximilian I, to whom he married his niece Bianca; and in October, after the timely death of Gian Galeazzo, he was chosen duke by the Milanese. His triumph, however, lasted only until 1499, when he was driven from power by Louis XII (*q.v.*) of France. Reinstated for a short time by the Swiss, he was eventually delivered by them to the French (April 1500) and died a prisoner in the castle of Loches.

The two sons of Ludovico, MASSIMILIANO (1493–1530) and FRANCESCO MARIA (1495–1535), took refuge in Germany. The former was restored to Milan by the Swiss in 1512 but, after the defeat of his allies at Marignano (1515), surrendered his rights to the victor, Francis I of France. He died later in Paris. Francesco Maria was put in possession of Milan after the defeat of the French at Bicocca in 1522. His death (Oct. 24, 1535) marked the extinction of the ducal male line of the Sforza.

The dukes Sforza-Cesarini (Rome) are descended from Bosio (1411–76), a bastard son of Muzio Attendolo. The counts Sforza, one of whom was the anti-Fascist statesman Carlo Sforza (1873–1952), descend from Sforza Secondo, one of Francesco's younger sons. Gian Galeazzo's daughter Bona married Sigismund I (*q.v.*) of Poland.

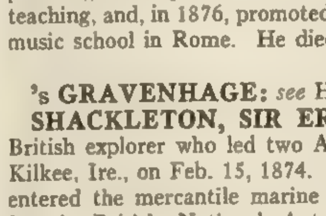
SGAMBATI, GIOVANNI (1841–1914), Italian pianist, conductor, and composer who promoted a revival in Italy of instrumental and symphonic music during the second half of the 19th century, was born in Rome on May 28, 1841. He studied the piano and harmony at Trevi. Later he returned to Rome where he took piano lessons from Liszt and gave recitals of works by German composers who had hitherto been neglected in Italy. In 1866 he formed an orchestra in Rome and conducted the first performances in Italy of Beethoven's *Eroica Symphony* and Liszt's *Dante Symphony*. He also introduced Beethoven's *Emperor Concerto*, playing the solo part himself. In 1867 he helped to establish the Società Romana del Quartetto. In 1869 he visited Germany with Liszt and became acquainted with the music of Wagner. His own compositions had attracted attention, and Wagner, while in Rome in 1876, secured the publication of two piano quintets by Sgambati and some of his songs. Besides chamber music, piano pieces, and songs, Sgambati composed a Requiem Mass, two symphonies, and a piano concerto. He devoted his later years to teaching, and, in 1876, promoted the foundation of the first public music school in Rome. He died in Rome on Dec. 14, 1914. (DY. H.)

's GRAVENHAGE: *see* HAGUE, THE.

SHACKLETON, SIR ERNEST HENRY (1874–1922), British explorer who led two Antarctic expeditions, was born in Kilkee, Ire., on Feb. 15, 1874. Educated at Dulwich College, he entered the mercantile marine service. He joined Capt. R. F. Scott's British National Antarctic ("Discovery") Expedition (1901–04) as third lieutenant and took part, with Scott and Edward Wilson, in the sledge journey over the Ross Ice Shelf when latitude 82° 16′ 33″ S was reached. His health suffered and he was invalided out on the supply ship "Morning" in March 1903. In January 1908 he returned to Antarctica as leader of the British Antarctic ("Nimrod") Expedition (1907–09). The expedition, prevented by ice from reaching the intended base site in Edward VII Peninsula, wintered on Ross Island, McMurdo Sound. A sledging party, led by Shackleton, reached within 97 mi. of the South Pole, and another, under T. W. Edgeworth David, reached the area of the South Magnetic Pole. Victoria Land Plateau was claimed for the British crown. On his return Shackleton was knighted and was made a companion of the Royal Victorian Order. In March 1914 the British Imperial Trans-Antarctic Expedition (1914–16) left England under his leadership. He planned to



THE BETTMANN ARCHIVE

SIR ERNEST HENRY SHACKLETON, PHOTOGRAPHED ABOUT 1905

cross Antarctica from a base on the Weddell Sea to McMurdo Sound, via the South Pole, but the expedition ship "Endurance" was beset off Caird coast and drifted for 10 months before being crushed in the pack ice. The expedition then drifted on ice floes for another five months and finally escaped in boats to Elephant Island in the South Shetland Islands. Shackleton and five others sailed 800 mi. to South Georgia in a whale boat, and then made the first crossing of the island, to seek aid. He led four relief expeditions before succeeding in rescuing his men from Elephant Island. A supporting party, the Ross Sea party led by A. E. Mackintosh, sailed in "Aurora" and laid depots as far as latitude 83° 30′ S for the use of the Trans-Antarctic party; three of this party died on the return journey.

Shackleton died on Jan. 5, 1922, at Grytviken, South Georgia, at the outset of the Shackleton-Rowett Antarctic Expedition in "Quest"; his exertions in raising funds to finance his expeditions, and the immense strain of the expeditions themselves wore out his strength. He was ambitious both for himself and for the honour of his country, but his outstanding characteristic was leadership. Courage, optimism, and endurance, coloured by a streak of romanticism, earned him the trust and devotion of all his men under the most difficult circumstances.

Shackleton's publications are *The Heart of the Antarctic* (1909) and *South* (1919).

See H. R. Mill, *The Life of Sir Ernest Shackleton* (1923); Margery and James Fisher, *Shackleton* (1957). (L. M. Fs.)

SHAD, fishes of the herring family (Clupeidae) that seasonally leave the sea and swim upriver to spawn. They are characterized by a notch in front of the upper jaw into which the tip of the lower jaw fits. They constitute the genus *Alosa*. Young shad have small teeth, but the adults are toothless. The American shad (*Alosa sapidissima*) ranges from Florida to Newfoundland, and, as a result of an introduction in 1871, from San Diego to British Columbia. It is marine, migrating along the coast to richer feeding grounds during the summer, generally northward and sometimes seaward 100 miles or more. In late autumn they evidently retire into deep water. The sexually mature shad reappear to enter rivers as early as January in the south or as late as June in the northern part of their range. They journey upstream as far as 300 miles or more, produce 30,000 to 156,000 eggs, and then return to the sea. The eggs hatch in 6 to 15 days, depending on temperature; the young remain in the stream until fall and then move downstream to the sea. Shad mature in their third or fourth year, and continue to spawn annually thereafter for several years. They feed on plankton, and attain a maximum length of about 2½ ft. They are excellent game fish, taking an artificial fly or live minnow when running upstream to spawn. They are a favourite food fish, over 10,000,000 lb. a year being caught by United States fishermen.

The Allis shad (*A. alosa*), of the coasts of Europe, has very numerous, long, and slender gill rakers; it attains a length of 30 in. and a weight of 8 lb. The twaite shad (*A. finta*) is smaller and has fewer and shorter gill rakers; the Mediterranean form (*A. f. nilotica*) is distinct from that of the Atlantic, and the species also includes some well-marked forms permanently resident in freshwater, one from Killarney and two from lakes in northern Italy.

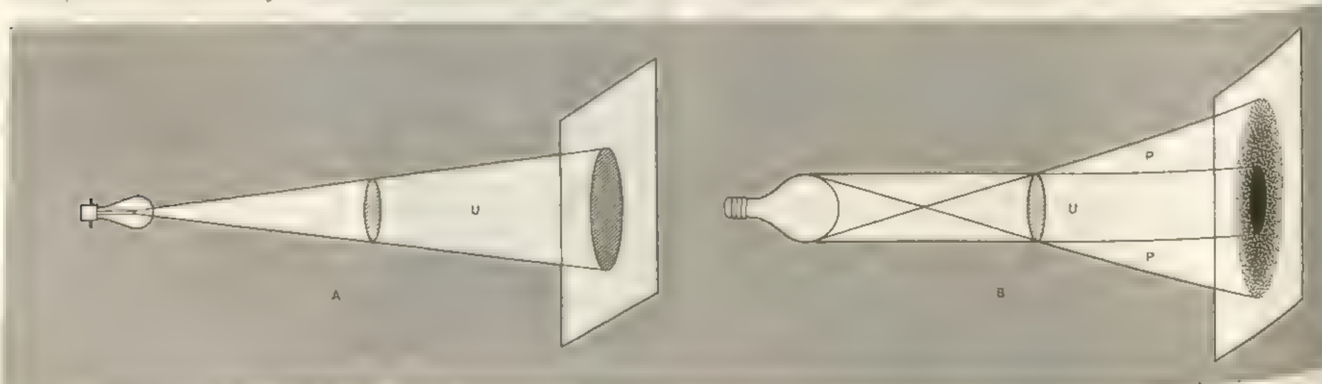
The shad of Black and Caspian seas (*Caspialosa*) have teeth on the roof of the mouth much like the herring. Another important related genus of fishes having a similar life cycle is *Hilsa*, with six species, ranging from east Africa to China. Gizzard shad, which resemble deep-bodied herring, form another family, the Dorosomidae. (L. A. Wd.)

SHADDOCK (Pummelo), a citrus tree, 20 to 40 ft. in height allied to the orange and the lemon, presumably native to the Malay and Polynesian islands. It is *Citrus grandis*, considered the parent type from which the grapefruit (*q.v.*) probably originated. The name "shaddock" is asserted to be that of a captain who introduced the tree to the West Indies. The leaves are like those of the orange, but have broadly winged petioles and are downy on the undersurface, as are also the young shoots. The flowers are large and white, and are succeeded by very large spheroid or almost pear-shaped fruits, resembling grapefruit, lemon yellow in colour, and with a pungent, tart but agreeable flavour. The pulp segments are either pallid or red, and shell out easily. The fruit is highly prized in the Orient. (L. D. B.)

SHADOW usually means that region of an illuminated surface from which the oncoming light rays are shielded by an opaque object. More generally, it can refer to any local changes in the intensity of radiated energy produced by placing some form of matter in its path.

If a source of light is small, as, for example, the filament of an automobile headlight lamp illustrated in part (A) of the figure, the light effectively emanates from a point and the shadow has a relatively sharp boundary between light and darkness. Its shape evidently will be that of the object producing it. If, on the other hand, the source has an appreciable size, as in part (B) of the figure, there is a region U of the total darkness called the umbra and also another P called the penumbra, in which there is a gradual transition from dark to light in going from the inner boundary to the outer. Viewed from the region of the penumbra, only part of the source may be seen, the rest being covered by the obstacle.

Pronounced shadows are not formed if there is more than one light source, except when one of these is much brighter than any other, as in sunlight. Shadows cast by the sun are not sharply bounded because there is always a perceptible penumbra. This is relatively unimportant for shadows cast at small distances; it is possible to read a sundial (*q.v.*) with fair accuracy. The umbra and penumbra assume vast proportions, however, for the shadows of the moon and of the earth. During an eclipse (*q.v.*) of the sun, the moon's shadow falls on the earth, and the penumbra covers the wide area where the eclipse is partial. An eclipse of the moon, on the other hand, occurs when the moon moves into the earth's shadow. The shadow of the moon on its own surface may make a good part of its sphere invisible, so that it appears from earth as a crescent. Another type of shadow occurs when sunlight penetrates to the ground through very small spaces between the leaves of a tree, or to the wall of a room through a hole in a window shade. Small circular or elliptical patches of light are seen which are actual images of the sun's disk, the spaces between the leaves serving to focus the light. The faithfulness of this image becomes apparent during a partial eclipse of the sun



SHADOWS CAST BY AN OPAQUE DISK USING (A) A SMALL LIGHT SOURCE, AND (B) AN EXTENDED SOURCE SUCH AS A FROSTED LIGHT BULB

when the patches of light become crescent shaped (*see* also CAMERA LUCIDA AND CAMERA OBSCURA).

The nature of a shadow may be modified when the light is deflected from its straight-line path by refraction (*q.v.*). Thus when the moon lies in the umbra of the earth's shadow during a total lunar eclipse, it is still visible by a faint copper-coloured light. This is light that has been bent inward by refraction as it traverses the mantle of air surrounding the earth. The light has a hue similar to that of a sunset because in both cases the light scatters substantially as it traverses a great thickness of air (*see* SKY). Refraction by the atmosphere also has the effect of delaying the time of sunset, that is, the time when the shadowing effect of the horizon is complete. As a result of the downward deflection of its rays, the sun appears to be higher than it actually is by an amount almost equal to its own diameter. Thus, if it were not for refraction, the sun would completely disappear at about the time when it is first seen to touch the horizon.

Shadows can form even without a screening object. A transparent substance may, by reflection or refraction, concentrate light in some places and deflect it away from others. The commonest example occurs when sunlight is reflected on a ceiling by a liquid with a disturbed surface. The shifting patterns of light and shade are produced by surface irregularities acting like curved mirrors to focus the light to a greater or lesser degree. Similar effects produced by refraction may be seen on the bottom of a clear pond when the sun shines through the waves. The air itself, when it has turbulent regions and irregularities of temperature, can act in the same way. Here the deflections of the light are so slight that the effects are only apparent when the source is a bright one of very small dimensions. For example, at the instant before a solar eclipse becomes total, darker areas called shadow bands are observed rushing across the landscape, an effect attributed to refractive effects of the upper atmosphere. On a laboratory scale, the same principle has been put to practical use in studying the flow of air around objects in wind tunnels by the Schlieren method (*see* AERODYNAMICS).

X-ray photographs are shadowgrams produced by absorption of the rays coming from the X-ray tube (*see* X RAYS). Sound vibrations, especially those of high pitch, may be screened off almost completely by large obstacles (*see* NOISE AND ITS CONTROL). Even when the source has small dimensions, the resultant acoustical shadows do not have sharp boundaries. The reason lies in an effect called diffraction, exhibited by all types of wave. It becomes more pronounced for longer waves, but occurs even for the waves of light, where the crest-to-crest distance is only about $\frac{1}{20,000}$ cm.

If the edge of an apparently sharp shadow is examined with a magnifier, the transition from dark to light is found not to be abrupt, several faint bands bordering the edge. These diffraction fringes are completely accounted for as a wave phenomenon, as are some other curious effects such as the existence of a minute bright spot at the centre of the shadow of a circular disk.

Spectacular diffraction fringes are observed when the edge of the moon passes in front of a star. The fringes sweep across the observing telescope at a rate corresponding to the frequency of audible sound waves, and may be recorded photoelectrically. From the clearness of these records, it is possible to deduce the diameter of the star's disk, provided it is greater than the apparent size of a one-cent piece at a distance of 750 km.

(F. A. Js.; X.)

SHADOW PLAY (SHADOW SHOW) is drama performed by flat, articulated puppets whose shadows are cast on a translucent paper or cloth screen illuminated from behind.

Shadow plays originated in the Orient. In India, subjects were drawn from the Hindu national epics *Mahabharata* and *Ramayana* (*qq.v.*). These passed to Java where they developed into a popular theatre which performed for all ceremonial occasions. Themes from Javanese legendary history and new ones introduced in the 15th century when Java became Muslim were also used. The figures, made from buffalo hide, were highly stylized, perforated, and painted. The narrator (*dalang*) operated the puppets (usually by thin bamboo rods), spoke their lines, and directed the orchestra. Bali received the shadow play from Java, gave the figures a characteristic stylization, and preserved the Indian themes. In Siam similar stories were presented, and the shadow theatre was also found in Malaya, Burma and Cambodia. The shadow play in China, for which a legendary origin in the Han dynasty is claimed, became a favourite entertainment for court ladies. The figures were made from thin donkey skin, dyed to cast brilliant colours on the screen.

Shadow plays spread westward by way of Persia to Turkey, where the witty and vulgar characters Karagöz and his companion Hadjivad became the heroes of a popular theatre. The puppets were made of camel hide, perforated and coloured to present types such as the opium addict and the idiot, as well as regional characters including the Persian, the Albanian, and the Jew. These plays became popular in Greece, where such showmen as Antonios Mollas gave them a Greek interpretation. Shadow plays were also found in the Muslim countries of northern Africa.

In the 17th century the shadow theatre was known in Italy; from there it spread to other western European countries. The French called them *ombres chinoises*, although they were black silhouettes, instead of coloured like those of the Chinese. Dominique Séraphin opened a shadow show in Versailles in 1774, later moving it to the Palais Royal in Paris. Until 1859 his descendants presented specially written plays, such as *The Broken Bridge*. Sophisticated plays were produced by a group of artists, musicians and writers who regularly met at the Chat Noir cabaret in Montmartre, Paris. Other cabarets imitated them, and shows were given until 1923.

Shadows were popular in America during the 18th century, declined toward its end, and were revived around 1880. At the Chicago World's Fair in 1893, Léon-Charles Marot presented the *Théâtre des Ombres Parisiennes*, similar to the performances of the Chat Noir. Greek emigrants brought their versions of the Karagöz plays to the U.S. where they were seen in Chicago and Detroit coffeehouses.

In modern times Pauline Benton produced shows in the U.S. with authentic Chinese shadows. After World War I, Lotte Reiniger developed in Germany a number of films in stop motion, using black silhouettes against backgrounds of varying tones of gray. Although showmen in Europe and the U.S. occasionally used them, shadow plays were less popular in the 1960s than in the past.

SHADWELL, THOMAS (?1641–1692), English dramatist and poet laureate, known for his broad comedies of manners, and as the butt of Dryden's satire, was born at Santon, Norfolk, probably in 1641. He went to Bury St. Edmund's Grammar School in 1655, and to Caius College, Cambridge, in 1656; and entered the Middle Temple in July 1658. After the Restoration he became one of the circle of "court wits" with Rochester, Sedley, and Etherege. In 1664 he spent four months in Ireland, but lived mainly in London, where he benefited from the patronage of the duke and duchess of Newcastle; he is thought to have had a hand in two of the duke's plays. He was also an acquaintance of Sir Robert Howard (*q.v.*) and his brother, Edward, both of whom he satirized in *The Sullen Lovers* (1668).

His friendship with John Dryden (*q.v.*) lasted until the political crisis of 1678–79, when Shadwell espoused the Whig cause with typical blunt aggressiveness, causing offense with the anti-papist propaganda of his play *The Lancashire Witches*. This was held up, partly as a result of Dryden's vigilant hostility, until the autumn of 1681, when an expurgated version was performed. Dryden's attack on Shadwell in *The Medall* (March 1682) was

answered in May by *The Medal of John Bayes:* it used to be thought that *Mac Flecknoe* was Dryden's answer; but this is now known to have been written by 1678. Shadwell continued to attack Dryden with *Satyr to his Muse* (July 1682) and *The Tory Poets* (September), and was satirized as Og in the second part of Dryden's *Absalom and Achitophel* (November). The Revolution of 1688 ousted Dryden from the laureateship in favour of Shadwell, who also became historiographer-royal. He took advantage of the change to obstruct Dryden, and in November 1690 succeeded in having his prologue to Thomas Betterton's *The Prophetess* prohibited. He was less successful with *Cleomenes, The Spartan Heroe,* which was held up on the eve of production (April 1692), but later performed. Shadwell died in London on Nov. 19, 1692.

As a comic dramatist, Shadwell claimed direct descent from Ben Jonson (*q.v.*), whose craft of "humours" he continued, often with considerable success. Though not as great as his master, he is always competent and often brilliant in characterization; he directs his plots with skill; and his prose dialogue is often lively. In general he paints a skilful picture of the Restoration scene. His verse is generally dull, its solidity unrelieved by harmony or elegance; even his translation of Juvenal's *Tenth Satyr* (1687) lacks bite. His official verse as laureate falls even below the mediocrity that has often characterized the output of holders of that office.

SHAFI'I, AL- (Abu 'Abdallah Mohammed ibn Idris al-Shafi'i) (767–820), one of the greatest jurists of Islam and the founder of the Shafi'i school of canon law, was born in A.H. 150 (A.D. 767) at Gaza or Ascalon, and was brought up by his mother in poor circumstances at Mecca. There, and especially in intercourse with the desert tribe of Hudhail, he gained a knowledge of classical Arabic and old Arabian poetry for which he was afterward famous. About 170 he went to Medina and studied canon law under Malik ibn Anas.

After the death of Malik in A.H. 179 legend takes al-Shafi'i to Yemen, where he is involved in a conspiracy on behalf of 'Ali, carried prisoner to Baghdad, but pardoned by Harun al-Rashid. He was certainly pursuing his studies, and he seems to have gone to Baghdad in some such way as this and then to have studied under teachers of the Hanafi school. He had not yet formulated his own system. After a journey to Egypt, however, he is reported in Baghdad again, as a teacher, between A.H. 195 and 198. There he had great success and turned the tide against the Hanafi school. In 198 he went to Egypt in the train of a new governor, and this time was received as the leading orthodox authority in law of his time. In Egypt he developed and somewhat changed the details of his system, and died in A.H. 204 (A.D. 820). He was buried to the southeast of what is now Cairo, and a great dome (erected *c.* A.D. 1211–12) is conspicuous over his tomb.

The "classical" theory of Islamic law, by which is meant the view that the law is based upon four sources (Koran, *sunna, ijma'*, *qiyas*), was, according to Joseph Schacht, the creation of Shafi'i. The classical theory does not fully explain the facts as unearthed by modern research. Whether the opinion of Schacht, in its full import, is correct has yet to be proved; but his researches are worthy of the most serious consideration, and they give an insight into the system developed by a master jurist. *See* also Islamic Law.

See Joseph Schacht, *Origins of Muhammadan Jurisprudence* (1950); *Shorter Encyclopaedia of Islam,* pp. 512–515 (1953). (A. A.-A. F.)

SHAFT, DRIVING. A driving shaft is a cylindrical, rotating member which transmits motion or power, usually both, from one point to another. The shaft may be made of any material strong enough for the purpose, but nearly all shafts are made of metal, especially steel. Motors, engines and machines of all kinds have shafts, often of a specialized kind, such as the camshaft and crankshaft in an automotive engine. In general, the input to or the output from a shaft may be through a shaft coupling, of which there are various kinds, or through belt-driven pulleys, chain drives, gears, etc. The crankshaft of an automotive engine receives power from the work done by the expanding gases in the cylinder; the camshaft is driven from the crankshaft by gears or a chain and delivers power through the cams that operate the valves.

A line shaft drives more than one machine and is itself driven by a prime mover, the power being taken off via belts or chains, usually at several points along the shaft. Shafts intermediate between a line shaft and a driven machine are variously called countershafts, jackshafts or headshafts. In highly industrialized areas where electricity is readily available the use of individual motor drives for each machine is generally favoured over line shafts. It is common practice to speak of short shafts on machines as spindles, especially shafts that carry cutting tools on metal-working machines. The word axle strictly refers to a stationary member carrying rotating wheels, pulleys, etc., as the axle on a wagon or wheelbarrow; but the drive shafts to the rear wheels of an automobile are also called axles, no doubt a carry-over from horse-and-buggy days.

A shaft is designed to carry without failure or without excessive deformation the forces which act upon it. These forces may cause the shaft to bend, inducing what are called bending stresses within the material, or cause the shaft to twist, inducing twisting or torsional stresses; more often than not, shafts are subject to both bending and twisting forces. Sometimes a force acting in the axial direction causes a tensile or compressive stress. In accordance with theory, these stresses combine and if the resultant combination is too large, the strength of the material will be exceeded and the shaft will fail. Most shafts break because the resultant of the combination of stresses at some point repeatedly exceeds the fatigue strength of the material. The stress at a point is increased by discontinuities such as fillets, etc.

It is quite likely that the breaking strength of a shaft is not the significant criterion. In a large percentage of situations, it is a matter of keeping the deflection of the shaft at a specified minimum. For example, in machine tools, rigidity or resistance to deflection is most important if the machine is to cut metal to close tolerances. This is often true even if the amount of deflection involved is much too small for the unaided eye to perceive. The torsional deflection of most machinery shafts will be less than 0.1° per foot of length. The transverse or bending deflection may be from a few ten-thousandths of an inch, depending upon the requirements. If the transverse deflection is large enough, a shaft may tend to bind in its bearings.

Any rotating shaft has a critical speed at which the shaft vibrates noticeably, perhaps violently. It might be said that at the critical speed the shaft is undecided whether to rotate about its geometric axis or about the axis through its centre of mass and it attempts to do both. This speed can be fairly accurately computed for a given situation; in any case, the shaft must be designed to run either well above or well below the critical speed.

Flexible shafts will bend around obstructions, as a cable bends, or will transmit small amounts of power in a curved form. They are used in dentists' grinding tools, portable drilling and polishing machines, etc.

Shafts are manufactured by cold-rolling or cold-drawing, processes which leave a relatively hard, strong, smooth surface on steel. Because of the residual stresses left within the metal after cold-working, cold-finished shafts will warp when a keyway is cut and must later be straightened. Larger shafts are made from hot-rolled steel, turned on a lathe and polished or ground.
(V. M. F.)

SHAFTESBURY, ANTHONY ASHLEY COOPER, 1st Earl of (1621–1683), English politician who was one of the most prominent and skilful opponents of Charles II's pro-Catholic policy. He was born at Wimborne St. Giles, Dorset, on July 22, 1621, and succeeded his father, Sir John Cooper, as 2nd baronet on March 23, 1631. Largely through his mother, Anne (d. 1628), daughter and heiress of Sir Anthony Ashley, he inherited great estates in the southwest of England, and, although much was lost during his long minority, he remained a wealthy man. Educated partly by tutors, partly at Exeter College, Oxford, and partly at

Lincoln's Inn, he early showed evidence of a restless and acute intelligence, which led to his return to the Short Parliament of 1640 as member for Tewkesbury, Gloucestershire, and in December to the succeeding Long Parliament as member for Downton, Wiltshire. As he was still under age, however, and as his election to the Long Parliament was the subject of a dispute that was not determined until 1660, it seems unlikely that he played any effective part in either Parliament.

DETAIL OF A PORTRAIT BY AN UNKNOWN ARTIST, ABOUT 1672–73; PHOTO, BY COURTESY OF THE NATIONAL PORTRAIT GALLERY

THE 1ST EARL OF SHAFTESBURY, ANTHONY ASHLEY COOPER

Civil War and Commonwealth.—His first marriage, on Feb. 25, 1639, to Margaret, daughter of Thomas, 1st baron Coventry, the lord keeper of England, confirmed his natural inclination to take the royalist side in the English Civil War. Early in 1644, however, he went over to Parliament and took an active part in the concluding stages of the war in the southwest. Thereafter he devoted himself mainly to the problems of local government until appointed a member of the Barebones Parliament in 1653 and returned for Wiltshire to the Parliaments in 1654, 1656, and 1659.

Appointed a member of the Council of State on July 14, 1653, and, after Oliver Cromwell became lord protector, of its successor, the Lord Protector's Council, on Dec. 16 of the same year, he supported Cromwell for some time and opposed the more extreme reformers. At the very end of 1654, however, alienated by the protector's increasing neglect of Parliament, he broke away from him, and in consequence was one of the members denied the certificate from the council without which they could not take their seats in the Parliament of 1656. He strongly protested, the certificates were soon afterward abolished, and he took his seat; but he was not elevated, as in other circumstances he probably would have been, to the new "House of Lords" created in 1657. When his criticisms of that House and of the protector's autocratic methods proved unavailing, he continued his opposition, both for the remainder of Oliver Cromwell's life and under Richard Cromwell.

Restoration of Charles II.—After Richard's fall and the restoration of the Rump of the Long Parliament (May 1659) he was reappointed to the Council of State and came under increasing suspicion of favouring the exiled Charles II. Against the power of the army he upheld the authority of Parliament; but it was a genuine Parliament that he had in mind, and he lent all his weight to secure first his own right to sit in virtue of his election in 1640, then the readmission (December 1659) of the members excluded by Pride's Purge in 1648 and finally the dissolution of the Long Parliament (March 1660) and the election of a new one (the Convention Parliament). Returned to that parliament as member for Wiltshire, he exerted himself to secure the recall of Charles II. On May 7 he was appointed one of the 12 commissioners sent by the Commons to Breda in Holland to invite Charles to return, and after the landing of the king at Dover on May 25 he waited on him at Canterbury and was well received.

Offices and titles were immediately conferred upon him. Admitted to the Privy Council on May 27 and to the Committee for Plantations on July 4, 1660, he was created Baron Ashley of Wimborne St. Giles on April 20, 1661, and appointed chancellor of the exchequer on May 13 of the same year. In the general settlement that followed the return of the king he advocated a policy of moderation, urging lenity toward the "regicides," opposing the more extravagant provisions of the so-called Clarendon Code, and supporting Charles II's declaration of 1662 in favour of toleration. Charles was impressed by his industry and ability, and on the death of the earl of Southampton, the lord treasurer, in May 1667 he was appointed to the commission that took Southampton's place, soon becoming its most influential member.

During these years he developed a deep interest in the problems of commerce and colonization. Part owner of a plantation in Barbados, and member of several committees dealing with colonial affairs under the Commonwealth, he had served a long apprenticeship in the colonial field and was now regularly included in the various committees to which such affairs were entrusted. On March 24, 1663, he was given a grant, along with seven others, of the vast province of Carolina in North America, and found in it an ideal field for experimentation. Making the acquaintance, three years later, of the philosopher John Locke, he entrusted him with the task of drawing up a constitution for the province based upon aristocratic predominance, religious toleration, and other principles he would have liked to see recognized in England. In October 1673 he secured for Locke the position of secretary to the recently established Council of Trade and Foreign Plantations, of which he himself had been appointed president in September 1672.

Meanwhile Ashley's position at court had first improved and then suddenly declined. On the dismissal and impeachment of the earl of Clarendon in 1667 he had attached himself to the duke of Buckingham, with whom he had a common interest in the support of religious toleration. As early as 1670 he became so impressed by the danger of the Catholic James, duke of York (later James II), succeeding to the throne as to give his support to schemes for securing a divorce for the king or legitimizing his bastard son, James, duke of Monmouth. He was therefore excluded from the secret of the real Treaty of Dover (1670), which aimed at the reconversion of England to the Roman Catholic faith. He approved of the sham treaty, which provided only for an Anglo-French alliance to reduce the commercial supremacy of the Dutch, and readily signed it, along with other members of the so-called Cabal, on Dec. 21, 1670.

As a reward he was appointed lord lieutenant of Dorset on Jan. 20, 1672, created earl of Shaftesbury on April 23, and appointed lord chancellor on Nov. 17. As chancellor he was, by general admission, a success; but in his capacity of adviser to the king he was now in a false position, for he was advocating a policy half of which was concealed from him. When Parliament assembled in Feb. 1673 he delivered his famous *"Delenda est Carthago"* speech, justifying the attack on the Dutch as the commercial rivals of England; but as he watched the rising tide of opposition to the king's policy, and began to suspect that there was more in that policy than he had been given to understand, his attitude inevitably changed. Later in the same year he supported the first Test Act, designed to exclude Roman Catholics from office under the crown, and did his best in Parliament to oppose the duke of York's marriage with the Catholic Mary of Modena. On Nov. 9 he was summarily dismissed from the chancellorship and went into opposition. On May 19, 1674, he was also dismissed from the Privy Council and from his local offices.

In Opposition.—It is as a leader of opposition to the court that Shaftesbury is chiefly remembered, but real leadership of the malcontent elements in Parliament and the country long evaded his grasp. His frequent changes of policy and his inclination toward extreme courses were regarded with disfavour by responsible men, and even among his own associates some preferred the leadership of Lord Holles. Successful in obstructing the earl of Danby's nonresisting test bill in the spring of 1675, he failed in the autumn of the same year, even with the assistance of the duke of York, to carry in the Lords an address in favour of a dissolution of the Cavalier Parliament. He then sought supporters among discontented elements in the City of London, elaborated an argument that, in accordance with a statute of Edward III's reign requiring annual Parliaments, a prorogation for 15 months pronounced on Nov. 22, 1675, was in effect a dissolution, and advanced this contention in the Lords when the Houses reassembled on Feb. 15, 1677. He was immediately sent to the Tower of London by the Lords themselves and was not released until Feb. 26, 1678.

The event that gave him his real chance was the appearance of

Titus Oates in the autumn of 1678 with his story of a vast "popish plot" against the king and government. Shaftesbury was in no sense the originator of the tale told by Oates, and indeed began by regarding it with suspicion as a fable inspired by government supporters with the object of rallying the nation round the king; but he soon realized what a useful weapon it might prove in his hands, and thereafter he supported it to the utmost. In the nationwide panic that it engendered, moderate leaders and counsels were forgotten and he was able to secure widespread acceptance as the only man with the courage and skill to ride the storm. By developing an elaborate party organization, based on the famous Green Ribbon Club, he exercised great control over elections, built up a large following both in the Lords and in the Commons, and in three successive Parliaments (1679, 1680, and 1681) endeavoured to secure the exclusion of the duke of York from the succession to the throne. To his efforts at this time was largely due the passing of the Habeas Corpus Act (May 1679), perhaps his greatest and most creditable achievement.

Exclusion Crisis.—With the object of silencing him by giving him a high office Charles on April 21, 1679, remodeled the Privy Council, admitted many of the leading members of the opposition to it, and appointed Shaftesbury president; but the king's failure to follow the advice of his new council soon led Shaftesbury to withdraw his support, and on Oct. 15 of the same year he was dismissed. On Nov. 15, 1680, the Exclusion Bill, which had passed without a division in the Commons, was rejected by the Lords, in spite of some brilliant speeches on his part; this only inspired him to more violent courses. To the succeeding Parliament, which met at Oxford on March 21, 1681, he and his associates rode with an armed following, confident that the king, in his need of money, could not withstand the pressure of the House of Commons any longer. Charles, however, who had just strengthened his financial position by an agreement for a subsidy from Louis XIV of France, dissolved Parliament within a week, and Shaftesbury suddenly found himself practically helpless. Unfortunately the policy by which he had secured his acceptance as the oracle of the nation had almost inevitably been marked by extravagance rather than by statesmanship, and as the panic caused by the "popish plot" declined, his credit had correspondingly diminished. Complete exclusion of the duke of York was a hazardous device which could have been accepted, if at all, only during a moment of panic. The substitution of the duke of Monmouth, at which he aimed, probably could not have been accepted at any time, and was only too obviously inspired by his desire to have on the throne a mere puppet of his own. On the unexpected dissolution of the 1681 Parliament therefore, his following simply disintegrated, and he himself came into a position of considerable danger.

Trial and Flight.—For the short remainder of his life his chief efforts were directed toward his own safety. On July 2, 1681, he was seized, committed to the Tower, and kept there for four months while every effort was made to find or suborn evidence on which to base a charge of high treason against him. So gloomy did his prospects appear that he offered, if released, to retire to Carolina. At his trial on Nov. 24, however, the Whig grand jury selected by the Whig sheriffs of London rejected the indictment, and on Dec. 1 he had to be admitted to bail, from which in turn he was released on Feb. 13, 1682. But the court was in the ascendant, and at the midsummer election contrived to secure the return of two Tory sheriffs for London. Thus deprived of all prospect of protection from a favourable jury at a future trial, Shaftesbury made desperate efforts to organize a rising against the government, and when these proved vain left the country on Nov. 28. Reaching Amsterdam early in December he was granted asylum there and admitted a burgher; but imprisonment and privations had aggravated the diseases from which he had long suffered, and after a short final illness he died in Amsterdam on Jan. 21, 1683. His body was brought back to England, and was buried at Wimborne St. Giles.

Shaftesbury was undoubtedly a very clever man, and particularly adept at turning to his own advantage the weaknesses of others; but he failed to realize that in English politics cleverness alone is not enough, and that men are not composed exclusively of weaknesses. He has been credited with few genuine principles beyond a sincere belief in Parliament and in the desirability of toleration in religious matters. His methods are difficult to defend, involving as they usually did not merely an assumption that the end justifies the means but also a reckless disregard of future consequences in the prospect of immediate gain. Especially toward the close of his life he repeatedly embarked on courses which men much less acute than he was could see were bound to lead to disaster. It is typical of his whole career that he ended his life under the protection of the Dutch, the nation which he had done his best, when at the height of his power, to ruin.

Bibliography.—*The Shaftesbury Papers*, consisting of autobiographical fragments, letters, speeches and documents connected with Shaftesbury's colonial ventures, are in the Public Record Office, London. Many of them are printed in W. D. Christie, *A Life of Anthony Ashley Cooper, First Earl of Shaftesbury*, 2 vol. (1871), which is still the standard biography. H. D. Traill, *Shaftesbury* (1886), and O. Airy's article in the *Dictionary of National Biography* are useful sketches, one unfavourable and the other favourable in its interpretation of Shaftesbury's conduct. L. F. Brown, *The First Earl of Shaftesbury* (1933), devotes attention to his connection with commercial and colonial developments. (A. Bc.)

SHAFTESBURY, ANTHONY ASHLEY COOPER, 3rd Earl of (1671–1713), English politician and philosophical writer, was born at Exeter House, London, on Feb. 26, 1671, the son of Anthony (afterward 2nd earl of Shaftesbury) and grandson of the famous 1st earl (*q.v.*). His early education was directed by the philosopher John Locke. In 1683 he went to Winchester College and in 1686, with a tutor, he toured France, Italy, and Germany, returning to England shortly after the Revolution of 1688. He entered Parliament for Poole, in Dorset, at a by-election in 1695, but his health, never robust, broke down and after the dissolution of 1698 he did not return to the House of Commons.

During a debate in the Commons in 1695 he spoke in favour of a bill to allow counsel to assist those accused of high treason. Too overcome by the occasion to recollect the points he had prepared, he was yet able to make out of his own confusion a powerful argument in support of the bill. "If I," he declared, ". . . am so confounded that I am unable to express the least of what I proposed to say, what must the condition of the man be who is pleading for his life without any assistance?" The bill was passed and became the celebrated Trial of Treasons Act of 1696.

Succeeding as 3rd earl in 1699, in the quieter atmosphere of the House of Lords he was able to attend Parliament regularly for the remainder of William III's reign. He pursued an independent policy, as he had done in the Commons, though his general outlook was that of an advanced Whig. Offered high office, he accepted (June 1701) only the vice-admiralty of Dorset, but after the Tories came to power on the accession of Queen Anne (March 1702) he was deprived of the office in July 1702 and retired from public life.

Having spent most of 1699 in Holland, where the climate suited him better, he now returned there on a further visit (August 1703–August 1704). He was, however, to be an invalid for the rest of his life, and his health again forced him to go abroad in July 1711. He died in Naples on Feb. 15, 1713. He had married Jane Ewer in 1709 and his son Anthony, the 4th earl, was born in 1711.

Shaftesbury's philosophy owed something to the Cambridge Platonists (*q.v.*), who had stressed the existence in man of a natural moral sense. Shaftesbury was at pains to put forward this concept, both against the orthodox Christian doctrine of the Fall and against Hobbes's premise that the state of nature was a state of unavoidable warfare. Against Hobbes's conception of "solitary" man, Shaftesbury maintained that man is essentially social; that his mind (in some degree part of the governing mind of the Creator) is so imbued with the principles of unity and proportion that he can adequately balance the claims of self affection (tending to a private good) with those of natural affection (tending to the public good), while rejecting those of unnatural affection (which furthers neither private nor public happiness). Thus, instead of Hobbes's solution of the setting up of the absolute authority of a Leviathan to maintain order, Shaftesbury contended that this could be achieved by a "right Division and Ballance of Power and

by the Restraint of Good Laws and Limitations."

In his stress upon the natural, Shaftesbury was not a forerunner of the primitivists who exaggeratedly revered the "noble savage"; for him the term had a teleological sense, for he considered the natural state of man to be that in which his faculties were most fully developed.

Shaftesbury also criticized revealed religion for its dependence on the miraculous, which, essentially contravening natural order, thereby insulted the dignity of creation. He also disliked the concept of reward and punishment epitomized in the doctrine of heaven and hell; he maintained that virtuous actions, being more truly pleasant than selfish ones, are therefore literally their own reward. He regarded evil as more apparent than real, explaining those events or tendencies which appear evil to man, as in reality facets of the divine scheme of things which man's limited vision prevents his seeing in their proper perspective.

Shaftesbury's Neoplatonism, his contention that what man sees of beauty or truth is only a shadow of absolute beauty or truth, also dominated his attitude to the arts. Akin to man's innate moral sense is his natural aesthetic sense; but Shaftesbury, in accordance with his view that natural means most fully developed, conceded that taste needs to be trained.

During his lifetime Shaftesbury's fame as a writer was comparatively slight, for he published little before the appearance in 1711 of his *Characteristicks of Men, Manners, Opinions, Times*, in which his chief works were gathered together. The effect of this book was immediate and was felt on the Continent as well as in England. Pope, Joseph Butler, Francis Hutcheson, Mark Akenside, Coleridge, and Kant (*qq.v.*) were among the writers to some degrees affected by Shaftesbury; and his literary criticism did much to form Augustan taste. *See* also ETHICS, HISTORY OF: *Modern Ethics*.

BIBLIOGRAPHY.—A large collection of documents connected with Shaftesbury is among the *Shaftesbury Papers* in the Public Record Office. The best edition of his *Characteristicks* is that of J. M. Robertson, 2 vol. (1900). Various of his letters, originally issued separately, were published in one volume, *Letters of the Earl of Shaftesbury, Author of the Characteristicks* (1746); supplementary writings, mainly concerning art, are in *Second Characteristicks; or, the Language of Form*, ed. by B. Rand (1914). See also the account of Shaftesbury's life, written by his son, *The Life, Unpublished Letters and Philosophical Regimen of . . . Shaftesbury*, ed. by B. Rand (1900); T. Fowler, *Shaftesbury and Hutcheson* (1882); R. L. Brett, *The Third Earl of Shaftesbury: a Study in Eighteenth-Century Literary Theory* (1951); B. Willey, *The Eighteenth Century Background* (1940); E. Wolff, *Shaftesbury und seine Bedeutung für die englische Literatur des 18. Jhs.* (1960). (A. Bo.; X.)

SHAFTESBURY, ANTHONY ASHLEY COOPER, 7TH EARL OF (1801–1885), English philanthropist, and the most famous advocate of social reform in 19th-century England, was born in London on April 28, 1801. He was the eldest son of Cropley, a younger brother of the 5th earl of Shaftesbury, and of Anne, daughter of the 4th duke of Marlborough. He became Lord Ashley when his father succeeded to the earldom in 1811, was educated at Harrow and Christ Church, Oxford, and entered Parliament in 1826. He succeeded his father as earl in 1851.

Although giving general support to the Conservatives, Ashley was always prepared to follow an independent line of action. He opposed the Reform Bill of 1832, but had been a supporter of Catholic emancipation, and his objection to the continuance of resistance to the abolition of the Corn Laws led him, in 1846, to resign his seat for Dorset which he had represented since 1831; he was returned to Parliament for the city of Bath in 1847. His parliamentary conduct was strongly influenced by his evangelical Christianity. He told his biographer that he believed that a man's religion, "if it is worth anything, should enter into every sphere of life, and rule his conduct in every relation." Religion counted with him far more than ambition and led him to devote his parliamentary life to the promotion of social reform. His efforts were concentrated on four objectives—improvement of conditions in lunatic asylums, factory reform, regulation of working conditions in coal mines, and public health.

Ashley delivered his first speech in the House of Commons on the subject of lunatic asylums in 1828. "By God's blessing," he wrote, "my first effort has been for the advancement of human happiness." The reward of this effort came in 1845 when the Lunacy Act of that year for the first time considered lunatics not as social outcasts but as "persons of unsound mind." He became associated with the cause of factory reform in 1832 when a deputation of northern factory reformers asked him to act as their spokesman in the Commons. He took the place of Michael Sadler (advocate of factory reform who died in 1835) and, like Sadler, supported the textile operatives' demand for a statutory limitation of the working hours for women and children in the factories.

Ashley was a lord of the admiralty (1834–35) under Sir Robert Peel, but, unable to obtain Peel's support for the Ten Hours' Bill, he refused to join Peel's administration in 1841. Chiefly by his persistent efforts a Ten Hours' Bill was carried in 1847, but its operation was impeded by legal difficulties, which were only removed by successive acts, instigated chiefly by him, until the law was consolidated by the Factory Act of 1874. During this long struggle his main parliamentary opponent was John Bright (*q.v.*), who opposed all factory legislation. Bright accused Ashley on more than one occasion not only of ignorance of the actual working conditions in the factories but of a lack of concern for rural workers, including those on his own father's estates.

The part Ashley took in the legislation bearing on coal mines was equally prominent, and the opposition he faced from the mine owners was as strong as that he had faced from the factory owners. The result of his initiative was the Mines Act of 1842, which excluded from the coal mines all women and girls, all boys under 13, and all parish apprentices. His main speech in sponsoring the bill was so moving that Richard Cobden, one of his opponents on factory reform, crossed the floor of the house and told him that he had never in the course of his life "been put into such a frame of mind . . . as I have been by your speech."

Ashley's interest in public health brought him new allies as well as more implacable opponents. In 1841, when he was crusading for factory and mine reform, he was taken by a friend to see one of the dingiest and most sordid areas of London's East End. The visit left a deep impression on him and he became an active supporter of national legislation to control health conditions. He welcomed the first national Public Health Act of 1848 and became one of the members of the new General Board of Health set up under the act. He deplored the bitter opposition which led to the dissolution of the board in 1854.

Unlike some of his allies in the struggle for public health, Ashley was keenly concerned about the provision of adequate housing as well as the supply of water and the disposal of nuisances. One of his last acts before leaving the Commons for the House of Lords in 1851 was to introduce bills to encourage the establishment of lodging houses for the working classes and to enforce government inspection and regulation of such houses already in existence. Dickens hailed these measures as among the most altruistic of his age. Shaftesbury continued to take an interest in housing and on his 83rd birthday in 1884 gave evidence before the royal commission on the housing of the working classes. He was also keenly interested in education, particularly the religious education of poor children, and by his zeal gave a new impulse to the movement for the establishment of free schools for destitute children, commonly called ragged schools. For almost 40 years he was president of the Ragged School Union. He was also one of the principal founders of reformatory and refuge unions, Young Men's Christian Associations and Workingmen's Institutes. He supported foreign missions and was president of several philanthropic and religious societies. He was acknowledged leader of the evangelical group within the Church of England, and an outspoken critic both of ritualism and broad church liberalism.

Shaftesbury died on Oct. 1, 1885, at Folkestone.

SHAFTESBURY, a market town and municipal borough in the North Dorset parliamentary division of Dorsetshire, Eng., 20 mi. WSW from Salisbury by road. Pop. (1961) 3,372. Area 1.7 sq.mi. (4 sq.km.). It lies high on a hill, on the edge of Cranborne

Chase, above a rich agricultural district. Although traces of British and Roman occupation occur in the neighbourhood, the site of Shaftesbury (Caer Palladur, Caer Septon, Seaftonia, Sceafstesbyrig, Shafton) was probably first occupied in Saxon times. Matthew Paris speaks of its foundation by the mythical king Rudhudibras, while Asser ascribes it to Alfred, who made his daughter Ethelgeofu the first abbess. It is probable that a small religious house had existed there before the time of Alfred, and that it and the town were destroyed by the Danes, both being rebuilt about 888. The foundations of the Saxon abbey and nunnery have been laid bare. In 980 Dunstan took St. Edward's body there from Wareham for burial, and there Canute died in 1035. The relics of St. Edward were discovered in 1931 during excavation.

In 1252 the burgesses received their first charter from Henry III. There is no evidence that Elizabeth I granted Shaftesbury a charter as has been asserted, but she confiscated the common lands in 1585, the town only recovering them by purchase. This probably led to the granting of a new charter by James I in 1604. Yet another charter was granted to the town in 1684. Shaftesbury returned two members to parliament from 1294 to 1832, when the representation was reduced to one, and it was lost in 1885.

SHAFT SINKING. A shaft is a throatlike vertical or somewhat inclined excavation that penetrates downward into the earth's crust. Although shafts sometimes may be used as intermediate accessways along the courses of railway and vehicular tunnels, or for making deep footings of large buildings and dams and for establishing bridge piers, subways and similar structures, by far the greater number are sunk for underground mining of mineral deposits that cannot be reached by horizontal adits, or tunnels. The process of shaft sinking has been pursued in one way or another ever since man first began to do underground mining.

Subsurface mineral deposits are notably distinctive and often peculiarly unique so far as their mode of occurrence is concerned (*see* ORE DEPOSITS) and these characteristics frequently introduce important modifying elements in the nature and type of shaft that is made for their exploitation. That is, the shaft may prove to be the limiting "bottleneck" of a given mining operation if it has not been properly designed as to shape, size, depth and inclination to meet the particular environmental conditions that affect the ore body in question. Such situations often transpire because it is through the more or less constricted shaft opening that not only must the ore be moved but, also, all supplies, men and mining

FIG. 2.—SHAFT MUCKER USING POWER SHOVEL PRINCIPLE

equipment must be transported. Shafts may range in general type from crude openings to highly specialized and well-constructed excavations, and the several ways of shaft sinking may be of various degrees of complexity and engineering refinement.

The basic cycle of the shaft-sinking operation is similar to that which obtains to most mining ventures, namely: (1) drilling and blasting (breaking); (2) loading (mucking); (3) placing of timbers or other types of wall-support materials; and (4) hoisting.

These activities are interrelated in their application and, to be followed efficiently, they require the energy of co-ordinated mining crews. The several individuals forming a crew must have the faculty of working in close and safety-conscious co-operation, not only with each other but also with supporting associates whose function is to give service to the endeavour as a whole. The physical effort that must be expended ordinarily is great and the space within which the work must be performed is constricted. It often is very wet and of rather high temperature.

At about the beginning of the 20th century, the "breaking" stage of the mining cycle was marked by the progressive perfection and adoption of rock-drilling machines (*see* DRILLING MACHINERY) and this trend, accompanied as it was by the development of better explosives, contributed appreciable progress to the practice of shaft sinking. Most drilling machines are motivated by compressed air and during operation they either are hand-held or more commonly are mounted on a frame known as a "jumbo."

A typical drill hole pattern usually is composed of numerous downward directed holes. The explosives that are employed for blasting generally are water-repellant varieties of high-strength dynamites.

The arduous and expensive procedures of hand-loading and of

"mucking off the rough" were practised for many years after the advent of air-driven drilling machines and therefore the operational cycle of shaft sinking in reality showed but little refinement of consequence until about the time of World War II. That is, from the time when man first began to burrow extensively into the earth until the late 1930s, shafts to be used for mining purposes were sunk almost wholly by hand-labour methods or by a borehole drill rig of some form. In fact, sinking by borehole drilling was not used to noteworthy degree until about 1925.

However, mechanized mucking procedures have been pronouncedly advanced and few shafts are sunk without employing some type of mechanical means of loading. The more widely used and generally accepted types of equipment would fit into the following classification: scraper with 2- or 3-drum hoist (inclined shafts); reverse-action bucket or scoop on sliding boom (inclined shafts) (fig. 1); positive-action power shovel (fig. 2); overshot loader or "rocker shovel"; free-moving clamshell or orange-peel bucket loader; positive-action clamshell unit; and positive-action "backhoe" loader.

Most loading devices discharge into a pan or directly into a car or sinking-bucket sometimes called a "can" and the broken rock thus may be moved at will from the shaft chamber. Except for a few cases, shafts are lined with wood timbering (fig. 2) or with steel or concrete or masonry bricking. The shaft linings are so placed as to serve as protective walls to inhibit the infall of rock from the sides of the excavation and, also, they tend to reduce or to control the inflow of water. In addition, they afford means whereby running guides for the cages can be affixed and aligned.

In giving consideration to the adoption of a shaft-sinking process there are a number of factors that require analysis. First is the question of whether the shaft is to serve chiefly as a means of exploration and prospecting or is to be a large excavation dug so that a major ore body can be mined. Other factors which may bear consequential influence are: (1) availability and degree of skill of man power; (2) location, such as accessibility to sources of power and other supplies; (3) character of surface-plant site, especially with regard to the disposal of muck and the installation of the hoisting engine; and (4) prevailing geologic features and other conditions of the rock environment. This latter factor is particularly pertinent with reference to the shape and general attitude of the body to be exploited. Also, it is related to the existence of possible structures and other ground conditions which, by their influence on rock stability, may tend to induce problems bearing directly on the actual sinking operation.

BY COURTESY OF INTERNATIONAL NICKEL COMPANY

FIG. 3.—DRILLING BY SHAFT-SINKING CREW

There are usually other more incidental elements that must be analyzed. For example, if abnormally heavy water flows are encountered, they often will require the installing of exceptional pumping units or, at least, the building of eavelike ducts called "water rings" at intervals within the shaft. In addition, if the temperature gradient of the earth is steep, it is frequently necessary to furnish cooling and ventilating in a manner and to a degree that otherwise would not be needed.

Where the rock material to be penetrated is loose soil or gravel it may be grouted (cemented) or even frozen before sinking is begun.

In some cases, it is necessary to progress downward by lowering steel caissons or to push or drive wooden planks, called "spiles" or "forepoles," into the rock mass ahead of and beyond the actual excavation. These several practices have the general effect of inhibiting sloughing when the shaft is being made and, also, they usually serve to reduce the lateral percolation and undesirable inflow of subsurface water.

When hard rocks are being excavated, the normal or downward sinking cycle of drilling, blasting, mucking and hoisting ordinarily is followed. However, as before noted, the development of some shafts by various means of borehole drilling or, in some special cases, by "raising," which is a mining process carried upward from below, has proved to be outstandingly economic and efficient.

The operational plant unit needed to accomplish the shaft-sinking work usually is comprised of a hoisting engine and headframe, several buckets or skips, one or more sinking pumps, a satisfactory complement of drilling machines, ventilating fans, a selected loading machine and other accessory items of equipment and structure such as a change house and warehouse. Shaft-sinking costs may run to several hundred dollars a foot.

SHAHABAD, a district in Bihar, India, lies in the angle formed by the Ganges and the Son, and is divided from Uttar Pradesh by the Karamnasa. Area 4,408 sq.mi. (11,416 sq.km.). Pop. (1961) 3,218,017. To the north is an alluvial plain, closely cultivated and thickly populated, constituting about three-quarters of the district. The plain is watered by the Son Canals which irrigate more than 400,000 ac. (161,880 ha.); a further 250,000 ac. is irrigated from other sources. The southern part of Shahabad is occupied by the 1,000-ft.-high (305 m.), undulating, and forested Kaimur Plateau of sandstones underlain by limestone beds along the Son. The chief crops of the district are rice, gram, wheat, oilseeds, barley, and sugarcane. The Grand Trunk Road, the main line of the Eastern Railway, and the Grand Chord line pass through Shahabad, and there are two narrow-gauge railways—one linking Arrah and Sasaram (*qq.v.*) and the other Dehri and Rohtasgarh. Shahabad is also known as Bhojpur, which has given its name to a dialect of the Bihari language. The headquarters of the district is at Arrah. Because of its good communications and its proximity to the limestone beds and to the coal of the Damodar Valley Dehri (pop. [1961] 38,092) has emerged as a modern industrial town, manufacturing cement, sugar, paper, and chemicals. (E. AH.)

SHAH ALAM II (ALI GAUHAR; 1728–1806), nominal Mughal emperor of India from 1759 to 1806, was born on June 15, 1728, the son of the emperor Alamgir II. In 1758 Alamgir's vizier, Imad ul-Mulk (*see* ALAMGIR II), forced him to flee from Delhi to Shuja ud-Daula, nawab of Oudh. In 1759, after his father's assassination, he proclaimed himself emperor. Attempting, with the intention of making a bid for Delhi, to demand tribute from Bihar and Bengal, he came into conflict with the East India Company. After Shuja ud-Daula's defeat at Buxar in 1764, however, he became the company's pensionary, legalizing in return its position in Bengal, Bihar, and Orissa by the grant (1765) of the *diwani* (right of revenue collection). Though comfortably installed at Allahabad, Shah Alam hankered after Delhi, and in 1771 an agreement with the Marathas enabled him to return. During 1772–82, his minister, Najaf Khan, asserted imperial authority over a broad band of Delhi territory from the Sutlej to the Chambal and from Jaipur to the Ganges. In 1788 the Rohilla chief, Ghulam Kadir, seized Delhi and, enraged at his

failure to find treasure, blinded Shah Alam.

Bereft of all save dignity, Shah Alam spent his remaining years under the protection first of the Maratha chief, Sindhia, and then, after the Maratha war of 1803, of the British. He died at Delhi on Nov. 10, 1806.

See T. G. P. Spear, *Twilight of the Mughuls* (1951). (P. H.)

SHAHDOL, a town and district in the Rewa division of Madhya Pradesh, India, and the headquarters of the district of the same name. The town (pop. [1961] 22,196) is located on the Murna River, about 110 mi. (177 km.) NW of Bilaspur on the South Eastern Railway.

Shahdol District (area 5,412 sq.mi. [14,017 sq.km.]; pop. [1961] 829,649) extends across the Upper Son Valley between the Kaimur and Maikala ranges. About two-fifths of the area is forested and nearly one-third arable, rice and sesamum being grown. There are pottery works and cement factories at Kotma and Nowrozabad, and cardboard and lac factories at Umaria. Sohagpur is famous for its Virateshwar temple. Till its merger with Vindhya Pradesh in 1948, Shahdol district was under the authority of the Baghel rajas of Rewa state. (S. M. A.)

SHAH JAHAN (1592–1666), Mughal emperor of India from 1628 to 1658, builder of the Taj Mahal, was born at Lahore on Jan. 5, 1592. He was the third son of Jahangir (*q.v.*), his mother being a Rajput princess. Marrying in 1612 Arjumand Banu Begum, niece of Jahangir's wife Nur Jahan, he became, as Prince Khurram, one of the influential Nur Jahan clique of the middle period of Jahangir's reign. In 1622 Shah Jahan, ambitious to win the succession, rebelled, ineffectually circumambulating the empire until reconciled to Jahangir in 1625. After Jahangir's death in 1627, the support of Asaf Khan, Nur Jahan's brother, enabled Shah Jahan to proclaim himself emperor at Agra (February 1628).

His reign was notable for successes against the Deccan states. By 1636 Ahmednagar had been annexed and Golconda and Bijapur forced to become tributaries. There was also a temporary extension of Mughal power in the northwest. In 1638 the Persian governor of Kandahar, Ali Mardan Khan, surrendered that fortress to the Mughals. In 1646 Mughal forces occupied Badakhshan and Balkh. But Balkh was relinquished in 1647, and in 1649 the Persians reconquered Kandahar. (*See* further Aurangzeb.)

In September 1657 Shah Jahan fell ill, precipitating a struggle for succession among his four sons, Dara Shikuh, Murad Bakhsh, Shah Shujaʿ, and Aurangzeb. The victor, Aurangzeb, declared himself emperor in 1658 and strictly confined Shah Jahan in the Agra fort until his death there on Jan. 22, 1666.

Shah Jahan is famous for his buildings, preeminently for the Taj Mahal (*q.v.*), the tomb at Agra of Arjumand Banu, called Mumtaz Mahal (mother of Aurangzeb; d. 1631), but also for his new city at Delhi, Shahjahanabad (*see* Delhi). In religion, Shah Jahan was a more orthodox Muslim than Jahangir or Akbar but a less orthodox one than Aurangzeb.

See B. P. Saksena, *History of Shahjahan of Dihli* (1932). (P. H.)

SHAHJAHANPUR, a city in the Rohilkhand division of Uttar Pradesh, India, and the administrative headquarters of the district of the same name. Shahjahanpur lies on the left bank of the Deoha River (a tributary of the Ramganga) about 100 mi. (160 km.) NW of Lucknow, and is the site of a cantonment. Pop. (1961) 110,432. It was founded in 1647 during the reign of Shah Jahan by Nawab Bahadur Khan, a Pathan. His mosque is the only building of antiquarian interest. The city is a junction on the Northern Railway and is connected by metaled roads with Lucknow, Nainital, and Pilibhit. The main industries are the manufacture of sugar and oil, and carpet weaving.

Shahjahanpur District forms the southeastern part of Rohilkhand and consists of a long, narrow tract running up from the Ganges toward the Himalayas, and is for the most part level. Area 1,762 sq.mi. (4,564 sq.km.); pop. (1961) 1,130,256. The principal rivers are the Gomati (Gumti), Khanaut, Garai, and Ramganga. The main crops are sugarcane, rice, wheat, and barley. At Rosa, 4 mi. from Shahjahanpur city, there is a large sugar factory and at Lodhipur an important sugarcane research institute. (B. Si.)

SHAHRUKH (Shahrukh Mirza) (1377–1447), the fourth son of the Asian conqueror Timur (*q.v.*) and the first of the Timurid dynasty, was born at Samarkand on Aug. 20, 1377. During Timur's lifetime, Shahrukh played a conspicuous and gallant part in the empire's affairs and wars. As principal Timurid ruler in Iran from 1405 to 1447, he succeeded in restoring some order there, as he did in Transoxiana after the disturbances following his father's death. With the exception of Syria, he ruled at times an empire coterminous with that which Timur had founded. Azerbaijan and Baghdad, however, were subject to inroads from the Black Sheep Turkmens, who did not submit to Shahrukh till after the death of their leader, Kara Yusuf, in 1420. Shahrukh was a reluctant, though successful and brave, warrior; his glory lies in his patronage of the arts and of science. The library and the outburst of miniature painting at Herat, his chief residence, point to this. The tradition was continued, notably by his short-reigned, only surviving son, Ulugh Beg (1447–49). Shahrukh's wars were generally undertaken to settle quarrels between princes of his own house. But settlements thus imposed were temporary and the process which destroyed Timurid power in Iran was not halted. Shahrukh manifested the culture and the quasi-mystical elements latent in his father, who had insatiably devoted his energy to world conquest. Shahrukh maintained relations with China, a shadowy contact which influenced the development of miniature painting. His nominal suzerainty over India heralded his family's eventual revival of power on a stage other than Iran and Transoxiana (*see* Babur). Shahrukh died at Fishawand, Ray province, Iran, on March 12, 1447.

See also Persian History. (P. W. A.)

SHAIVISM: *see* Shivaism.

SHAJAPUR, a town in the Bhopal division of Madhya Pradesh, India, and the administrative headquarters of the district of the same name, lies on the Agra-Bombay road about 50 mi. (80 km.) N of Indore. Pop. (1961) 17,317. The town was founded in the 17th century by the emperor Shah Jahan, when it was called Shahjahanpur, the name being subsequently corrupted to Shajapur. A notable architectural feature is the well-preserved fort; this contains the palace of Tarabai which houses the district offices. The town's educational institutions include a degree college, a high school, and a girls' school.

Shajapur District is situated on the Malwa plateau with its characteristic rolling topography and black cotton soil. Area 2,388 sq.mi. (6,185 sq.km.); pop. (1961) 526,135. The people, who speak Malvi, a dialect of Hindi, are mainly engaged in agriculture, and the chief crops are millet, wheat, cotton, oilseeds, tobacco, and sugar. The district has some cotton ginning and pressing mills, and also oil mills. Other important towns are Agar (11,486) and Shujalpur (13,690), near which is a cenotaph commemorating Ranoji Sindhia, the founder of the state of Gwalior. Fine Jain temples and images are to be found at various places in the district. (D. G. Na.)

SHAKER HEIGHTS, a city of Ohio, U.S., is an attractive residential suburb of Cleveland (*q.v.*). Planned and developed by the Van Sweringen brothers after 1900 in an area once held by the North Union Shaker community, Shaker Heights was incorporated as a village in 1912 and as a city in 1931. After 1920 it was accessible to downtown Cleveland by rapid transit railroad, now city owned. Population increase, after the initial rush of the 1920s, was due to large apartment developments. In the 1960s little vacant land remained and building codes were rigid. There are no industries in the community. Shaker Heights has a top-ranking public-school system, excellent private schools, a public library and a Shaker historical museum. Shaker lakes, once the site of the Shaker community grist and woolen mills, furnish a distinctive setting for the suburb. For comparative population figures see table in Ohio: *Population.* (V. B. S.)

SHAKERS, a celibate communal society that originated in France in the late 17th century, developed in England, and reached its full flower in the United States in the late 18th and early 19th centuries. The Shakers are remembered for their arts and crafts, especially their beautiful furniture, and for the dance that was a part of their worship. *See* Utopia: *Shakers*.

SHAKESPEARE, WILLIAM (1564–1616), English player, playwright, and poet. Ben Jonson, his friend and fellow-dramatist, described Shakespeare as "not of an age, but for all time," and John Dryden, the greatest poet and dramatist of the age after Shakespeare's, spoke for succeeding ages in saying that he "had an Universal mind." Thus, though for a full understanding of Shakespeare, as man, poet, and playwright, it should be remembered that he was a middle-class Elizabethan Englishman, it is his outstanding quality of universality that has made him generally acknowledged as not only England's, but the world's, greatest poet and playwright.

This article is divided into the following main sections:

I. LIFE

1. Birth.—The first of the scanty records of Shakespeare's life is the entry of his baptism in Holy Trinity Church, Stratford-upon-Avon (*q.v.*), in Warwickshire, on April 26, 1564.

2. Ancestry and Origins.—His father, John Shakespeare, was a burgess of the recently constituted corporation of Stratford (it received its charter in 1553), and had already filled certain minor municipal offices. In 1561 and 1562 he was chosen as one of the two chamberlains to whom the finance of the town was entrusted. John Aubrey (*q.v.*), in his life of Shakespeare, written in 1681 and based partly on information given him by the son of the actor Christopher Beeston (*q.v.*), describes him as a butcher, and Nicholas Rowe (*q.v.*), in his *Life of Shakespeare* (1709), as a wool dealer, but it is clear from formal documents that he was a glover, or a "whittawer" (a craftsman who cured the skins used by the glover), although he appears to have dealt from time to time in various kinds of agricultural produce, such as barley, timber, and wool. He is also described as a yeoman, and it is possible that he combined farming with trade. He was living in Stratford as early as April 1552, when he was fined for having a "dunghill" (*i.e.*, rubbish dump) outside his house and shop in Henley Street, but he does not appear to have been a native of the town. He may reasonably be identified with a John Shakespeare of Snitterfield, who administered the estate of his father, Richard Shakespeare, in 1561. Snitterfield is a village near Stratford, and there Richard Shakespeare had been settled as a farmer since 1529.

It is probable that John Shakespeare carried on the farm for some time after his father's death, and possible that by 1570 he had acquired a smallholding called Ingon Meadow in Hampton Lucy. But the farm at Snitterfield seems to have passed subsequently to his brother Henry, who was buried there in 1596. Efforts have been made to trace Shakespeare's genealogy back beyond Richard Shakespeare of Snitterfield, but without success. Certain drafts of heraldic grants of the Shakespeare arms (granted in 1596, reconfirmed and extended in 1599; *see* below) speak in one case of John Shakespeare's grandfather, in another of his great-grandfather, as having been rewarded with lands and tenements in Warwickshire for service to Henry VII. No such grants have been traced; statements about "antiquity and service" in heraldic preambles were, even in the 16th century, looked upon with suspicion.

The name Shakespeare is widespread, and is spelled in an astonishing variety of ways. Paleographers hold that Shakespeare himself, in the six extant examples of his signature, generally wrote "Shakspere" in full or in an abbreviated form, but possibly, in the main signature to his will, "Shakspeare." In the printed signatures to the dedications of his poems, on the title pages of nearly all the contemporary editions of his plays that bear his name, and in many formal documents, it appears as "Shakespeare" or "Shake-speare." This may be in part due to the martial derivation which the poet's literary contemporaries were fond of assigning to his name (as, for example, Ben Jonson's pun on "shake a Lance" in his verses for the First Folio of 1623), and which is acknowledged in the arms he bore (*see* below). Certain forms often used at Stratford, however, such as Shaxpere and Schackspere, suggest a short pronunciation of the first syllable, and thus tend to support Henry Bradley's derivation (in the *Academy*, Feb. 5, 1887) from the Anglo-Saxon personal name, Seaxberht.

On his mother's side Shakespeare was connected with a family of some distinction. At least part of Richard Shakespeare's land at Snitterfield was held from Robert Arden of Wilmcote in the nearby parish of Aston Cantlow, probably a younger son of the Ardens of Park Hall, who were among the leading gentry of Warwickshire. In 1548 Robert Arden married as his second wife Agnes Hill, formerly Webbe; he was already the father of eight daughters by his first wife. To the youngest, Mary, when he died in 1556 he left a freehold farm called Asbies, at Aston Cantlow. He had possibly already settled other property in Wilmcote upon her. Mary, at some date later than November 1556, and probably before the end of 1557, married John Shakespeare, who had, in October 1556, bought two freehold houses in Stratford, one in Greenhill Street, the other in Henley Street. The latter, known as the wool shop, was the more easterly of the two houses which in 1857 were combined to form the property known as Shakespeare's Birthplace. The western house, locally regarded as the Birthplace proper, may already have been in John Shakespeare's hands in 1556, as he seems to have been living in Henley Street in 1552, the date of the prosecution referred to above.

William was not the first child. A Joan was baptized in 1558 and a Margaret in 1562. Margaret was buried in 1563, and Joan must have died young, though her burial is not recorded, as a second Joan was baptized in 1569. A Gilbert was baptized in 1566, an Anne in 1571, a Richard in 1574, and an Edmund in 1580. Anne died in 1579; Edmund (who, like his brother, became an actor) in 1607; Gilbert in 1612; Richard in 1613.

After his marriage John Shakespeare became prominent in Stratford life. In 1565 he was chosen as an alderman, and in 1568 he held the chief municipal office as bailiff. This carried with it the dignity of justice of the peace. He seems to have contemplated the assumption of arms, and usually appears in corporation documents as "Master" Shakespeare.

3. Education.—Shakespeare, therefore, is to be thought of as the son of a leading citizen of an important market town. Stratford stands in agricultural country throughout which enclosed orchards and meadows alternate with open arable fields; not far distant is the wilder wooded district of the Forest of Arden (*q.v.*). Among Stratford's medieval heritages was a free grammar school; and here it is natural to suppose that he obtained a sound education, with a working knowledge of Virgil and Ovid in the original Latin, even though to such a scholar as Ben Jonson this might seem no more than "small Latine, and lesse Greeke" (to quote

his verses for the First Folio: *see* below).

In *c.* 1577, when Shakespeare was about 13, his father's fortunes began to decline. He became irregular in his contribution to town levies, and had to give a mortgage on his wife's property at Wilmcote as security for a loan from her brother-in-law, Edmund Lambert. Money was raised to pay this off, partly by the sale of a small interest in land at Snitterfield which had come to Mary from her sisters, partly perhaps by that of the Greenhill Street house and other property in Stratford. Lambert, however, refused to surrender the mortgage, and an attempt to recover the Wilmcote property by litigation proved ineffectual. John Shakespeare's difficulties increased. He ceased to attend the meetings of the corporation, and in 1586 was removed from the list of aldermen. In this state of affairs it is not likely that Shakespeare's school life was prolonged. He may have been apprenticed to some local trade.

4. Marriage.—Whatever his circumstances, they did not deter him from marriage. Rowe records the name of Shakespeare's wife as Hathaway, and Joseph Greene succeeded in tracing her to a family of that name dwelling in Shottery, one of the hamlets of Stratford. Her monument (next to her husband's in Stratford church) gives her first name as Anne, and her age as 67 when she died (Aug. 6, 1623). Various small trains of evidence identify her with the daughter Agnes mentioned in the will of a Richard Hathaway of Shottery, who died in 1581, and who was owner of a farmhouse called Hewland, later to be known as "Anne Hathaway's Cottage." (Agnes was legally a distinct name from Anne, but custom treated them as identical.)

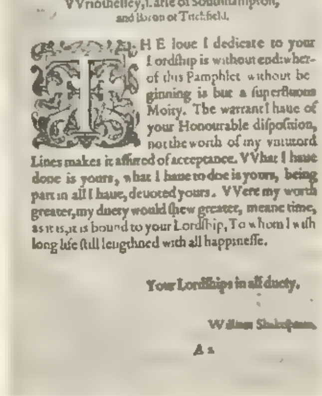
The principal record of the marriage between Anne and Shakespeare is a bond dated Nov. 28, 1582, and executed by Fulk Sandells and John Richardson, two yeomen of Stratford who also figure in Richard Hathaway's will, as a security to the bishop of Worcester for the issue of a licence for the marriage of William Shakespeare and "Anne Hathwey of Stratford," upon the consent of her friends, with only one asking of the banns (*i.e.*, by special licence). The explanation of this form of marriage probably lies in the fact that Anne was already pregnant, and in the nearness of Advent, within which marriages were prohibited, so that the ordinary procedure—by which the banns are called on three successive Sundays—would have entailed a delay until after Christmas. It has been suggested that some form of civil marriage had already taken place, so that a canonical marriage was required only to enable Anne to secure the legacy left her by her father "at the day of her marriage," but there is no evidence of this. On Nov. 27, the day before that on which the bond was executed, an entry was made in the bishop's register of the issue of a licence for a marriage between "Willelmum Shaxpere" and "Annam Whateley de Temple Grafton." However, the bond, as an original document, is the better authority; it is possible that in the register there was a mistake of "Whateley" for "Hathaway." Temple Grafton may have been indicated in the licence as being the place of marriage. There are no contemporary registers for Temple Grafton, and there is no entry of the marriage in those for Stratford. There was apparently a tradition in the 19th century that the marriage had been entered in the registers for Luddington, a chapelry within the parish, but these had already been destroyed when the tradition was recorded.

The Shakespeares' first child, Susanna, was baptized on May 26, 1583; twins, Hamnet and Judith, were baptized on Feb. 2, 1585.

5. The Missing Years.—After this, nothing certain is known of Shakespeare until 1592, when he emerges as an actor and rising playwright in London. There has been much conjecture about what experience helped to fill this gap. One story, first given currency as an addition by Dr. Johnson to his reprint, in 1765, of Rowe's *Life*, says that he "fled to London from the terror of a criminal prosecution," and began his connection with the theatre by holding horses at playhouse doors. A more likely suggestion was put forward by Aubrey, who said that he had heard from an actor who had known Shakespeare, that Shakespeare, in his younger days, had been a schoolmaster in the country. This gains some support from the sort of plays with which Shakespeare began his career as a dramatist: these are strongly academic in style, based closely on Roman comedy, as might be expected of someone who had recently been teaching. The "criminal prosecution" referred to has been connected with an incident mentioned by Rowe, and also by a Richard Davies who became rector of Sapperton, Gloucestershire, in 1695. According to Rowe, Shakespeare was prosecuted for stealing deer from the estates of Sir Thomas Lucy (*q.v.*), and left Stratford to avoid further prosecution; according to Davies, he was whipped and imprisoned by Lucy. Despite discrepancies of detail, likely in a tradition originating in village gossip and handed down orally, there may be a kernel of truth in this story. It seems fairly certain that Shakespeare left Stratford soon after the birth of the twins, and that he went, either immediately or later, to London. It has been suggested—initially by Edmond Malone (*q.v.*), in his valuable life of Shakespeare, that he followed a company of traveling players to London. Later scholars have pointed out that the Earl of Leicester's Men were in Stratford in 1586–87, and that this company may have been taken over on Leicester's death in 1588 by Lord Strange (later earl of Derby), and on Derby's death in 1594 by the lord chamberlain, Henry Carey, 1st Lord Hunsdon, and then by the 2nd Lord Hunsdon, who also became lord chamberlain. In this case, the company, known successively as Strange's Men, Derby's Men, and the Lord Chamberlain's (or Hunsdon's) Men, may have been that with which Shakespeare was connected as player and playwright for the rest of his life. It is not possible, however, to prove a continuity between Leicester's company and Strange's, and, although the names of many of Strange's company in and around 1593 are on record, Shakespeare's is not among them.

6. In London.—What is clear is that by the summer of 1592 he had begun to emerge as a playwright, and had evoked the jealousy of at least one of the group of "school dramatists," or "university wits," who claimed a monopoly of the stage (*see* ENGLISH LITERATURE: *Elizabethan and Jacobean Drama*). This was Robert Greene (*q.v.*), who, in an invective on behalf of the playmakers against the playactors, forming part of *Greenes Groatsworth of Wit* (1592), speaks of "an vpstart Crow, beautified with our feathers, that with his *Tygers hart wrapt in a Players hyde*, supposes he is as well able to bombast out a blanke verse as the best of you: and beeing an absolute *Iohannes fac totum* [*i.e.*, Jack of all trades], is in his owne conceit the onely Shake-scene in a countrey." The play upon Shakespeare's name and the parody of a line from 3 *Henry VI* ("O tiger's heart wrapped in a woman's hide!") make the reference unmistakable.

The London theatres were closed, first through riots and then through plague, from June 1592 to April 1594, except for about a month at each Christmas, and the companies were dissolved or driven to the provinces. Even if Shakespeare had been connected with Strange's Men during their London seasons of 1592 and 1593, it does not seem that he traveled with them. *Venus and Adonis* was published in April 1593, and *Lucrece* in May 1594. Both poems were printed by Shakespeare's schoolfellow, Richard Field, who had gone to London from Stratford as a printer's apprentice in 1579. Each has a dedication to Henry Wriothesley, earl of Southampton (*q.v.*), a brilliant and accomplished court favourite, not yet of age. A possibly supersubtle criticism discerns an increased warmth in the tone of the second dedication, and this is supposed to argue a marked growth of intimacy. The fact of an intimacy between Southampton and Shakespeare is vouched for by the story handed down from Sir William Davenant (*q.v.*) to Rowe that Southampton gave Shakespeare £1,000 "to enable him to go through with a purchase which he heard he had a mind to." The date of this generosity is not specified, and there is no known



TO THE RIGHT
HONOVRABLE, HENRY
VVriothesley, Earle of Southhampton,
and Baron of Titchfield.

THE loue I dedicate to your Lordship is without end: wherof this Pamphlet without beginning is but a superfluous Moity. The warrant I haue of your Honourable disposition, not the worth of my vntutord Lines makes it assured of acceptance. VVhat I haue done is yours, what I haue to doe is yours, being part in all I haue, deuoted yours. VVere my worth greater, my duety would shew greater, meane time, as it is, it is bound to your Lordship, To whom I wish long life still lengthned with all happinesse.

Your Lordships in all duety.

William Shakespeare.

A 2

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

DEDICATION OF THE FIRST EDITION OF "LUCRECE," 1594

purchase by Shakespeare which can have cost anything like £1,000.

There is a surmise, supported by ingenious argument, that Shakespeare's enforced leisure enabled him to make of 1593 a *Wanderjahr*, and in particular that the traces of a visit to northern Italy may be seen in the local colouring of *Lucrece* as compared with that of *Venus and Adonis*, and in that of the group of plays which may be dated in or about 1594 and 1595 as compared with those that preceded it (see *Chronology of the Plays*, below). It must, however, be kept in mind that, while Shakespeare may perfectly well, at this time or earlier, have traveled to Italy, and possibly to Denmark and even Germany as well, there is no direct evidence of this, and that inference from internal evidence is a dangerous guide when a writer of so assimilative a temperament as Shakespeare is concerned.

From the reopening of the theatres in the summer of 1594 Shakespeare's status is in many ways clearer. He had certainly become a leading member of the Lord Chamberlain's company by December, when his name appears for the first and only time in the accounts of the treasurer of the chamber as one of the recipients of payment for their performances at court; there is every reason to suppose that he continued to act with and write for the same associates to the close of his career.

The history of the company may be briefly told. At the death of the lord chamberlain on July 22, 1596, it passed under the protection of George, 2nd Lord Hunsdon, and again became the Lord Chamberlain's Men when he was appointed to that office on March 17, 1597. On his accession James I took this company under his patronage, and during the rest of Shakespeare's connection with the stage they were the King's Men. The records of performances at court show that they were by far the most favoured of the theatrical companies, their nearest rivals being the company known during the reign of Elizabeth I as the Admiral's Men, and then as Prince Henry's. From the summer of 1594 to March 1603 they seem to have played almost continuously in London, although they undertook a provincial tour during autumn 1597, when the London theatres were closed because of the interference of some of the players in politics. They traveled again during 1603 when the plague was in London, and during parts of the summers or autumns of most years thereafter. In 1594 they were playing at a theatre at Newington Butts (then a village not far south of London Bridge), and probably afterward at the Cross Keys Inn in the City. It is natural to suppose that in later years they used the Theatre in Shoreditch (the first public playhouse in London: *see* THEATRES [STRUCTURES]), since this was the property of the father of their principal actor, Richard Burbage (*q.v.*). The Theatre was pulled down in 1598; after a short interval, during which the company may have played at the Curtain (also in Shoreditch), Richard Burbage and his brother Cuthbert rehoused it in the Globe on Bankside, Southwark, built partly out of the materials of the Theatre. There the profits were divided between the members of the company as such and the owners of the building ("housekeepers"); shares in the "house" were held by Shakespeare and some of his leading "fellows." About 1608 another playhouse became available for the company in the "private" (or winter) house of the Blackfriars. This was also the property of the Burbages. A somewhat similar arrangement was made with profits.

Shakespeare is reported by Aubrey to have been a good actor, although, according to one account, he never rose above such a comparatively minor, though impressive, part as that of the Ghost in *Hamlet*, or Adam in *As You Like It*. As a dramatist, however, he was the mainstay of the company for at least 15 years, during which Jonson, Dekker, Beaumont and Fletcher, and Tourneur also wrote for them. On an average he must have written about two plays a year for them, although he seems to have been most productive during the opening years of the period.

7. Prosperity and Fame.—In a worldly sense he flourished, and *c.* 1596, if not earlier, he was able to return to Stratford as a man of substance. There is no evidence to show whether he had visited the town in the interval, or whether he had taken his wife and family to London. His son Hamnet died in 1596. His father's affairs had remained unprosperous. He had incurred debts, partly through becoming surety for his brother Henry's debts, and in 1592 his name was included in a list of recusants at or near Stratford, accused of "not comminge monethlie to the churche," with a note by the commissioners that in his case the cause was believed to be fear of process for debt. William Shakespeare's money must have made a considerable difference. The prosecutions for debt ceased, and in 1597 a new action was brought in chancery for recovery from the Lamberts of the mortgaged Wilmcote property, but apparently without result. Another step was taken to secure the dignity of the family by an application in 1596 to the heralds for the confirmation of a coat of arms said to have been granted to John Shakespeare while he was bailiff. The shield was described in the grant of arms of Oct. 20, 1596, as "Gold upon a bend sables a spear of the first (*i.e.*, gold) steeled argent. And for his crest . . . a falcon, his wings displayed argent, standing on a wreath of his colours; supporting a spar gold, steeled argent, set upon a helmet with mantles and tassels." The motto was *Non sanz droict* ("Not without right"). In 1599 there was a further application, for leave to impale the arms of Arden, in right of Shakespeare's mother; however, no use of the Arden arms by the Shakespeares can be traced. In 1597 Shakespeare made an important purchase for £60 of the house and gardens of New Place in Chapel Street, one of the largest houses in Stratford.

Presumably John Shakespeare ended his days in peace. A visitor to his glover's shop remembered him as "a merry Cheekd old man," always ready to crack a jest with his son. He died in September 1601, and his wife in September 1608, and the Henley Street houses passed to William. Aubrey records that William paid annual visits to Stratford, and there is evidence that he kept in touch with the life of the place. The correspondence of his neighbours, the Quineys (the only contemporary letters to mention Shakespeare), in 1598 contains an application to him for a loan to Richard Quiney on a visit to London, and a discussion of possible investments for him in the neighbourhood of Stratford. In 1602 he rented a copyhold cottage in Chapel Lane, perhaps for his gardener, and in

BY COURTESY OF THE GUILDHALL LIBRARY, LONDON

THE BANKSIDE THEATRES AS THEY APPEARED BETWEEN 1614 AND 1644

This engraving is the most accurate view of the Bankside theatres in Shakespeare's time. However, the engraver accidentally interchanged the names of the theatres, so that the circular building at centre left, labeled "Beere bayting" (bear-baiting); *i.e.*, the Beargarden Theatre, is really the Globe, and vice versa. From *Long View of London* by Wenceslaus Hollar, Amsterdam, 1647

the same year he invested £320 in an estate of 107 ac. in the open fields of Old Stratford, with 20 ac. of pasture and common rights; in 1605 he purchased a lease of certain tithes in Stratford parish, which brought in an income of about £60 a year.

He continued to live in London, near the theatres. There is evidence that in October 1596 he was living in Bishopsgate, and that he later moved to Bankside, perhaps in 1599, when the Globe Theatre on Bankside was opened by the Chamberlain's Men. There is evidence that *c.* 1604 he "lay" (*i.e.*, lodged) in the house of Christopher Mountjoy, a Huguenot tiremaker (maker of head-dresses), at the corner of Silver Street and Monkwell Street in Cripplegate. A note by Aubrey throws light not only on his abode, but on his personality. Like much of Aubrey's information about Shakespeare, it seems to have come from William Beeston, and is as follows: "The more to be admired q[uod] he was not a company keeper, lived in Shoreditch, wouldn't be debauched, & if invited to court; he was in paine." Against this evidence of the correctness of Shakespeare's morals are to be placed an anecdote of a tiring-house amour in 1602, retailed by a Middle Temple student, and a Restoration scandal which made him the father, by the hostess of the Crown Tavern at Oxford, where he stayed en route for Stratford, of Sir William Davenant, who was born in February 1606. His credit at court is implied by Jonson's references to the Sweet Swan of Avon's "flights upon the banks of Thames/That so did take Eliza and our James!"; and by stories of the origin of *The Merry Wives of Windsor* in Elizabeth I's desire to see Falstaff in love, and of a letter (now lost, but thought to have been long preserved by Davenant) written to him by James I. It was noticed by the contemporary playwright, Henry Chettle, however, that his "honied muse" dropped no "sable tear" to celebrate the death of the queen. Southampton's patronage may have introduced him to the brilliant circle around the earl of Essex, but there is no reason to suppose that he or his company was regarded as responsible for the performance of *Richard II* given at the command of some of the followers of Essex as a prelude to the disastrous rising of February 1601. The editors of the first collected edition of his plays (the First Folio, 1623), John Heminge and Henry Condell (*qq.v.*), in their preface to it, speak also of favours received by the author in his lifetime from William Herbert, earl of Pembroke, and his brother Philip Herbert, earl of Montgomery (*see* also *The Poems*, below).

He appears to have been on cordial terms with his fellow-actors and dramatists. An actor in the company, Augustine Phillips, left him a small legacy in 1605, and in his own will he paid a similar compliment to Richard Burbage, and to Heminge and Condell. His relations with Ben Jonson (*q.v.*), whom he is said by Rowe to have introduced to the world as a playwright, have been much discussed. Jests are preserved which, even if apocryphal, indicate a considerable friendship; this is not inconsistent with occasional passages of arms. One of these is referred to in the third of the Parnassus plays (*q.v.*), performed *c.* 1601, in which two actors in the same company as Shakespeare, William Kempe and Richard Burbage, are introduced as characters. Kempe, speaking to Burbage, comments on the style of the university playwrights, who "smell too much of . . . Ovid . . . Why heres our fellow [*i.e.*, fellow-actor] Shakespeare puts them all downe, ay and Ben Jonson too. O that Ben Jonson is a pestilent fellow, he brought up Horace giving the Poets a pill, but our fellow Shakespeare hath given him a purge that made him beray his credit." The reference is to Jonson's *The Poetaster* (performed *c.* 1601), in which Jonson (under the name of Horace) gives John Marston, one of his opponents in the War of the Theatres of 1599–1602, pills to cure him of his windy words. It has been suggested that Shakespeare's "purge" to Jonson may have been the description, in Act I, scene ii, of *Troilus and Cressida* (written 1601–02), of Ajax and his "humours." Jonson, on the other hand, did not spare Shakespeare in either the prologues to his plays or his private conversation. He told William Drummond of Hawthornden, when he visited him in Scotland in 1618, that "Shakesperr wanted Arte"; but the verses he contributed to the First Folio are generous enough to make all amends, and in *Timber: or, Discoveries*, a selection from his notebooks, he praises Shakespeare highly, though, as is to be expected from one who, both as man and dramatist, was as different from Shakespeare as a contemporary could be, deploring in him a facility in writing and a personal levity that he did not share (*see* also *Literary Criticism*, below). The passage is of interest as the considered contemporary judgment of a genius in his own right:

I remember, the Players have often mentioned it as an honour to *Shakespeare* that in his writing . . . hee never blotted out line. My answer hath beene, would he had blotted a thousand . . . I had not told posterity this, but for their ignorance, who choose that circumstance to command their friend by, wherein he most faulted. And to justify mine owne candor, (for I lov'd the man, and doe honour his memory (on this side Idolatry) as much as any.) Hee was (indeed) honest, and of an open, and free nature; had an excellent *Phantsie;* brave notions, and gentle expressions: wherein hee flow'd with that facility, that sometime it was necessary he should be stop'd; . . . His wit was in his owne power; would the rule of it had beene so too . . . But hee redeemed his vices, with his vertues. There was ever more in him to be praysed, than to be pardoned.

In a notebook kept by John Ward (vicar of Stratford 1662–81), there is a reference to a "merry meeting" between Shakespeare, Jonson, and Michael Drayton, at which, presumably from too hard drinking, Shakespeare "contracted" the fever of which he died; and Thomas Fuller (*q.v.*), in his *History of the Worthies of England*, published in 1662, but written considerably earlier, gives a description of the "wit-combates" between Shakespeare and Jonson which, though imaginative rather than actual, is probably based on hearsay about the relationship between them.

Of Shakespeare's literary reputation during his lifetime there is ample evidence. From the time of the publication of *Venus and Adonis* and *Lucrece*, allusions in praise of his work both as poet and dramatist, and often to himself by name, come from writers of every kind and degree. Perhaps the most interesting from the biographical point of view are contained in the *Palladis Tamia* (1598), a kind of literary handbook by Francis Meres (*q.v.*), for Meres not only writes of him as "the most excellent in both kinds [*i.e.*, comedy and tragedy] for the stage," and one of "the most passionate among us to bewaile and bemoane the perplexities of Love," but also lists the 12 plays already written. This list has served as a starting point for all modern attempts at a chronological arrangement of Shakespeare's works. It is, moreover, from Meres that we first hear of "his sugred Sonnets among his private friends." Two sonnets were printed in 1599 in a verse miscellany called *The Passionate Pilgrim*, ascribed on the title page to Shakespeare, but most of Shakespeare's sonnets remained unpublished until 1609 (see *The Poems*, below).

8. Retirement.—In *c.* 1610 Shakespeare seems to have left London, and to have settled at New Place, Stratford. There he lived the life of a retired gentleman, on friendly terms with the richest of his neighbours, the Combes (for whom there is a tradition that he wrote satirical epitaphs), and interested in any local affairs, such as a bill for the improvement of the highways in 1611 and a proposed enclosure of the open fields at Welcombe in 1614, that might affect his income or his comfort. He had a garden with a mulberry tree (if we are to believe Sir Hugh Clopton, the last of the family who owned the house from 1677 to 1751; and according to whom the mulberry tree in its garden had been planted by Shakespeare in *c.* 1609; it was cut down in 1758). Shakespeare's brothers Gilbert and Richard were both still living in Stratford. His sister Joan had married William Hart, a hatter; they had three sons, and in 1616 were living in one of Shakespeare's two houses in Henley Street. In 1607 his elder daughter, Susanna, had married John Hall (1575–1635), a physician of some reputation. They lived in Stratford and had one child, Elizabeth, born in 1608. His younger daughter, Judith, married Thomas Quiney, a vintner, a member of the family who were the Shakespeares' neighbours in Henley Street.

His retirement did not imply an absolute break with London life. In 1613 he devised an *impresa* (or emblem), to be painted by Richard Burbage, and worn by the earl of Rutland in the annual tournament held on Accession Day. In the same year he purchased for £140 a freehold house in Blackfriars—once the gate-house to the lodging of the prior of Blackfriars—and immediately mortgaged it for £60. Both the conveyance (March 10) and the

mortgage (March 11) bear Shakespeare's signature (his only other certain extant signatures being one to a deposition in the Belott-Mountjoy lawsuit, in which he was involved in 1612, and the three on his will). He was probably in London at this time (March 1613) after the festivities for the wedding of Princess Elizabeth to the Elector Palatine, when his company gave about 20 performances, of which 8 were of plays by Shakespeare. He may have stayed on for the production of *Henry VIII* at the Globe in June; there is a tradition that he instructed the actor who played the part of the king. But at the performance on June 29, 1613, the thatched roof of the theatre caught fire from the discharge of one of the guns firing the royal salute in Act I, sc. iv, and the theatre was destroyed. Although it was rebuilt in 1614 (with a tiled roof and in a more elaborate style), the fire is generally taken as being the date of the ending of Shakespeare's theatrical career. His last years were spent in Stratford, perhaps, as Rowe says, "in ease, retirement, and the conversation of friends."

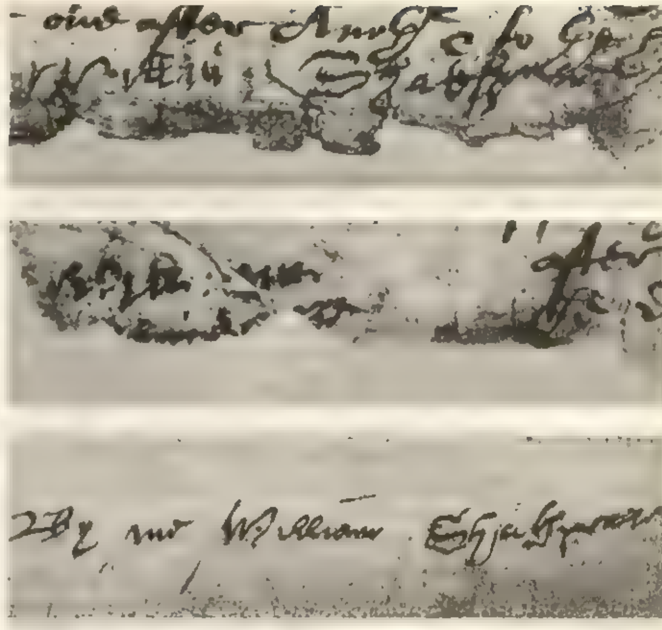
9. Will and Death.—Shakespeare made his will on March 25, 1616, apparently in some haste, as the executed deed is a draft with many erasures and interlineations. It was found in 1747 by Joseph Greene, and is preserved in Somerset House, London. There were legacies to his daughter Judith, his sister Joan, and his granddaughter Elizabeth, and remembrances to friends in Warwickshire and London; but the bulk of the property was left to his daughter Susanna under a strict entail which points to a desire to found a family. Shakespeare's wife, who had, of course, dower in most of the property, is mentioned only in an interlineation, by which the "second best bed with the furniture" was bequeathed to her. Much nonsense has been written about this, but it seems quite natural. The best bed was an important chattel, which would go with the house, in which Anne, as the widow, had the right to live with her daughter. The estate was not a large one: Aubrey's estimate of its value as £200 or £300 a year sounds reasonable. The sum total of Shakespeare's known investments amounts to £960. Sir Sidney Lee's calculation that his theatrical income must have reached £600 a year is a considerable overestimate; it can hardly have been more than about £200. Shakespeare's financial interest in the Globe and Blackfriars probably ended on or before his death.

A month after his will was signed, Shakespeare died, on April 23 (Old Style; May 3, New Style), 1616. As a tithe owner, he was buried in the chancel of the parish church. The doggerel verses on the gravestone in the chancel that local tradition has assigned to his own pen are as follows:

> Good frend for Iesvs sake forbeare,
> To digg the dvst encloased heare!
> Blest be ye man yt spares thes stones,
> And curst be he yt moves my bones.

A more elaborate monument with a bust was set up on the chancel wall (see *Portraits of Shakespeare,* below). Anne Shakespeare followed her husband on Aug. 6, 1623, and was buried next to him. The family was never founded. Shakespeare's granddaughter, Elizabeth, who inherited the entailed property, made two childless marriages, the first in 1626 with Thomas Nash of Stratford, who died in 1647, the second in 1649 with John Bernard of Abington Manor, Northamptonshire, who was knighted in 1661, and died in 1674. Judith Quiney had three sons, all of whom had died unmarried by 1639. There were, therefore, no direct descendants of Shakespeare living after Lady Bernard's death in 1670. Those of his sister, Joan Hart, can, however, still be traced: the 11th descendant of Shakespeare's sister, H. G. Shakespeare Hart (1898–), had a daughter in 1940.

On Lady Bernard's death the Henley Street houses passed to the Harts, in whose family they remained until 1806, when they were sold. In 1847 they were bought by the Birthplace Committees of Stratford and London; in 1857 the Birthplace was restored, and in 1891 it was vested, with New Place (bought by public subscription in 1862), in the Trustees and Guardians of Shakespeare's Birthplace. In 1892 the Trustees bought Anne Hathaway's Cottage; in 1930, Mary Arden's house at Wilmcote; and in 1949, Hall's Croft, the home of Shakespeare's son-in-law. Lady Bernard had disposed of the Blackfriars house. The rest of the property



BY COURTESY OF THE PUBLIC RECORDS OFFICE

ENLARGEMENTS OF THE THREE SIGNATURES FROM SHAKESPEARE'S WILL, DATED MARCH 25, 1616

was sold after her husband's death under the terms of her will, and New Place passed, first to the Cloptons (who had originally built it in *c.* 1490), who rebuilt it, and then to the Rev. Francis Gastrell, who pulled it down in 1759. The site was laid out as a public garden in 1872.

The Shakespeare Memorial Theatre, on the bank of the River Avon, was opened in 1879; a season of performances of Shakespeare's plays is given there every year. The original theatre was destroyed by fire in 1926; the new theatre was opened on April 23, 1932. The money (half of it from the United States) had been raised by public subscription.

10. Appearance, Personality, and Opinions.—Numerous attempts have been made to deduce from the plays, and from the information available, some impression of Shakespeare's personal appearance, character and personality, and opinions. None of the portraits is sufficiently well-authenticated to provide a reliable guide to his appearance (see *Portraits of Shakespeare,* below). Aubrey asserts that he was "a handsome well shap't man: very good companie and of a very readie and pleasant smooth witt," and this is probably based on hearsay, and is sufficiently moderate and particular to be acceptable as truth, not conventional praise. The lameness attributed to him by some writers has its origin in a literal interpretation of references to spiritual disabilities in the *Sonnets* (37 and 89).

There has been much conjecture about Shakespeare's religious views. The Richard Davies, from whom the least likely of the stories of Shakespeare's deer stealing derives (*see* above), is the only early authority for the idea that Shakespeare "dyed a papist," and later biographers have not generally accepted this, although some critics have claimed to find indirect evidence of a change of religious allegiance in the late plays, especially *The Tempest.* The suggestion has been made that Shakespeare's father was, or became, a Catholic. This is based partly on the alleged discovery in the mid-18th century of a "spiritual testament," or will, professing the Catholic faith, and said to have been written by John Shakespeare. Malone published it in his 1790 edition of Shakespeare's works, but later declared that he had evidence (not stated) that it could not have been connected with the Shakespeare family. It has also been suggested that the will was a forgery. The only other evidence of Shakespeare's own religious convictions—apart from that to be derived from the plays—is a record in the accounts of the Stratford corporation that in 1614 "twenty pence" was paid for sack and claret for the entertainment of a visiting preacher at New Place.

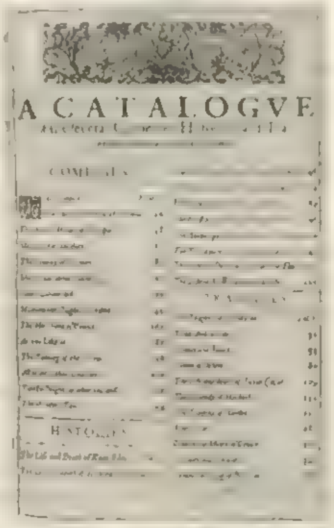
II. THE PLAYS

A. The First Folio and the Quartos

The first collected edition of Shakespeare's plays was printed at the press of William Jaggard (*q.v.*), and issued by a group of booksellers in 1623. This is known as the First Folio (F1): its title page title is *Mr. William Shakespeares Comedies, Histories, & Tragedies.* It has dedications to the earls of Pembroke and Montgomery, and to "the great Variety of Readers," both dedications signed by two of Shakespeare's "fellows" at the Globe, John Heminge and Henry Condell; and commendatory verses by Ben Jonson, Hugh Holland, Leonard Digges, and an unidentified "I. M." The Droeshout engraving (see *Portraits of Shakespeare*, below) forms part of the title page. Except for *Pericles* (*see* below), all the plays ordinarily printed in modern editions of Shakespeare's works are included in the First Folio. Of these 18 were there published for the first time. The other 18 had already appeared in one or more separate editions, known as the Quartos. The following list gives the date of the First Quarto (Q1) of each such play, and also that of any later Quarto which differs materially from it.

Titus Andronicus (1594)
2 *Henry VI* (1594)
3 *Henry VI* (1595)
Richard II (1597, 1608)
Richard III (1597)
Romeo and Juliet (1597, 1599)
Love's Labour's Lost (1598)
1 *Henry IV* (1598)
2 *Henry IV* (1600)
Henry V (1600)
A Midsummer Night's Dream (1600)
The Merchant of Venice (1600)
Much Ado About Nothing (1600)
The Merry Wives of Windsor (1602)
Hamlet (1603, 1604)
King Lear (1608)
Troilus and Cressida (1609)
Othello (1622)

Entries in the register of copyrights kept by the Company of Stationers (the Stationers' Register) indicate that editions of *As You Like It* and *Antony and Cleopatra* were contemplated, but not published, in 1600 and 1608 respectively.



BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

TABLE OF CONTENTS OF THE FIRST FOLIO, 1623

The Quartos vary in quality. Some contain texts practically identical with those of the First Folio; others show variations so material as to suggest that some alteration, generally by way of shortening for stage purposes, took place. A group of First Quartos are generally known as "bad" Quartos, being first so-called in A. W. Pollard's *Shakespeare Folios and Quartos . . . 1594–1685* (1909), in which he pointed out that the reference in Heminge and Condell's preface to the First Folio to "diverse stolne and surreptitious copies, maimed, and deformed by frauds . . . of injurious impostors" applied not to all the Quartos (as had previously been thought), but to those of which the texts are unusually corrupt —2, 3 *Henry VI*, *Romeo and Juliet*, *Henry V*, *Hamlet*, and *The Merry Wives of Windsor*. To these, later textual researches have added *King Lear* and *Richard III;* there was probably also a "bad" Quarto, now lost, of *Love's Labour's Lost.* The problems presented by "bad" Quartos differ from one play to another: all show signs of a textual corruption far greater than is explicable by bad transcription or printing. By comparison with better texts, it is possible to see that some passages have been omitted (so that "bad" Quartos tend to be shorter than First Folio texts), and that others are confused by interpolations of passages from other parts of the same play and even from other plays (including some not by Shakespeare), and by inversion of word and sentence order, by printing prose as verse and verse as prose, and by use of loose synonyms or verbal equivalents for the words intended. It is generally thought that these Quartos have a "surreptitious" origin in having been reconstructed from memory by an actor or actors, or a prompter, in the company. Earlier theories that they represent early versions of the plays have been abandoned, since it was pointed out in 1923 by W. W. Greg and R. C. Rhodes that the smaller parts are less corrupt than the others, and that this suggests "memorial reconstruction" by actors who were accustomed to playing the minor roles (*see* also *Textual Criticism*, below). Most of them must have been printed without the consent of the theatrical companies owning the plays; this is also observed in connection with plays by other authors.

B. Other Plays Attributed to Shakespeare

Shakespeare's name or initials were printed on the title pages of *Locrine* (1595), *Sir John Oldcastle* (1600), *Thomas Lord Cromwell* (1602), *The London Prodigal* (1605), *The Puritan* (1607), *A Yorkshire Tragedy* (1608), and *Pericles* (1609). It is not likely that (except for *Pericles*) he wrote any part of these plays, some of which were not even produced by his company. They were not included in the First Folio, or in a reprint of it, with minor corrections, in 1632 (the Second Folio; F2); but all seven were appended to the second issue (1664) of the Third Folio (F3; 1663), and to the Fourth Folio (F4; 1685). Shakespeare is named as joint author with John Fletcher (*see* below; also Beaumont and Fletcher) on the title page of *The Two Noble Kinsmen* (published 1634) and with William Rowley (*q.v.*) on that of *The Birth of Merlin* (1662); there is no reason for rejecting the former ascription, or for accepting the latter. Late entries in the Stationers' Register assign to him *Cardenio* (registered 1653; with Fletcher), *Henry I* and *Henry II* (1653; with Robert Davenport), *King Stephen*, *Duke Humphrey*, and *Iphis and Ianthe* (all registered in 1660); none of these is extant. Conjecture has attempted to trace his hand in other plays, of which *Arden of Feversham* (1592), *Edward III* (1596), *Mucedorus* (1598), and *The Merry Devil of Edmonton* (1608) are the most important; he may possibly have had a share in *Edward III.*

More interesting than any of these, however, is a play of which the manuscript, in a poor state of preservation, is now in the British Museum, London. Called, on the vellum cover of the manuscript, "The Booke of Sir Thomas Moore," this was first published as *Sir Thomas More* (by which title it is generally known) in 1844, and since 1911, when W. W. Greg published a type facsimile edition of it, it has been the subject of much scholarly research.

The greater part of the manuscript is written in a handwriting identified as that of Anthony Munday (*q.v.*), but to this interpolations of varying lengths have been added, apparently by five other hands. These have been identified as those of Henry Chettle, perhaps Thomas Heywood, Thomas Dekker, a professional scribe whose handwriting is known from another manuscript play, and Shakespeare. The section thought to be in Shakespeare's handwriting consists of three pages (147 lines of blank verse) dealing with More's pacification of the 1517 May Day riots (*see* More, Sir Thomas), and scholars have based their theory that it is by Shakespeare on comparisons of style and political philosophy as well as of orthography and paleography. (*See* also *Textual Criticism*, below.)

An attempt to publish a collected edition of the plays seems to have been made in 1619. It was apparently planned to bring out ten plays—*The Merchant of Venice* and *A Midsummer Night's Dream;* the "bad" Quarto versions of the *Henry VI* plays, the *Merry Wives*, *King Lear*, and *Henry V;* two of the spuriously attributed plays; and *Pericles.* There is a possibility that extant undated Quartos of *Romeo and Juliet* and *Hamlet* were connected with the venture. Official intervention hampered the enterprise, and the first ten plays came, separately, surreptitiously, and, some of them, with false dates and imprints, from the press of William Jaggard; the other two were printed without dates by William Stansby for the owner of the copyright, John Smethwick, later a First Folio shareholder.

C. Chronology of the Plays

The First Folio, unfortunately, does not give the dates at which the plays in it were written or produced; the endeavour to supply

this deficiency has been one of the main preoccupations of Shakespearean scholarship, since Edmond Malone's "An Attempt to Ascertain the Order in Which the Plays of Shakespeare Were Written" (1778). The investigation is not a mere piece of barren antiquarianism, for on it depends the possibility of appreciating the work of the world's greatest dramatic poet, not as if it were an articulated whole like a philosophical system, but in its true aspect as the reflection of a vital and constantly developing personality. A starting point is afforded by the dates of the Quartos and the entries in the Stationers' Register which refer to them, and by the list of plays inserted by Francis Meres in his *Palladis Tamia* (1598). This includes *The Two Gentlemen of Verona, The Comedy of Errors, Love's Labour's Lost, A Midsummer Night's Dream, The Merchant of Venice, Richard II, Richard III, Henry IV, King John, Titus Andronicus,* and *Romeo and Juliet,* as well as a mysterious *Love's Labour's Won,* which may be a play once printed in Quarto and no longer surviving, or an alternative title for one of the other comedies. (In this case, an earlier dating would have to be assigned to whichever one was thought to be represented by this title. *Much Ado, All's Well that Ends Well,* and *Troilus and Cressida* have been suggested.) There is a mass of supplementary evidence, drawn partly from notices in other writings, or in diaries, letters, account books, and similar records; partly from allusions to contemporary persons and events in the plays themselves; partly from parallels of thought and expression between each play and those nearest to it in time; and partly from considerations of style, including the so-called "metrical tests" (or "verse tests") which depend upon a statistical analysis of the metrical structure of Shakespeare's verse, and the development of his feeling for rhythm. The result of any such investigation is certainly not a demonstration, but, in the logical sense, a hypothesis, which serves to colligate the facts and is consistent with itself and with the known events of Shakespeare's external life.

The following list is an attempt to arrange the dates of production of the plays according to the theatrical seasons, from autumn to autumn, in which they may have fallen. It is framed on the assumption that Shakespeare ordinarily wrote two plays a year (as John Ward, vicar of Stratford 1662–81, records in his notebooks); but some slackening of production in the later years seems probable. This chronology is taken from Sir Edmund Chambers' *William Shakespeare* (1930). Neither the order in which the plays are given nor their distribution lays claim to more than approximate accuracy. Later scholarship has tended to push back the dates of the earlier plays, to date 1 *Henry VI* before 2 and 3, and to argue for numerous minor alterations. However, as Chambers' book remains the standard scholarly life of Shakespeare, it is convenient to retain here his order and chronology:

1590–91
(1, 2) 2, 3 *Henry VI*
1591–92
(3) 1 *Henry VI*
1592–93
(4) *Richard III*
(5) *Comedy of Errors*
1593–94
(6) *Titus Andronicus*
(7) *Taming of the Shrew*
1594–95
(8) *Two Gentlemen of Verona*
(9) *Love's Labour's Lost*
(10) *Romeo and Juliet*
1595–96
(11) *Richard II*
(12) *Midsummer Night's Dream*
1596–97
(13) *King John*
(14) *Merchant of Venice*
1597–98
(15, 16) 1, 2 *Henry IV*
1598–99
(17) *Much Ado About Nothing*
(18) *Henry V*
1599–1600
(19) *Julius Caesar*
(20) *As You Like It*
(21) *Twelfth Night*
1600–01
(22) *Hamlet*
(23) *Merry Wives of Windsor*
1601–02
(24) *Troilus and Cressida*
1602–03
(25) *All's Well That Ends Well*
1604–05
(26) *Measure for Measure*
(27) *Othello*
1605–06
(28) *King Lear*
(29) *Macbeth*
1606–07
(30) *Antony and Cleopatra*
1607–08
(31) *Coriolanus*
(32) *Timon of Athens*
1608–09
(33) *Pericles*
1609–10
(34) *Cymbeline*
1610–11
(35) *Winter's Tale*
1611–12
(36) *Tempest*
1612–13
(37) *Henry VIII*
(38) *Two Noble Kinsmen*

D. Composition and Sources

A more detailed account of the individual plays may now be attempted. The figures prefixed correspond to those given in the table above.

1, 2. The First Quarto of the play called in the First Folio *The second part of Henry the Sixt . . .* is entitled *The First part of the Contention betweene the two Famous Houses, Lancaster and Yorke . . .*, and the Third Quarto (1619), consists of *The First part of the Contention . . .*, together with *The true tragedie of Richard Duke of York* (a play first published in 1595); the Third Quarto title is *The whole Contention betweene . . . Lancaster and Yorke.* The relation of *The Contention* with 2, 3 *Henry VI,* and the extent of Shakespeare's responsibility for either or both, have long been subjects of controversy. The opposite extremes of critical opinion are to be found in two theories, one regarding Shakespeare as the sole author of 2, 3 *Henry VI,* and *The Contention* as a shortened and "surreptitious version" of the original plays, the other regarding *The Contention* as written in collaboration by Christopher Marlowe, Robert Greene, and, possibly, George Peele, and 2, 3 *Henry VI* as a revision of *The Contention,* written, also in collaboration, by Marlowe and Shakespeare. A comparison of the two texts leaves it hardly possible to doubt that the differences between them are to be explained by reporting rather than revision; scholarly opinion has tended more and more to regard the plays as coming from the unaided pen of Shakespeare. Greene's parody, in the "Shake-scene" passage of his *Groatsworth of Wit* (*see* above), of a line which occurs both in *The Contention* and in 3 *Henry VI,* while it clearly suggests Shakespeare's connection with the plays, is evidence neither for nor against the participation of other men, and no sufficient criterion exists for distinguishing stylistically between Shakespeare's earliest writing and that of possible collaborators. But the blank verse of 2, 3 *Henry VI* may quite well be an earlier stage of that found more fully developed in *Richard III,* and it is difficult to assign to anyone other than Shakespeare the humour of the Jack Cade scenes. *Henry VI* is not in Meres's list, but its inclusion in the First Folio is an almost certain ground for assigning to Shakespeare some share in the work. There is no record of contemporary performance of either part.

3. It has been argued that such variety and poor quality of style are found in 1 *Henry VI* that it is difficult to regard Shakespeare as its sole author, even at the earliest stage of his development. It is unlikely that the text of the First Folio represents that of its original performance. The scene in the Temple garden, where the plucking of white and red roses foreshadows the beginning of the Wars of the Roses (Act II, sc. 4) which is the one most obviously Shakespeare's, was probably a later addition. Thomas Nashe, in his *Pierce Penilesse His supplication to the Divell* (1592), refers to a play in which Lord Talbot—the leader of the English against the French—appears on the stage, and this must have been 1 *Henry VI;* it is probably also to be identified with the "Harey the vi" recorded in the Diary of Philip Henslowe (*q.v.*) as having been acted on March 3, 1592, by Strange's Men, probably at the Rose Theatre, a playhouse on Bankside built by Henslowe in 1587–88.

For all three parts of *Henry VI,* based on incidents before and during the Wars of the Roses, the chief historical sources are the *Chronicles* of Edward Hall, Raphael Holinshed, and Robert Fabyan (*qq.v.*).

4. The *Henry VI* series leads directly as historical narrative to *Richard III,* and this, together with its style as compared with that of the plays of 1594–96, suggests the short winter season of 1592–93 as the most likely time for the production of *Richard III.* It is not included in Henslowe's list of the plays acted by Strange's Men during that season, but it may well have been produced by the only other company to appear at court during the Christmas festivities, Lord Pembroke's. The fact that Shakespeare wrote a play, or more than one play, for Strange's Men during 1592–94 does not prove that he never wrote for any other company during the same period; and indeed there is room for guesswork as to the relations between Strange's and Pembroke's Men. The latter are not known to have existed before late 1592, and many difficulties would be solved by the assumption that they originated out of a

division of Strange's, who had amalgamated with the Admiral's, and may have found their numbers too much inflated to enable them to undertake as a whole the autumn tour of that year. If this is so, Pembroke's probably took over the *Henry VI* series of plays (since the part of *The Contention* entitled *The true tragedie of Richard Duke of York* was published as having been performed by them), and completed it with *Richard III* at Christmas. It will be necessary to return to this theory in connection with the discussion of *Titus Andronicus* and *The Taming of the Shrew*. For *Richard III*, as for most of the later historical plays, the second edition (1587) of Holinshed's *Chronicle* is the chief source.

5. To the winter of 1592–93 may also be assigned with fair probability Shakespeare's first experimental comedy, *The Comedy of Errors*. The play contains a reference to the wars of succession in France that would fit any date between 1589 and 1594. The plot is taken from the *Menaechmi*, and to a smaller extent, from the *Amphitruo*, of Plautus (*q.v.*). The *Menaechmi*, translated into English by William Warner, was published in 1595, but there is no known contemporary translation of the *Amphitruo*. A performance of *The Comedy of Errors* by "a company of base and common fellows" (including Shakespeare?) is recorded in the *Gesta Grayorum* (the records of Gray's Inn) as having taken place in Gray's Inn Hall on Dec. 28, 1594.

6. Many scholars have been unwilling to see the hand of Shakespeare in *Titus Andronicus;* the double testimony of its inclusion in Meres's list and in the First Folio makes its total rejection hazardous. A stage tradition was recorded by Edward Ravenscroft, a Restoration dramatist who adapted the play in 1678 (published 1687), that Shakespeare did no more than give a few "master touches" to the work of a "private author." However, abandonment of what are known as "disintegrationist" theories (*i.e.*, theories that any material in Shakespeare's plays markedly inferior to what may be accepted as the normal high standard must be by other dramatists; see *Textual Criticism*, below) has led to greater willingness to accept the play as wholly Shakespeare's. It still remains difficult to produce a convincing and coherent hypothesis about its early stage history. The play was entered in the Stationers' Register on Feb. 6, 1594, and was published in the same year with a title page setting out that it had been acted by the companies of Lords Derby (*i.e.*, Strange, who had succeeded to his father's title on Sept. 25, 1593), Pembroke, and Sussex. It is natural to take this list as indicating the order in which the three companies were concerned with it. Henslowe records the production by Sussex' company of *Titus Andronicus* as a new play on Jan. 23, 1594, only a few days before the theatres were closed by plague, but for the purposes of Henslowe's financial arrangements with the company a rewritten play may have been classed as new. Two years earlier he had also described as new a play called *Tittus and Vespacia* (the title used in Henslowe's Diary; more generally called *Titus and Vespasian*), produced by Strange's Men on April 11, 1592, and although this title suggests a piece about the emperors Titus and Vespasian, there are grounds for supposing this play to have been an early version of *Titus Andronicus*. It is difficult to explain the company names on the title page unless there had been some version earlier than that of 1594. Pembroke's Men are known to have been ruined by August 1593, and it is to be suspected that Sussex' Men, who first appeared in London at Christmas 1593, acquired their stock of plays, and transferred these to the Chamberlain's Men when the companies were reconstituted in the summer of 1594. The Chamberlain's Men were apparently playing *Andronicus* in June. The stock of Pembroke's Men probably included, as well as *Titus and Vespasian*, *Henry VI* and *Richard III*, which also thus passed to the Chamberlain's Men.

The source of the plot is unknown; there are only slight hints for it in Byzantine chronicles. The relationship between the play and a chapbook version of the story, extant only in an 18th-century printing, remains obscure. It is possible that the chapbook represents Shakespeare's source material.

7. An anonymous play called *The Taming of a Shrew*, which can be traced back as far as 1589, was published in 1594 as having been acted by Pembroke's Men. In June 1594 it was being acted by the Chamberlain's. There is little agreement concerning the relationship between *A Shrew* and Shakespeare's *The Shrew*. There are considerable differences between the texts. One theory is that Shakespeare's *The Shrew* is his adaptation of *A Shrew;* another is that *A Shrew* is a "bad" Quarto of *The Shrew* (it shows all the signs of being a "bad" Quarto of something); supporters of the latter view are forced to date Shakespeare's *The Shrew* extremely early. The origins of the play, which is a farce rather than a comedy, are to be found ultimately in widely distributed folktales, and more immediately in the translation (as *Supposes*, 1566?) by George Gascoigne (*q.v.*) of Ludovico Ariosto's *I Suppositi*. Those who regard *The Shrew* as an adaptation of *A Shrew* suggest that it may have been Shakespeare's first task for the newly established Chamberlain's company of 1594 to refurbish the old farce.

8. No very definite evidence exists for the date of *The Two Gentlemen of Verona*, other than the mention of it by Meres in 1598. It is evidently a more rudimentary essay in the genre of romantic comedy than *The Merchant of Venice*, with which it has affinities in its Italian colouring and in the theme of the interrelations of love and friendship; and it may be roughly assigned to the winter of 1594–95. The plot is drawn from various examples of contemporary fiction, especially from the story of the shepherdess Filismena in the Spanish pastoral romance *Diana* (1559?) by Jorge Montemayor (*q.v.*). A play of *Felix and Philiomena* (also based on *Diana*) had already been given at court in 1585, and Shakespeare may have used it.

9. *Love's Labour's Lost*—the first of the plays to be published with his name on the title page—used to be regarded as the first of Shakespeare's plays, and has sometimes been placed as early as 1589. So early a date is improbable. The characters are evidently suggested by Henry of Navarre (later Henry IV of France) and his supporters, the ducs de Biron, de Longueville, and d'Aumont; the last has probably been confused with Charles, duc de Mayenne, to produce the unhistorical character "Dumain." These names would have been familiar to Shakespeare at any time after *c.* 1589, but events from earlier Navarrese history have also been drawn upon, and the channel of transmission of these to Shakespeare is unknown. The absence of the play from the lists in Henslowe's Diary makes it unlikely, though not impossible, that it preceded the formation of the Chamberlain's company; and its lyric character perhaps justifies its being grouped with the other lyric plays of 1594–96. No entry of the play is found in the Stationers' Register; it is most likely that the First Quarto of 1598 replaces a lost "bad" Quarto. The title page describes the play as "corrected and augmented," and as given at Christmas 1597. It was revived for that of 1605.

10. *Romeo and Juliet*, published in 1597 as "often (with great applause)" played by Lord Hunsdon's Men, was probably produced somewhat before *A Midsummer Night's Dream*, as its incidents seem to have suggested the Pyramus and Thisbe parody in the latter play. The text of the First Quarto is "surreptitious," and was "corrected, augmented and amended" in the Second Quarto of 1599. There had been an earlier play on the subject, but the immediate source was *The Tragicall Historye of Romeus and Juliet* (1562) by Arthur Broke (*q.v.*).

11. *Richard II* can be dated with some accuracy by a comparison of two editions of Samuel Daniel's narrative poem *The Civile Warres Between the Two Houses of Lancaster and Yorke*, both dated 1595 and therefore issued between March 25, 1595, and March 24, 1596 (N.S.); the second edition, but not the first contains some close parallels to the play. It is possible that the play was performed on Dec. 9, 1595, at Sir Robert Cecil's house. From the first three Quartos, one in 1597 and two in 1598, the scene of Richard's deposition was omitted, although it was clearly part of the original structure of the play, and its removal leaves an obvious mutilation in the text. There is reason to suppose that this was due to a popular tendency to draw seditious parallels between Richard and Elizabeth I, and it became one of the charges against the earl of Essex and his fellow conspirators in the abortive outbreak of February 1601 that they had produced a performance of a play on Richard's fate to stimulate their followers on the eve of the rising. As the actors of this play were the Lord Chamberlain's Men, it was almost certainly Shakespeare's. The deposition scene

was not printed until after Elizabeth's death, in the Third Quarto of 1608.

12. *A Midsummer Night's Dream*, with its masquelike fairy scenes and the epithalamium at its close, has all the air of having been written for some courtly wedding, and the compliment paid by Oberon to the "fair vestal throned by the west" makes it possible that it was a wedding at which the queen was present. Many occasions have been suggested. The wedding of Mary, countess of Southampton, and Sir Thomas Heneage on May 2, 1594, would fit the setting of the plot; but a widowed countess hardly answers to the "little western flower" of the allegory, and there are allusions in the play to later events and in particular to the rainy weather of 1594–95. The wedding of William Stanley, earl of Derby, brother of the Lord Strange for whose players Shakespeare had written, and Elizabeth Vere, daughter of the earl of Oxford, at Greenwich on Jan. 26, 1595, would meet the conditions, but that of Thomas Berkeley and Elizabeth Carey, granddaughter of the company's patron, Lord Hunsdon, on Feb. 19, 1596, is at least as likely. There appears to be no special source for the play beyond Chaucer's *Knight's Tale* and European fairy lore.

13. *King John* has no very clear indications of date, but stylistically 1596 seems likely, in spite of the improbability of a play on an independent subject drawn from English history's being interpolated in the middle of the Lancastrian series. It would seem that Shakespeare had before him an anonymous earlier play called *The Troublesome Raigne of John King of England*. This was published in 1591, and again, with "W. Sh." on the title page, in 1611. For copyright purposes *King John* appears to have been regarded as a revision of *The Troublesome Raigne*, and in fact the succession of incidents in the two plays is much the same. Shakespeare's dialogue, however, owes little or nothing to that of his predecessor. There is no record of performance before a revival in 1737, and, perhaps because it was regarded as a revision rather than a new play, it was not entered on the Stationers' Register. It was first published in the First Folio.

14. *The Merchant of Venice* is certainly earlier than July 22, 1598, when it was entered in the Stationers' Register. It may have been inspired by the poison plots against the queen and Don Antonio of Portugal by Roderigo Lopez, Elizabeth I's Jewish physician, who was executed in 1594. It shows considerable advance in comic and melodramatic power over earlier plays, and is assigned by most scholars to *c.* 1596. The various stories of which its plot is compounded are based upon themes common to folklore and Italian *novelle*. It has been suggested that Shakespeare had before him a lost play, *The Jew*, of which there are traces as early as 1579, and in which stories illustrating "the greedinesse of worldly chusers" and the "bloody mindes of usurers" seem to have been already combined. *The Jew of Malta* (performed *c.* 1589) by Christopher Marlowe (*q.v.*) may also have contributed something.

15, 16. The first part of *Henry IV* was published in 1598; the entry in the Stationers' Register (Feb. 25) included in the title and description a reference to "the humorous conceits of Sir John Falstaff." The second part was not published until 1600, but it is clear that both parts must have been written by 1598, because, although in Part 1 as published, Shakespeare had already changed the name of the comic character Sir John Falstaff—who in earlier versions had been called Sir John Oldcastle (*q.v.*), after the famous Lollard leader and martyr—in Part 2 there are indications that when it was written, he was still using the name Oldcastle. Thus, in the First Quarto of Part 2 (registered Aug. 23, 1600) the speech-prefix "Oldcastle" is found against Falstaff's speeches; in the epilogue there is the phrase "for Oldcastle died a martyr"; and in Act III, sc. 2, Falstaff is described as having been "page to Thomas Mowbray," which was true of Oldcastle, but not of Sir John Fastolf (*q.v.*), Falstaff's eventual prototype, who had already been represented as a coward in *Henry VI*.

The fact that Shakespeare substituted Fastolf for Oldcastle, with the consequent change of name, and the reasons for it, are referred to in an *Epistle*, written in 1625, by the scholar and librarian Richard James, who explains it as the result of complaints by Oldcastle's descendants at having their ancestor represented as a comic and cowardly buffoon. Nicholas Rowe ascribes the substitution to the queen's intervention. There is also an allusion to the wrong done to Oldcastle in the epilogue to *2 Henry VI*. Presumably Fastolf had no descendants alive in 1598 to protect his reputation.

Shakespeare's source for Oldcastle, and for other details, was probably the anonymous play called *The Famous Victories of Henry V*, registered in 1594 and extant in an edition of 1598, but written much earlier, as there is a record of performance by the Queen's Men in, or before, 1588.

17. A note in the Stationers' Register during August 1600 shows that *Much Ado About Nothing* was already in existence, although its publication was directed to be "stayed." It may plausibly be regarded as the earliest play not included in Meres's list (1598). In 1613 it was revived before James I with the title of *Benedick and Beatrice* (the names of the hero and heroine). The character of the comic constable, Dogberry, is said by Aubrey to have been taken from a constable at Grendon in Buckinghamshire, on Shakespeare's road from London to Stratford. There is no very definite literary source for the play, although some of its incidents are to be found in Ariosto's *Orlando Furioso* and Matteo Bandello's *novelle*.

18. The completion of the Lancastrian series of histories with *Henry V* can be placed in *c.* 1599, since there is an allusion in one of the choruses to the military operations in Ireland in that year of the earl of Essex. The First Quarto (which, although this play was "stayed" at the same time as *Much Ado*, was published in 1600) is a "surreptitious" text, and does not include the choruses. The authentic text was first published in the First Folio.

19. That *Julius Caesar* also belongs to 1599 is shown by an allusion to it in John Weever's *The Mirror of Martyrs: or, the Life and Death of Sir John Oldcastle*, a work written two years before publication in 1601; and by a reference to its performance at the Globe on Sept. 21, 1599, by Thomas Platter of Basel in his account of a visit to London. It was the first of Shakespeare's Roman plays, and, like those that followed, was based on Sir Thomas North's translation (published 1579) of the lives of Brutus, Caesar, and Mark Antony, by Plutarch (*q.v.*).

20. *As You Like It* was one of the plays "stayed" from publication in 1600, and cannot therefore be later than that year. Some trifling evidence suggests that it is not earlier than 1599. The plot is based on *Rosalynde* (1590), a prose romance by Thomas Lodge (*q.v.*), and this in turn was based in part on the pseudo-Chaucerian *Tale of Gamelyn* (*c.* 1350; *see* ROMANCE).

21. *Twelfth Night* may be dated *c.* 1600–01. It quotes part of a song included in Robert Jones's *First Booke of Songes & Ayres* . . . (1600); has been suggested as having been the court entertainment provided on Jan. 6, 1601, before the queen and Virginio Orsini, duke of Bracciano; and is mentioned in the diary of the barrister John Manningham as having been performed at a feast at Middle Temple Hall on Feb. 2, 1602. The principal source of the plot was the "History of Apolonius and Silla," in *Riche His Farewell to Militarie Profession* (1581), by Barnabe Rich (*q.v.*).

22. A play of *Hamlet* (known to scholars as the *Ur-Hamlet*) was performed, probably by the Chamberlain's Men, for Henslowe at Newington Butts on June 11, 1594. There are references to it as a revenge play, and it seems to have been in existence in some form as early as 1589. It was doubtless on the basis of this that Shakespeare constructed his tragedy. There is an allusion in his *Hamlet* to the rivalry between the ordinary stage and the private plays given by boy actors which points to a date after the revival of the acting of plays by the Children of Paul's, a company of boy actors from St. Paul's Choir School who performed both at court and at the cathedral, probably in 1599, and the play is mentioned in a manuscript note by Gabriel Harvey, probably written before the death of Essex in 1601. The play was entered in the Stationers' Register on July 26, 1602. The First Quarto was printed in 1603 and the Second in 1604. The differences of these texts from each other and from that of the First Folio constitute one of the more difficult Shakespearean problems. The First Quarto is certainly "surreptitious." Its title page records performances at the universities of Oxford and Cambridge and elsewhere, as well as in London.

The source of the plot is to be found in legends preserved in the *Gesta Danorum* of Saxo Grammaticus (*q.v.*) and transmitted to Shakespeare or the author of the *Ur-Hamlet* (perhaps Thomas Kyd, *q.v.*) through the version of a novella by Matteo Bandello, in vol. v of François de Belleforest's *Histoires tragiques* (1570). (*See* also HAMLET.)

23. It is reported by John Dennis, in the preface to *The Comical Gallant: or the Amours of Sir John Falstaffe* (1702), his adaptation of Shakespeare's play, that *The Merry Wives of Windsor* was written at the request of Elizabeth I, who wished to see Falstaff in love; and that it was finished by Shakespeare within a fortnight. A date at the end of 1599 or the beginning of 1600, shortly after the completion of the historical Falstaff plays, would seem to be the most natural for this enterprise, and the stylistic evidence agrees with such a date. The play was entered in the Stationers' Register on Jan. 18, 1602. The First Quarto of the same year gives a "surreptitious" text, which was replaced by that of the First Folio. The Windsor setting makes it possible that *The Merry Wives* was produced in the castle there, perhaps with the Children of Windsor Chapel in the fairy parts. The plot has analogies in incidents in Italian *novelle* and in English adaptations of them.

24. Few of the plays present as many difficulties as *Troilus and Cressida*. A play of this name, "as yt is acted by my Lord Chamberlens Men," was entered in the Stationers' Register on Feb. 7, 1603, with a note that "sufficient authority" must be got by the publisher, James Roberts, before he printed it. This can hardly be any other than Shakespeare's play, but it must have been "stayed," for the First Quarto did not appear until 1609, when, on Jan. 28, a new entry for it was made in the Register by another publisher. The text of the Quarto differs from that of the Folio, but not to a greater extent than use of two different copies of the original manuscript might explain. Two alternative title pages are found in copies of the Quarto. On the earlier is a statement that the play was printed "as it was acted by the Kings Maiesties seruants at the Globe"; from the other these words are omitted, and a preface is appended which hints that the "grand possessors" of the play had made difficulties about its publication, and describes it as "never staled with the Stage."

Attempts have been made, mainly on stylistic grounds, to find another hand than Shakespeare's in the prologue and the closing scenes, and even to assign widely different dates to different parts of what is ascribed to Shakespeare. But the evidence does not really bear out these theories, and the style of the whole can be regarded as consistent with a date in 1602. It has been thought that the description of Ajax and his "humours" in Act I, sc. 2, is Shakespeare's "purge" to Jonson in reply to the *Poetaster* (performed *c.* 1601), alluded to in the Parnassus play acted at Cambridge, probably at Christmas 1601–02 (see *Life: Prosperity and Fame*, above). It is tempting to conjecture that *Troilus and Cressida* may have been played, like *Hamlet*, by the Chamberlain's Men at Cambridge, but never taken to London, and in this sense "never staled with the Stage." The only difficulty of a date in 1601 is that a parody of a play on the story of Troilus and Cressida is introduced into an anonymous play called *Histrio-Mastix. Or, the Player Whipt*, written *c.* 1599, but not printed until 1610, in which Troilus "shakes his furious Speare": it has been suggested that this is a punning reference to Shakespeare, and that his *Troilus and Cressida* must therefore have been written before 1599. But Henslowe had produced another play with the same title by Thomas Dekker and Henry Chettle, in 1599, and possibly, therefore, no allusion to Shakespeare is intended.

The material for *Troilus and Cressida* was taken from Chaucer's *Troilus and Criseyde* (*see* also ROMANCE: *Romans d'antiquité*), William Caxton's *Recuyell of the Histories of Troye* (1475), and George Chapman's translation of Homer.

25. Stylistic arguments have led to the dating of *All's Well That Ends Well* in 1602–03 although it has been urged as in the case of *Troilus and Cressida* (and with as little justification) that parts of the play are of a considerably earlier date. The story is derived from one of the tales in Giovanni Boccaccio's *Decameron*, as translated by William Painter in his collection called *The Palace of Pleasure . . .* (1566).

26. A list of plays in the account book of the Revels Office (the office responsible for supervision and payment of special entertainments at court) records that *Measure for Measure* was performed at court on Dec. 26, 1604. It was registered on Nov. 8, 1623, and first published in the First Folio. The fact that the Folio text is not altogether satisfactory has led to theories that the play is a reworking by Shakespeare of an earlier text, and that the two versions of the play (that performed at court in 1604, and that performed later on the public stage) may have differed considerably. It is further suggested that the text finally published in the First Folio contains some passages not by Shakespeare, and that it is, in any case, incomplete.

The plot is taken from a story already used by George Whetstone (*q.v.*) who borrowed it from Giambattista Giraldi Cinthio's *Hecatommithi* (1565).

27. A performance of *Othello* at court on Nov. 1, 1604, is noted in the same list as that recording *Measure for Measure*, and the play may be reasonably assigned to the same year. The play was revived in 1610, when it was seen by the prince of Württemberg at the Globe on April 30. It was entered in the Stationers' Register on Oct. 6, 1621, and a First Quarto was published in 1622. The text of this is less satisfactory than that of the First Folio; it omits a good many lines found in the Folio and almost certainly belonging to the play as originally written. It also contains profane expressions, modified in the Folio, and this points to a date for the original production earlier than the Act to Restrain Abuses of Players of May 1606, which made it an offense to swear oaths on the stage. The plot, like that of *Measure for Measure*, comes from the *Hecatommithi*.

28. The entry of *King Lear* in the Stationers' Register on Nov. 26, 1607, records its performance at court on Dec. 26, 1606. This suggests 1605 or 1606 as the date of first production; and this is confirmed by the publication in 1605 of the anonymous *True Chronicle History of King Leir . . .* (performed 1594, 1605), which Shakespeare used as his source. Two Quartos of *King Lear* were published, in 1608 and 1619; they contain a text rather longer, but in other respects less accurate, than that of the First Folio. The main material of the play consists of a story from Celtic mythology, contained in the *Historia regum Britanniae* of Geoffrey of Monmouth (*q.v.*). It was accessible to Shakespeare in Holinshed and in Edmund Spenser's *Faerie Queene*, as well as in the earlier play.

29. In view of its allusions to topics of particular interest to James I—*e.g.*, witchcraft, in which James had long been interested; events from early Scottish history, and especially the introduction of his legendary ancestor Banquo; and references to recent events connected with the king—*Macbeth* cannot be dated before March 1603, when James VI of Scotland acceded to the English throne. The style and some minor topical allusions suggest *c.* 1605 or 1606, and a hint for the theme of the three witches may have been given by Matthew Gwinne's entertainment of the *Tres Sibyllae*, with which James was welcomed to Oxford on Aug. 27, 1605. The play was revived in 1611, when a physician and astrologer called Simon Forman tells us in his manuscript "Booke of Plaies" that he saw it at the Globe on April 20. The only extant text, that of the First Folio, bears traces of shortening and has been interpolated with additional rhymed dialogues for the witches, possibly by Thomas Middleton (*q.v.*), but the extent of Middleton's contribution has been exaggerated. For sources it is not likely that Shakespeare had consulted any Scottish history other than that included in Holinshed's *Chronicle*; he may have gathered witch lore from Reginald Scot's *Discoverie of Witchcraft . . .* (1584), or from James I's *Daemonologie* (1597).

30. It is not quite clear whether *Antony and Cleopatra* was the play of that name entered in the Stationers' Register on May 20, 1608, for no Quarto is extant, and a fresh entry was made in the Register before the issue of the First Folio. Apart from the 1608 entry there is little external evidence to fix the date of the play, but it is in Shakespeare's later, although not his last, manner and may very well belong to 1607. The second edition (1607 or ...) of Samuel Daniel's *The Tragedie of Cleopatra* shows alterations from the first (1594) that seem likely to have been inspired by Shake-

speare's play. Like *Julius Caesar, Antony and Cleopatra* is derived mainly from Plutarch's life of Mark Antony. There is no record of a 17th-century production, and the play was later eclipsed by *All For Love* (1677), a recasting of the story in the manner of neoclassical tragedy, by John Dryden (*q.v.*). Shakespeare's version was first revived in 1849.

31. For *Coriolanus* the external evidence is even scantier, and all that can be said is that its closest affinities are to *Antony and Cleopatra,* which in all probability it directly followed.

It is based on North's translation of Plutarch's life of Coriolanus. There is no record of a contemporary performance.

32. There is no external evidence as to the date of *Timon of Athens,* but it may safely be grouped by its internal characteristics with *Antony and Cleopatra* and *Coriolanus,* and there is a clear gulf between it and those that follow. It may be placed provisionally in 1607, although some critics put it next after (or before) *Lear,* which, in grandeur of poetic conception, the poetic quality of some passages, and in treating the theme of ingratitude, it closely resembles—although the dullness and lack of humour of the comic scenes are more reminiscent of *All's Well that Ends Well.* The incoherencies of its action and the inequalities of its style have prevented some scholars from accepting it as a finished production of Shakespeare, but there agreement ceases. It is sometimes, and perhaps most reasonably, regarded as an incomplete draft; sometimes as a Shakespearean fragment worked over by a second hand, either for the stage or for printing in the First Folio; sometimes, but not very plausibly, as an old play by an inferior writer partly remodeled by Shakespeare. It seems to have no direct connection with an extant academic play of *Timon,* written *c.* 1585, which remained in manuscript until 1842. The sources are partly in Plutarch's lives of Mark Antony and Alcibiades—where the story is told briefly—on which the version in Painter's *Palace of Pleasure* is based; and partly in Lucian's dialogue *Timon,* which tells the story in greater detail. Lucian was the source, direct or indirect, for the academic *Timon,* and Shakespeare's play has some points that are in Lucian but not in Plutarch, and some that appear only in the academic play. Lucian may have been the source for some unknown version of the story on which both the academic play and Shakespeare's are based.

33. Similar difficulties, equally unsolved, cling to *Pericles, Prince of Tyre.* It was entered in the Stationers' Register on May 20, 1608, and published in 1609 as "the Late and much admired Play" acted by the King's Men at the Globe. The title page bears Shakespeare's name, but the play was not included in the First Folio, and was added to Shakespeare's collected works only in the Third Folio (1663), with others which, although they also had been printed under his name or initials in Quarto, are certainly not his (*see* above). In 1608 a prose story was published, *The Painfull Adventures of Pericles Prince of Tyre . . .* This claims to be the history of the play as it was presented by the King's Men, and is described by its author, George Wilkins—a pamphleteer and novelist to whom other plays, or a share in them, have been attributed —in his "Argument" (preface) to it, as "a poore infant of my braine." The production of the play is therefore to be put in 1608 or a little earlier. It can hardly be doubted on internal evidence that Shakespeare is the author of the verse scenes in the last three acts, with the possible exception of the doggerel choruses. It is probable, although it has been doubted, that he was also the author of the prose scenes in these acts. The poverty of the first two acts has been fairly convincingly accounted for by the theory that the play is a "bad" Quarto, a memorial reconstruction by two reporters, the reporter of the last three acts having an efficiency greater than that of his colleague. It seems reasonable to allow Wilkins some connection with the play: other plays by him were produced *c.* 1607. The writing of the play cannot much have preceded publication, for the close resemblances of the style to that of Shakespeare's last plays argue for its lateness. Unless there was an earlier Shakespearean version now lost, Dryden's statement that "Shakespeare's own Muse her Pericles first bore" (*i.e.,* that *Pericles* was Shakespeare's first play) must be regarded as an error.

The story is an ancient one which exists in many versions. In all except the play, the hero's name is Apollonius of Tyre (*q.v.*). The play is directly based upon a version in John Gower's *Confessio Amantis* (1390, 1393), and Shakespeare's use of Gower as a "presenter" (or chorus) is thereby explained. But another version of the story, in Laurence Twine's *The Patterne of Painefull Adventures* (*c.* 1576, reprinted 1607), may also have been consulted.

34. *Cymbeline* shows a further development in the direction of Shakespeare's final style, and can hardly have come earlier. Simon Forman (*see* above) describes a performance of it, but without giving the date. Forman died in September 1611, and gives the dates of the other performances he describes (of *Macbeth* and *The Winter's Tale*) as 1611, but these were not necessarily first productions—and, in the case of *Macbeth,* what he saw was clearly a revival. On internal evidence, *Cymbeline* may be conjecturally assigned to 1609. It was first registered in 1623, for publication in the First Folio. The masquelike dream in Act V, sc. 4, has been thought to be an interpolation by another hand.

This play also is based upon a widespread story (*see* ROMANCE: *Other Themes*), probably known to Shakespeare in Boccaccio's *Decameron.* The historical part is, as usual, from Holinshed.

35. *The Winter's Tale* was seen by Forman on May 15, 1611, and, as it clearly belongs stylistically and thematically to the last group of plays, it may well have been first produced in that or the preceding year. A document among the Revels Accounts gives Nov. 5, 1611, as the date of a performance at court. The plot is taken from *Pandosto* (1588; reprinted 1607), a romance by Robert Greene (*q.v.*).

36. The wedding masque in Act IV of *The Tempest* has suggested the possibility that the play may have been composed to celebrate the marriage of Princess Elizabeth and Frederick V, the elector Palatine, on Feb. 14, 1613, but the Revels Accounts gives Nov. 1, 1611, as the date of a performance at court. Silvester Jourdan's *A Discovery of the Barmudas . . . ,* containing an account of the shipwreck on the Bermudas (*q.v.*) of Sir George Somers and others in 1609, was published in October 1610, and this and other contemporary narratives of Virginian colonization probably furnished the idea for the plot.

37. Critical opinion has veered away from the theory that *Henry VIII* shows the hand of an author other than Shakespeare. John Fletcher has been named as the collaborator; some have even excluded Shakespeare entirely and allotted the authorship to Fletcher (*see* BEAUMONT AND FLETCHER). The inclusion of the play in the First Folio provides strong argument for Shakespeare's having had some share in the writing. He has been considered to be responsible only for Act I, sc. 1, 2; Act II, sc. 3, 4; Act III, sc. 2, lines 1–203; and Act V, sc. 1, but by some it is thought that the Fletcherian passages merely show Shakespeare writing in the Fletcherian style. The play was probably first produced in 1613, and originally bore the alternative title, *All Is True.* It was being performed at the Globe on June 29, 1613 (perhaps the first performance), when the thatch caught fire and the theatre was burned (*see* above). The principal source was Holinshed, but Hall's *Chronicle,* John Foxe's *Book of Martyrs* (1563, enlarged 1570), and perhaps *When You See Me, You Know Me . . .* (published 1605) by Samuel Rowley (*see* ROWLEY, WILLIAM), seem also to have contributed something.

38. *The Two Noble Kinsmen.*—Of plays not generally included in modern collected editions of Shakespeare's works, the one in which he may be thought to have had most share is *The Two Noble Kinsmen,* published in a Quarto in 1634, and registered as having been performed at the Blackfriars by the King's Men, and as being written by "the memorable Worthies of their time; Mr. John Fletcher, and Mr. William Shakespeare, Gent." An analysis of the play leaves no reason to doubt this title page ascription, although some scholars have rejected it, partly because it was included in 1679 in a Folio collection of plays by Beaumont and Fletcher. The play seems to have been the result of ordinary collaboration, not of later interpolation or reworking by either. There is enough resemblance between Fletcher's and Shakespeare's styles to make it difficult to divide the play between them, but Act I, sc. 1–4; Act II, sc. 1; Act III, sc. 1, 2; and Act V, sc. 1, 3, 4, may probably be assigned to Shakespeare: the great invoca-

tions to Mars, Venus, and Diana in Act V, sc. 1, could scarcely have been written by any other poet.

The best evidence for the dating of the play is provided by the fact that the Morris dance in Act III, sc. 5 (by Fletcher), is borrowed from a similar scene in Beaumont's *Masque of the Inner Temple and Grayes Inne . . .*, given at Whitehall on Feb. 20, 1613; the play must have been written after the masque, but probably not long after, and may therefore be dated 1613. There was probably a performance of it at court *c.* 1619.

The source for the main plot of the two noble kinsmen (Palamon and Arcite) is Chaucer's *Knight's Tale;* the comic but horrifying subplot, not found in Chaucer and unlike anything else of Shakespeare's, is generally assigned to Fletcher.

III. THE POEMS

In volume, Shakespeare's nondramatic work is not considerable: it consists—apart from the songs scattered throughout the plays—of two narrative poems, slight contributions to two collections, and the sonnets.

1. The Narrative Poems.—*Venus and Adonis* was entered on the Stationers' Register on April 18, 1593, and *The Rape of Lucrece* on May 9, 1594. (The latter, when published in a Quarto in the same year, was entitled simply *Lucrece,* and is often known by this title.) Both were dedicated to the earl of Southampton (see *Life: In London,* above).

It used to be thought that Shakespeare arrived in London from Stratford with the manuscript of *Venus and Adonis* in his pocket; this is partly because, in his dedication to Southampton, he refers to it as "the first heire of my invention," but this may well mean the first of his works to be published, rather than the first to be written. It has also been noticed that the poem contains much imagery drawn from country life and rural pursuits, and this has suggested that it was written in Stratford. This type of imagery is characteristic of all Shakespeare's works, however, and particularly of the early ones. It seems likely that, like *Lucrece, Venus and Adonis* was written after Shakespeare went to London, and both poems probably owe their origin to the comparative leisure afforded to playwrights and actors by the closing of the theatres from June 1592 to April 1594, after he had already acquired some reputation as a playwright (see *Life: In London,* above).

Both poems are in long stanza forms, *Venus and Adonis* in sesta rima (a quatrain followed by a couplet), and *Lucrece* in rime royal (*q.v.*), and in both Shakespeare rivals Spenser (who had used sesta rima for his pastoral elegy *Astrophel,* published in 1586) as a master of prosody. He may have borrowed the metre for *Venus and Adonis* from Thomas Lodge's *Scillaes Metamorphosis* (1589), and it is possible that he had read Marlowe's *Hero and Leander* in manuscript. Both poems are typical in subject and style of the heroic narrative poetry of the period: the stories, taken from Ovid's *Metamorphoses* and *Fasti* respectively, occur frequently in Renaissance literature (*see* ENGLISH LITERATURE: *The Renaissance: Sonnets and Mythological Poetry*). But in *Lucrece* especially, there are flashes of the emotional power and poetic genius that were to come to full fruition in the plays. That both poems were very popular is proved by the number of editions: at least 17 are known of *Venus and Adonis* between 1593 and 1675, and 9 are extant of *Lucrece* (1594–1655).

2. Minor Poems.—In 1599 (the year of the 5th and 6th editions of *Venus and Adonis*) William Jaggard published a poetic miscellany called *The Passionate Pilgrim,* attributing it on the title page to Shakespeare. Of the 20 (or 21) short poems it contains, however, only five are certainly Shakespeare's (versions of two of the *Sonnets,* and of three sonnets from *Love's Labour's Lost*). The rest are either anonymous poems found also in other collections (where they are not attributed to Shakespeare), or poems known to be by other authors (Marlowe, Ralegh, Richard Barnfield, Bartholomew Griffin).

More interesting is the poem called *The Phoenix and the Turtle,* an elegy on an unknown pair of wedded lovers, published in 1601 in a volume by Sir Robert Chester called *Loves Martyr: Or, Rosalins Complaint,* and described on the title page as "Allegorically shadowing the truth of Love, in the constant Fate of the Phoenix and the Turtle." To Chester's poem, written to celebrate the love of his patron, Sir John Salisbury, and his wife, symbolically identified as the turtledove (Constancy), and the phoenix (Love), "are added" (to quote the title page again) "some new compositions of severall moderne writers . . . upon . . . the Phoenix and Turtle." These "Diverse Poeticall Essaies" include two attributed to Ben Jonson, one each by John Marston, Chapman, and Shakespeare, and nine of which the authors are unknown. Shakespeare's poem, untitled, but always known as *The Phoenix and the Turtle,* describes a philosophy of fully mutual love, summed up in words spoken by Reason (the poem's principal speaker): "Love hath reason, reason none," thus recognizing, rationally, a power beyond reason, and expressing, for once, what may be taken as Shakespeare's own view.

Finally, before coming to the sonnets, there are the songs from the plays. They belong to the very heart of the Elizabethan Golden Age of lyrical poetry: their variety of mood and metre, freshness of tone, beauty of imagery, and verbal felicity make them some of Shakespeare's best-loved poetry.

3. The Sonnets.—Without doubt, however, the most outstanding of Shakespeare's nondramatic work is contained in the volume registered on May 20, 1609, by the stationer Thomas Thorpe, and published in the same year with the title page inscription, *Shake-speares Sonnets. Never Before Imprinted.* In addition to 154 sonnets, the volume contains the elegiac poem in rime royal called *A Lover's Complaint.* If this is Shakespeare's, which is doubtful, it probably dates from the *Venus and Adonis* period.

In 1640 the sonnets, with poems from *The Passionate Pilgrim* and elsewhere, many of them not Shakespeare's, were republished by John Benson in *Poems: Written by Wil. Shake-speare, Gent.* Here the sonnets are arranged in a different order from that of 1609. Some are omitted, and they are altered, and given titles, and are declared by the publisher to "appeare of the same purity, the Authour himselfe then living avouched."

No other Shakespearean controversy has received so much attention as that concerning the date, character, and literary history of the sonnets; and this has been extended to a controversy about the nature of the poet's relationship with the two people to whom they are addressed—especially the "lovely boy," who is perhaps to be equated with "Mr. W. H." (*see* below). This is intelligible enough, since upon the issues raised depends the question whether or not these poems give a glimpse into the intimate depths of a personality which otherwise is at most only imperfectly revealed through the plays. On the whole, the balance of authority is in favour of regarding them as in a very considerable measure autobiographical. This view has undergone the fires of much destructive argument. The authenticity of the order in which the sonnets were printed in 1609, and even Shakespeare's authorship of some of them, have been doubted; and their subject matter has been variously explained as being in the nature of a philosophical allegory, an effort of the dramatic imagination, or a mere impersonal exercise in the forms of the Petrarchan convention. This last theory rests upon the assumption that the use of literary conventions is inconsistent with the expression of unfeigned emotions (*see* ROMANTICISM); and it is hardly to be set against the conviction which the sonnets themselves convey to the reader of the strength and sincerity of the emotional and spiritual experience out of which they were wrought. This conviction makes due allowance for the inevitable heightening of feeling in the act of poetic composition; and it certainly does not carry with it a belief that all the external events underlying the emotional development revealed in the sonnets are capable at this distance of time of inferential reconstruction. But it does accept the sonnets as reflecting a part of Shakespeare's life during the years in which they were written, and as revealing at least the outlines of a drama that played itself out, for once, not in his imagination, but in his actual conduct in the world of men and women. Exactly what this drama was—whether his relationship with the "lovely boy" was, as some maintain, openly homosexual, or merely expressed in the heightened language of an emotional immaturity—is yet one more of the Shakespearean mysteries that may never be entirely solved.

There is no advantage in rearranging the order of the 1609 volume, even if there were any basis other than that of whim on which to do so. Many of the sonnets are obviously linked to those following or preceding them; and although a few may be misplaced, the order as a whole does not jar against the reader's sense of emotional continuity—the only test that can be satisfactorily applied. The last two sonnets (153 and 154), however, are merely alternative versions of a Greek epigram on Cupid (possibly not by Shakespeare), and it would be rash to assume that the rest all have a common subject matter. On this assumption, however, they have generally been interpreted somewhat as follows. There are two series, which are more probably parallel than successive.

The shorter series (which comes after the longer in the 1609 arrangement), sonnets 127–152, appears to be the record of the poet's relations with a mistress, a dark woman with raven brows and "mourning eyes." In the earlier sonnets of this series he undertakes the half-playful defense of black beauty against the fair Elizabethan ideal; but the greater number are in a more serious vein, and are filled with a deep consciousness of the bitterness of lustful passion and of the slavery of the soul to the body. The woman is a wanton. She has broken her bed vow for Shakespeare, who is himself forsworn in loving her; and she is "twice forsworn" in proving faithless to him with other men. His reason condemns her, but his heart has not the power to throw off her tyranny. Her particular offense is that she, "a woman colour'd ill," has cast her snares not only upon him, but upon his friend, "a man right fair," who is his "better angel," and that thus his loss is double, in love and friendship. In this series occur the so-called "Will" sonnets (135–136), in which the word "will" occurs 18 times, and, in the 1609 edition, is generally capitalized and in italics. As well as being interpreted as a pun on Shakespeare's name, this has also led to a theory that the "lovely boy," Shakespeare's rival for the "dark woman's" affections, was called "Will"—a theory perhaps supported by the opening of sonnet 135

> Whoever hath her wish, thou hast thy *Will*,
> And *Will* to boot, and *Will* in over-plus;

The longer series (1–126) is written to a man, appears to extend over a considerable period of time, and covers a wide range of sentiment. The person addressed is younger than Shakespeare, and of higher rank. He is a "lovely boy," the son of a lovely mother, and has hair like the auburn buds of marjoram. This series falls into several groups, rarely separated by sharp lines of demarcation. Perhaps the first group (1–17) is the most distinct. The sonnets of this group are a prolonged exhortation by Shakespeare to his friend to marry and beget children. The friend is at the peak of his youth, and should make haste, before the rose of beauty dies, to secure himself in his descendants against "this bloody tyrant, Time."

In the next group (18–25) a more personal note is struck, and the writer assumes the attitudes at once of the poet whose genius is to be devoted to making the beauty and honour of his patron eternal, and of the friend whose absorbing affection is always on the point of assuming an emotional colour indistinguishable from that of love. The consciousness of advancing years (22) and of a fate which bars the triumph of public honour and proud titles (25), alike find their consolation in this affection. A period of absence follows (26–32), during which the thought of friendship comes to remedy the sorrows of a life "in disgrace with fortune and men's eyes."

Then (33–42) comes an estrangement. The friend has committed a "sensual fault," which is at the same time a sin against friendship. He has been wooed by a woman loved by the poet, who deeply resents the treachery but in the end forgives it and bids the friend "Take all my loves, my love, yea take them all!" for all are included in the love he has already freely given him. It is difficult to escape the suggestion that this conflict between love and friendship is the same as that which inspired some of the "dark woman" sonnets.

Another journey is filled with thoughts of the friend (43–52). This is followed by three sonnets (53–55) in which the friend's beauty and the immortality already conferred on it by the poet's verse are especially dwelt upon. Once more there is a parting (56–61), and the poet awaits as patiently as may be his friend's return to him. Again (62–65) he looks to his verse to give the friend immortality. He is tired of the world, but his friend redeems it (66–68). Then rumours of some scandal against his friend (69–70) reach him, and he falls (71–74) into thoughts of coming death, bidding his friend not to mourn long for him "for I love you so/That I in your sweet thoughts would be forgot/If thinking on me then should make you woe." In the next three sonnets (75–77), he continues to write of his love for his friend: "O know, sweet love, I always write of you,/And you and love are still my argument." But in sonnets 78 to 86, a new theme is introduced—that of the rival poet who, inspired by Shakespeare's example, has addressed verses to his patron. This rival, whose identification has exercised critics and commentators (*see* below), is described by Shakespeare as "a better spirit" (80), "that able spirit" (85), "by spirits taught to write/Above a mortal pitch. . . ," and as being nightly gulled with intelligence by an "affable familiar ghost" (86). He, with "the proud full sail of his great verse" has inhearsed Shakespeare's "ripe thoughts" in his brain, has "struck me [Shakespeare] dead"; but Shakespeare describes himself and his rival as "both your poets" (83)—suggesting, as well as jealousy, that the rivalry is in some way between equals, even friends. There is another estrangement (87–90), and the poet, already crossed with "the spite of fortune" is ready not only to acquiesce in the loss of friendship, but to find the fault in himself. The friend returns to him, but the relation is still clouded by doubts of his fidelity (91–93) and by public rumours of his "wantonness" (94–96). For a third time the poet is absent from his friend (97–99). Then comes an apparent interval, after which a love already three years old is renewed (100–104) with even richer praises (105–108). It is now the poet's turn to offer apologies (109–112) for offenses against friendship, and for some "brand" upon his name apparently due to the conditions of his profession of player. He is again absent (113), and again renews his protestations of the imperishability of love (114–116), and of his own unworthiness (117–121), for which his only excuse is in the fact that the friend was once unkind. If the friend has suffered as Shakespeare suffered, he has "pass'd a hell of time." The series closes with a group (122–125) in which love is pitted against time; and an *envoi* (126) warns the "lovely boy" that in the end Nature must render up her treasure.

4. The Mystery of "Mr. W. H."—Such an analysis of the sonnets' content can give no adequate idea of their quality, whereby the appeal of universal poetry is built up on a basis of intimate self-revelation. The human document is so legible, and at the same time so incomplete, that it is easy to understand the efforts made to throw further light upon it by tracing the identities of the "lovely boy" and the "dark woman" through his relationships with whom the poet was brought to so fiery an ordeal of soul, and even to the borders of self-abasement.

The search has generally started from the terms of a somewhat mysterious dedication prefixed by Thomas Thorpe to the first edition of 1609 (*see* illustration). The most usual interpretation of this is that the "begetter"—or inspirer—of the sonnets bore the initials W. H.; and history has accordingly been ransacked to find a W. H. whose age and circumstances might conceivably fit the conditions of the problem which the sonnets present. It is perhaps a want of historical perspective that has led to the centring of controversy on two names belonging to the highest ranks of the Elizabethan nobility, those of Henry Wriothesley, 3rd earl of Southampton, and William Herbert, 3rd earl of Pembroke.

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

DEDICATION BY THE PUBLISHER THOMAS THORPE OF THE FIRST EDITION OF THE "SONNETS," 1609

There is some evidence to connect Shakespeare with both. To Southampton he dedicated *Venus and Adonis* and *Lucrece*, and the story that he received a gift of no less than £1,000 from him is recorded by Rowe (see *Life*, above). His acquaintance with Pembroke can only be inferred from the statement of Heminge and Condell, in their dedication to them of the 1623 First Folio, that Pembroke and his brother, the earl of Montgomery, had "prosequuted both them and their Authour living, with so much favour." The personal beauty of the rival claimants and of their mothers, their amours, the attempts of their families to persuade them to marry, their relations to poets and actors, and all other points in their biographies which do or do not fit in with the indications of the sonnets have been canvassed with spirit and erudition —but with no very conclusive result. It is in Pembroke's favour that his initials were actually W. H., whereas Southampton's can be turned into W. H. only by a process of metathesis (*i.e.*, transposing the initials of "Henry Wriothesley"); and his champions have been more successful than Southampton's in producing a woman, a certain Mary Fitton (*q.v.*), who was a mistress of Pembroke's and was in consequence dismissed in disgrace from her post of maid of honour to Elizabeth I. But careful investigation of the sonnets, as regards their style and their relation to the plays, renders it almost impossible on chronological grounds that Pembroke can have been their subject. He was born on April 9, 1580, and was much younger than Southampton, who was born on Oct. 6, 1573. The earliest sonnets postulate a marriageable youth, certainly not younger than 18, an age which Southampton reached in the autumn of 1591 and Pembroke in the spring of 1598. The writing of the sonnets may have extended over several years, but as a whole they clearly belong to the years 1593–98 (or even earlier) rather than to 1598–1603. There is indeed not much external evidence available. Meres, in his *Palladis Tamia* (1598), mentions Shakespeare's "Sugred sonnets among his private friends" (*i.e.*, circulated in manuscript), but this allusion might come as well near the beginning as at the end of the series; and the fact that two, not of the latest, sonnets are included in *The Passionate Pilgrim* is equally inconclusive.

The only reference to an external event in the sonnets themselves that might at first sight seem useful is in the following lines (107):

> The mortal moon hath her eclipse endur'd,
> And the sad augurs mock their own presage;
> Incertainties now crown themselves assur'd,
> And peace proclaims olives of endless age.

This has been variously interpreted as referring to the death of Elizabeth I and the accession of James I in 1603, to the relief caused by the death of Philip II of Spain in 1598, and to the illness of Elizabeth and the threatened Spanish invasion in 1596. The "mortal moon" is generally considered to be Queen Elizabeth, but though "eclipse" may well mean "death," it is not clear whether to "endure eclipse" is to die, or to escape death. Arguments that the "mortal moon" was the hostile battle array of the Spanish Armada in 1588 (a reference to the Spanish ships being drawn up in the shape of a crescent), and that all the sonnets are to be dated before 1590, have found little critical acceptance.

Allusions, in sonnets 78–86, to the poet who rivaled Shakespeare in dedicating verses to the friend and patron have been variously interpreted. On critical grounds, "the proud full sail of his great verse" (86) can perhaps most satisfactorily be applied to Spenser, Marlowe, or Chapman, and more doubtfully, to Peele, Daniel, or Drayton. Marlowe has been rejected by those who date the sonnets after 1593—the year of his death—although it is possible to interpret the description of the rival poet as "by spirits taught to write" (86) as a reference to the success of his play *Dr. Faustus*, and to Greene's description of him as having prophetical spirits. The "affable familiar ghost" who is said to school the rival poet by night has been interpreted as a rather obscure reference to Chapman's own account of the sources of his inspiration in the dedication to one of his poems in 1594. Daniel inscribed a poem to Southampton in 1603, but none of the other poets named is known to have written either for Southampton or for Pembroke, or for any other W. H. or H. W., in any year during which the sonnets could have been written. Two minor poets, Barnabe Barnes and Gervase Markham, addressed sonnets to Southampton in 1593 and 1595 respectively, and Thomas Nashe composed improper verses for his delectation.

But even if external guidance fails, the internal evidence for 1593–98 as approximately the sonnet period in Shakespeare's life is strong. It was worked out in detail by two German scholars, Hermann Conrad (formerly Isaac), in an article in the *Shakespeare-Jahrbuch*, XIX (1884), and Gregor Sarrazin in *William Shakespeares Lehrjahre* (1897) and *Aus Shakespeares Meisterwerkstatt* (1906). Conrad's work, in particular, has hardly received enough attention from English scholars, probably because he makes the mistake of taking the sonnets in the order in which they are arranged in the German translation (1862) by Friedrich Martin von Bodenstedt, and of beginning his whole chronology several years too early in order to gratify a fantastic identification of W. H. with the earl of Essex. This, however, does not affect the main force of an argument by which the affinities of the great bulk of the sonnets are shown, on the ground of stylistic similarities, and of parallelisms of expression and theme, to be far closer to the poems and the range of plays from *Love's Labour's Lost* to *Henry IV* (*i.e.*, 1594–98) than to any earlier or later section of Shakespeare's work. This dating has the advantage of putting Shakespeare's sonnets in the full tide of Elizabethan production, which began with the publication of Sir Philip Sidney's *Astrophel and Stella* in 1591, and Daniel's *Delia* and Henry Constable's *Diana* in 1592, rather than later, during years for which this particular kind of poetry had already ceased to be modish. It is to these three volumes that the influence on Shakespeare of his predecessors can most clearly be traced; while he seems in his turn to have served as a model for Drayton, whose *Ideas Mirrour* was published in 1594. It does not of course follow that if the sonnets belong to 1593–98 W. H. is to be identified with Southampton. It is, in fact, unlikely that the publisher of the sonnets would address a great earl as "Master"; and W. H., even if above Shakespeare's rank, seems more likely not to have been of noble birth.

There is a possibility that there is an allusion to Shakespeare's romance in a poem called *Willobie his Avisa*, published in 1594, and written by an undergraduate called Henry Willoughby, of West Knoyle, Wiltshire. In this Willoughby, enamoured of an innkeeper's wife ("his Avisa"), apparently at Sherborne, takes counsel with "his familiar friend W. S. who not long before had tryed the curtesy of the like passion, and was now newly recovered of the like infection." But there is nothing outside the poem to connect Shakespeare with a family of Willoughbys, or with the neighbourhood of West Knoyle or Sherborne—although it is of interest that the commendatory verses prefixed to *Willobie his Avisa* contain the first literary references to Shakespeare by name, as the author of *Lucrece*.

Various other identifications of W. H. have been suggested, and much ingenuity has been shown by historians, critics, and literary detectives in hunting down references, searching through archives, and identifying portraits. One of the more interesting theories is Leslie Hotson's, persuasively argued in *Mr. W. H.* (1964), that the "lovely boy" was a certain William Hatcliffe (1568–1631), of Hatcliffe, Lincolnshire, who in 1587–88 was "prince of Purpoole" (*i.e.*, lord of misrule, *q.v.*), during the celebrations at Gray's Inn probably beginning at Hallowe'en and ending on the day after Candlemas (Oct. 31–Feb. 3). Hotson, dating the sonnets very early, identifies the "rival poet" as Marlowe, the "affable familiar ghost" as Greene, and the "dark woman" as Luce Morgan, one of the queen's gentlewomen during 1579–81, who later became a harlot. In "proving" his theory, Hotson throws much light on Elizabethan manners and customs, use of symbols, and concepts of love and friendship, but, like those of the many others who claim to have "solved the mystery," his explanations are almost too neat to be wholly convincing.

Another school of thought holds that Mr. W. H. was not the "friend" of the sonnets at all, but someone who might have procured the manuscript of them for Thorpe. Sir Sidney Lee identified him with one William Hall, himself a printer, and this explanation has also been applied, rather more plausibly, to Sir William Harvey

(Hervey), the third husband of Southampton's mother, who might have procured the sonnets for Thorpe. (Hotson, assuming William Hatcliff to be the sonnet's "begetter" in the sense of "inspirer," has the best of both worlds by concluding that he also gave the manuscript to Thorpe, thus doubly "begetting" them.) The stumbling-block to acceptance of this theory, however, whoever may be identified as the "procurer" of the sonnets for press, is the intended sense of Thorpe's dedication: it seems certain that the person to whom Thorpe "wishes" eternity and he to whom the poet "promised" eternity are one and the same. The mystery of Mr. W. H. will probably never be solved to everybody's satisfaction, and some may agree with the view of one critic, that its solution would "deprive us of one of the most enjoyable of literary pastimes." (E. K. C.; J. Cw.; X.)

IV. SHAKESPEAREAN STUDIES

A. Literary Criticism

Attempts to interpret Shakespeare's work have, in important ways, controlled and modified literary criticism in English. The plays have continued to be enjoyed whether whole, cut, or adapted, and the response of each age has governed its attitude to literary and aesthetic principles.

Ben Jonson was the first who had to account both for his own and his generation's appreciation of Shakespeare, and for his critical impatience, which resulted from a literary genius and an attitude to literature, especially to drama, very unlike that of Shakespeare (*see* also *Life: Prosperity and Fame*, above). Jonson, a classical scholar of keen, sardonic intellect, a conscious artist and satirist, was concerned both to correct the extravagance of the Elizabethans, and to castigate and reform the morals and conduct of his own age. Both he and, later, Dryden, the supreme poet and dramatist of a neoclassical age, spoke with two voices about Shakespeare, mingling praise for his achievement with disapproval of his aims and methods: their classicism (or neoclassicism) was checked by their instinctive appreciation of Shakespeare's mastery, and this caused them to reexamine their critical principles. Jonson saw bombast and lack of art in Shakespeare the dramatist, and, in his famous appraisal of him in his *Timber, or Discoveries* (written *c.* 1630; *see* above), clearly distinguished himself from those who praised Shakespeare uncritically, honouring his memory "on this side (*i.e.*, below) idolatry." Yet, in his verses for the First Folio, he could, himself "idolatrously," put him above the Greeks and Romans, not only (to borrow words used later by Milton) as a warbler of "native woodnotes wild," but as an artist.

This half line from Milton's "L'Allegro," with its implication that Nature had guided the unscholarly pen of the poet, dogged criticism for two centuries. So the author of the prologue to Shakespeare's *Julius Caesar* (printed, without the author's name, but early ascribed to Dryden, in *Covent Garden Drolery* . . . , 1672), wrote:

> His Excellencies came and were not sought,
> His words like casual Atoms made a thought:
> Drew up themselves in Rank and File, and writ,
> He wondring how the Devil it were such wit.

This may or may not be Dryden's verse, but it does express one of the opinions also expressed in his *Essay of Dramatick Poesie* (1668):

> All the Images of Nature were still present to him, and he drew them not laboriously, but luckily . . . Those who accuse him to have wanted learning, give him the greater commendation: he was naturally learn'd; he needed not the spectacles of Books to read Nature; he looked inwards, and found her there.

Like Jonson, and annoyed by the same elements in Shakespeare, Dryden yet recognized in him the "largest and most comprehensive soul" among "all Modern, and perhaps Ancient Poets," and Pope's preface to his edition of the plays in 1725 follows Dryden in this.

The easily accepted Platonic notion of a poet possessed by the muse continued to militate against a recognition of Shakespeare's conscious artistry, and a succession of works on his education, from Richard Farmer's *Essay on the Learning of Shakespeare* (1767) to T. W. Baldwin's *William Shakespeare's "Small Latine and Lesse Greeke"* (1944), speak for the liveliness of this interest. So, inferentially, do the Baconian and other theories (see *Anti-Shakespearean Theories*, below).

Meanwhile, the 18th-century editors and critics accumulated information on the writers of Shakespeare's time and on his sources, stimulated by Farmer's essay, which had used these for its own purposes. They wrote about Shakespeare's failure to observe the classical unities, his lack of rhetorical "decorum," his quibbles (puns), indecencies, and anachronisms; blemishes were indicated and beauties marked. Samuel Johnson's preface to his 1765 edition, a commanding work surveying the plays and summing up and transcending the issues of the age, while "placing" Shakespeare securely, decided the controversy about the unities, said wise things about the relation of the tragic to the comic, but still balked at the Shakespearean quibble: "A quibble was to him the fatal Cleopatra for which he lost the world, and was content to lose it." The "world" lost is fidelity to nature, and the approbation of an age that recognized in Shakespeare this fidelity above all else: as Johnson himself said, earlier in his preface, "Shakespeare is above all writers, at least above all modern writers, the poet of nature; the poet that holds up to his readers a faithful mirrour of manners and of life."

Walter Whiter defended the quibble in *A Specimen of a Commentary on Shakspeare* . . . (1794), unappreciated in its own day but recognized as important in the 1930s when his points had been made all over again. Stressing the unconscious and associative origin of many puns, he touched on Shakespeare's creative processes, isolated image clusters, and hinted at an awareness of what Caroline Spurgeon (*see* below) came to call "iterative imagery." Shakespeare is, however, no more an artist for being exhibited as a slave of the associative process, and Whiter's apologetic tone is true to his period which, important as it is for its scholarly work, is more concerned with adjudication than interpretation. In surveying 18th-century Shakespearean scholarship and criticism as a whole one sees chiefly promise and prophecy: a clearing of the way.

One work must be excepted: Maurice Morgann's *An Essay on the Dramatic Character of Sir John Falstaff* (1777). This book, important and influential historically, is as wise and broad in its argument as it is vital in its expression. There had been essays in the periodicals of the 1750s on the Shakespearean characters; Johnson had made pertinent comments on them in the notes to his edition; and William Richardson's *A Philosophical Analysis and Illustration of some of Shakespeare's Remarkable Characters*, more intent on indicating casebooks of experience for the benefit of the reader than on psychological analysis, had appeared in 1774; but Morgann's essay transcends these (and also its immediate issue: the courage or cowardice of Falstaff) in its large, liberal, and refreshing response to the plays. Shakespeare, he says: "boldly makes a character act and speak from those parts of the composition, which are *inferred* only, and not distinctly shewn. This . . . seems to carry us beyond the poet to nature itself. . . ." This capacity in Shakespeare for seeing his characters as "*whole*, and as it were original," not imitated, "rather as Historic and Dramatic beings," was central to his purpose, and it remains true despite the critical perversions which have stemmed from it. With Thomas Whately's detailed comparison of *Richard III* and *Macbeth* (*Remarks on some of the Characters of Shakespeare*, 1785) it became clear, that "the distinction and preservation of *character*" were of first importance to 18th-century critics, and this insistence was to prevail throughout the 19th century and into the 20th. It informs the works of William Hazlitt, S. T. Coleridge, F. J. Furnivall, Edward Dowden, A. C. Bradley, Harley Granville-Barker, and John Dover Wilson.

William Hazlitt, admiring Whately's analysis, published his *Characters of Shakespear's Plays* in 1817. It is an excellent handbook; it has an air of novelty and adventure, its author being (like all the Romantics) more conscious of differences from his predecessors than of a tradition. Enthusiastic, reverential, intuitively perceptive, he has a flair for apt quotation and, coming to Shakespeare as a dramatic critic, he is saved from some of the pitfalls of a purely literary study of character.

Coleridge's lectures on Shakespeare had been delivered before

Hazlitt's book appeared, but though they share a certain interest in character, the poet's critical range is far beyond that of his contemporaries and releases us from the 18th-century modes of thought. He was concerned to recognize Shakespeare's powers of judgment and to see him as a conscious artist. He claimed to have argued in a lecture course in 1802 that "Shakespeare's judgment was . . . still more wonderful than his genius, or rather, that the contradistinction itself between judgment and genius rested on an utterly false theory" (*The Canterbury Magazine*, September 1834). This recognition, and the further one that every work of art must be judged by its own organic laws, put an end to the balancing of faults against beauties. Coleridge directed attention to the poems, used before (when read at all) only as quarries for parallel passages, and he analyzed *Venus and Adonis* in chapter 15 of his *Biographia Literaria* (1817). Examples from Shakespeare illuminated his distinction between the imagination and fancy, and both he and Keats, as great poets themselves, revealed much about Shakespeare's creative processes.

The 20th century has seen, indeed, deep affinities in the creative minds of Keats and Shakespeare. Keats's letters are permeated with an awareness of the dramatist, and his attribution to Shakespeare of that envied "negative capability"—"when a man is capable of being in uncertainties, mysteries, doubts, without any irritable reaching after fact and reason" (*Letter to G. and T. Keats*, Dec. 21, 1817)—has proved fruitful.

Less fruitful have been the disputes about precedence and originality in the Romantic movement, and it is more relevant to recognize that a philosophic temper stimulated, in Germany and England, certain approaches and presumptions. G. E. Lessing (*q.v.*) recognized Shakespeare's closer affinity with the Germanic spirit and literature than with the French rules; the prose translations of 22 of the plays by C. M. Wieland (*q.v.*), published during 1762–66; and those in verse (1797–1810, completed by others, 1821–23), of A. W. von Schlegel (*q.v.*), were enthusiastically seized on, and the latter's *Über dramatische Kunst und Literatur* (1809–11; English translation, 1815) explored the Coleridgean world. The philosophical significance of character became central, Shakespeare's profundity as a formal artist was acclaimed, and a leading idea was seen to inform his work as a whole. When this root idea was analyzed in particular plays (for example, in Hermann Ulrici's analyses in *Shakespeares dramatische Kunst*, 1839; Eng. trans. 1876) the interpretation was often profitable, but there was in German criticism of this period the kind of insensitivity to language that made Schlegel accept *A Yorkshire Tragedy* as Shakespeare's without qualms, and a lack of knowledge—more serious, even, than that among English writers—about the circumstances in which the plays were written and their stage origins. Schlegel has, however, fine things to say on particular plays.

In the Victorian period no major critic wrote on Shakespeare. Victor Hugo and Swinburne enthused eloquently, but the first original interpretative work was Walter Pater's, in three essays published in his *Appreciations* (1889). Scholarship, industry, and scientific method were to the fore. Shakespeare societies were begun in England (1840) and Germany (1865), and their published proceedings embody the virtues and faults of the time. Edmond Malone's work on the order of the plays (see *Chronology of the Plays*, above) was supplemented, and interest in Shakespeare's development as a poet and dramatist through the four periods established by Furnivall's verse tests was stimulated: the reach of the whole was surveyed. The dominant work here is Dowden's *Shakspere: a Critical Study of His Mind and Art* (1875). Investigation of Shakespeare's spiritual biography as revealed in the plays persisted into the early 20th century, but the great book then was A. C. Bradley's *Shakespearean Tragedy* (1904). Here is the culmination of all character analysis. Bradley's very greatness, and the finality with which some of his statements were received, have irked later critics, and they have overinsisted on his obsession with character, neglect of the poetry, and unawareness of Elizabethan stage conventions. He irritated most when he pursued characters far beyond the circumstances of the play, or subordinated plot and action to psychological study, or, preoccupied with the moral order at the root of tragedy, sentimentalized some of the issues. But his chapters remain as a necessary counterbalance to the works of the interpreters who reacted against him.

This reaction typifies 20th-century criticism. Sir E. K. Chambers, whose *William Shakespeare: a Study of Facts and Problems* (two volumes, 1930), remains a standard work, brought to the study of Shakespeare's life and plays an unrivaled knowledge of the medieval and Elizabethan stage, and a study of the dramatic conventions of that stage inspired a new school of critics. L. L. Schücking's *Die Characterprobleme bei Shakespeare* (1919; Eng. trans., 1922) and E. E. Stoll's *Art and Artifice in Shakespeare* (1933) are representative works. Dramatic realism, they argue, rightly, is not that of actual life; and inconsistencies of character are best explained in terms of Elizabethan practice and convention. Much of this was salutary for a generation later accused of putting its faith in dramatic realism. It is even necessary as a corrective to the criticism of Granville-Barker (*q.v.*; *Prefaces to Shakespeare*, 1927–48), which was healthy in that it came from a dramatist-actor-producer who had illuminated Shakespeare's art in stage presentation, but limited in its reliance on Bradley and in an underlying predilection for the naturalistic theatre.

A further aspect of historical research was the investigation of Elizabethan physiological psychology. R. L. Anderson's *Elizabethan Psychology and Shakespeare's Plays* (1927), L. B. Campbell's *Shakespeare's Tragic Heroes: Slaves of Passion* (1930), and L. Babb's *The Elizabethan Malady: a Study of Melancholia in English Literature from 1580 to 1642* (1951) demonstrate the range of studies in this kind; studies that are either stimulating and corrective or stultifying and peripheral according to the author's application of his thesis.

One may recognize as a counterblast to historical criticism the contribution of the psychoanalysts. Far from wishing to explain away inconsistencies of characterization, these critics positively welcomed them. J. I. M. Stewart's *Character and Motive in Shakespeare* (1949) discussed the general critical issues arising, and the same year brought Ernest Jones's *Hamlet and Oedipus* (a revision of chapter one of *Essays in Applied Psycho-Analysis*, 1921), a development of ideas prompted by Freud. Specifically Freudian inspiration apart, there is no doubt that the popularization of theories of the unconscious and the mysteries involved in motivation brought a sense of freedom to the interpretation of literature in general and Shakespeare in particular. A wider freedom is claimed by Lascelles Abercrombie, who says that "anything which may be found" in Shakespeare's art, "even if it is only the modern reader who can find it there, may legitimately be taken as its meaning" (*A Plea for the Liberty of Interpreting*, British Academy annual Shakespeare lecture, 1930). His lecture answered the so-called "disintegrators" who, led by J. M. Robertson (1856–1933), had apportioned out plays or parts of plays, deemed to fall below some elusive, subjective standard, to other dramatists. Those elements which Shakespeare adopted and absorbed, Abercrombie argued, became his and were open to interpretation with the rest.

The freedom demanded by Abercrombie had already been exercised. L. C. Knights's article "How Many Children Had Lady Macbeth?" (1933; reprinted in *Explorations*, 1946) reacted against Bradley, and focused a movement which had begun with the early works of John Middleton Murry and George Wilson Knight, and in the researches of Caroline Spurgeon. These writers, conscious that character analysis was not enough, in their various ways redirected attention to the poetry and symbolism. L. C. Knights argued that "we start with so many lines of verse on a printed page," and that we have to "allow full weight to each word, exploring its 'tentacular roots'." (This direction should be seen against the critical and poetical background of the 1920s and 1930s, with its emphasis on the image and on ambiguity, its re-interpretation of the metaphysical poets, and its response to the poetry and criticism of T. S. Eliot. A critical discipline can be seen evolving, sympathetic to Knights's aims and molded by the thought of I. A. Richards, T. S. Eliot, William Empson's *Seven Types of Ambiguity* [1930], and F. R. Leavis; *see* CRITICISM: *The New Criticism.*) Beginning indeed with the "printed page," Caroline Spurgeon card-indexed Shakespeare's images and used them

interpretatively. The most brilliant and influential discovery in her work was that of the "iterative image," and in *Shakespeare's Imagery and what it tells us* (1935) she pointed to prevalent groups of images which characterize the individual plays and unconsciously fashion our response to them. Like Whiter, she indicated clusters of images peculiar to Shakespeare, and these were used to throw light on his creative processes and to guide the attribution of scenes and plays to him. W. H. Clemen, in *Shakespeares Bilder: Ihre Entwicklung und ihre Funktionen im dramatischen Werk* (1936; translated and enlarged as *The Development of Shakespeare's Imagery*, 1951), studied with insight Shakespeare's dramatic use of metaphor.

The impressive and original body of work produced by G. Wilson Knight is historically linked with this school of criticism, but is more free ranging. Actor, producer, and (later) dramatist, he regards each play "as a visionary unit bound to obey none but its own self-imposed laws," and his examination relates each "given incident or speech" either to "the time sequence of story or the peculiar atmosphere, intellectual or imaginative, which binds the play" (*The Wheel of Fire*, 1930). The "symbolic overtones" are revealed. His method radically redirected the attention of the student and freshly interpreted in particular, perhaps, *Measure for Measure*, the Roman plays, *Timon of Athens*, and the last romances. Emphasis on the image has made the business of interpretation more laborious. A book on each play has become common; among the best have been two by Roy Walker on *Hamlet* and *Macbeth* (*The Time is Out of Joint*, 1948; *The Time is Free*, 1949), and Robert Heilman's on "Image and Structure in King Lear" (*This Great Stage*, 1948).

The so-called "new criticism," characterized by close linguistic analysis, has had its brilliant successes. Its excesses, too, have been flagrant, and opposition has taken the form of a move nearer to Bradley, or another kind of historical criticism. Rosemond Tuve (in *Elizabethan and Metaphysical Imagery*, 1947) attacked the Caroline Spurgeon approach; Sister Miriam Joseph (in *Shakespeare's Use of the Arts of Language*, 1947) pointed to the poet's studied use of the rhetorical figures; and John Holloway, in a number of critical articles culminating in the introduction to his *The Story of the Night* (1961), expressed disquiet about the "current coin of Shakespeare criticism," "its vocabulary of metaphor," and its refusal to examine the fundamentals of its method, with its implication that there is only one valid approach to dramatic writing. Moreover. a wider knowledge of the thought and beliefs in his day, demonstrated in such works as Hardin Craig's *The Enchanted Glass* (1936) and E. M. W. Tillyard's *The Elizabethan World Picture* (1943), valuably checked and controlled any tendency to think peculiar in Shakespeare what was common to his age. Scholarly work on the sources of the plays has also intensified, again with the implication that the ardent critic may overstress the liberty of interpreting. Scholarship and interpretation have, however, happily come more nearly into alliance than at any time since Johnson's day. New editions of the plays are in the hands of enlightened critics. An interpretative work, however, roving over all the relevant fields of knowledge and research and surveying (as Johnson could) Shakespeare's achievement, is unlikely to appear. One is thrown back on Heminge and Condell's First Folio preface: ". . . his wit can no more lie hid, then it could be lost. Read him, therefore; and againe, and againe . . ."

(G. A. O.; X.)

B. Textual Criticism

The textual critic of Shakespeare needs to know about the status of the various texts, and their value as evidence; the language of Shakespeare's time; Shakespeare's idiosyncrasies as a writer; and the barrier which an Elizabethan, or Jacobean, printer might be likely to erect between the manuscript "copy" and the printed text.

1. Texts.—Modern knowledge of the status of the Folio and Quarto texts, and some of the problems involved—for example, that of the "bad" Quartos—have already been discussed under *The First Folio and the Quartos*, above. The last collected Folio edition of the plays (F4) was published in 1685; thereafter editors aimed at making Shakespeare more accessible to the reader by printing the works in smaller format, in several volumes. They also aimed, from the 18th century onward, at elucidation and amendment of the text, by comparison of earlier editions (the Folios and Quartos), and by a study of Shakespeare's period, and of the works of his contemporaries. Important collected editions of the works have been published as follows:

1709	Nicholas Rowe: 6 vol. Based largely on F4; notable for adding stage directions, completing lists of *dramatis personae* for every play, and as containing the first life of Shakespeare.
1725	Alexander Pope: 6 vol. Based on Rowe, collated with some Quarto texts.
1733	Lewis Theobald: 7 vol. The first scholarly edition.
1744	Sir Thomas Hanmer: 6 vol. Based on Theobald.
1747	William Warburton: 8 vol. Based on Theobald.
1765	Samuel Johnson: 8 vol. Based on Warburton, with valuable preface (see *Literary Criticism*, above).
1767–68	Edward Capell: 10 vol. Based on the collection and collation of Quarto texts, and research on Elizabethan literature.
1773	George Steevens: Johnson's text, with quotation from Shakespeare's contemporaries; greatly enlarged in the 2nd edition, 10 vol. (1778).
1790	Edmond Malone: 10 vol. Important for its "Attempt to ascertain the order in which Shakespeare's plays were written," and the first use of the Revels Accounts, Henslowe's Diary, and other contemporary records.
1795–96	Samuel Johnson (Philadelphia): 8 vol. (1st U.S. edition).
1803	First Variorum: 21 vol. The 5th edition of the Johnson-Steevens text of 1773, edited after Steevens' death by Isaac Reed, and containing three volumes of introductory matter: prefaces by earlier editors, Malone's account of the English stage, extracts from Henslowe's Diary, etc.
1813	Second Variorum: 21 vol. A reprint of the First Variorum.
1818	Thomas Bowdler: 10 vol. The so-called *Family Edition*, suitably "bowdlerized."
1821	Third Variorum, also known as "Boswell's Malone": 21 vol. An edition planned by Malone, and finished after his death by James Boswell the Younger. Incorporates the prolegomena to the first two Variorum editions, with Malone's life of Shakespeare, The "Attempt . . . ," and an essay on Shakespeare's phraseology and metre. Unlike Variorum I and II, and earlier editions, it contains the *Poems*.
1842–44	J. P. Collier: 8 vol.
1857	Alexander Dyce: 6 vol. 3rd edition (1895–1901): 10 vol.
1853–65	J. O. Halliwell-Phillipps: 16 vol. A scholarly Folio edition.
1863–66	W. G. Clark, W. Aldis Wright, and J. Glover: 9 vol. The Cambridge edition. Revised, 1891–93.
1864	Clark and Wright: 1 vol. The Globe edition. Based on the Cambridge.
1871–	New Variorum, edited by H. H. Furness *et al.* The most comprehensive edition; supplementary volumes bring early volumes up to date.
1880–81	H. N. Hudson: 20 vol. Harvard edition.
1886–1906	A. Morgan *et al.*: 22 vol. Bankside edition. Parallel texts.
1888–90	Henry Irving edition: 8 vol. with full stage history of each play.
1899–1924	General editors: W. J. Craig, R. H. Case *et al.* Arden edition; 1 vol. for each play. 37 vol.
1918–28	General editors: W. L. Cross, C. F. T. Brooke *et al.* Yale edition: 1 vol. for each play. 40 vol.
1921–63	General editors: Sir Arthur Quiller-Couch, J. Dover Wilson *et al.* New Cambridge edition. 1 vol. for each play.
1937–	G. B. Harrison: Penguin Paperback edition. 1 vol. for each play.
1938–	General editors: R. E. C. Houghton *et al.* New Clarendon edition. 1 vol. for each play.
1951	Peter Alexander: 1 vol.
1951–	General editors: Una Ellis-Fermor (until her death in 1958), H. F. Brooks, H. Jenkins *et al.* New Arden edition. 1 vol. for each play.
1951	Hardin Craig: 1 vol.
1954–	General editors: H. Kökeritz, C. T. Prouty *et al.* Revised Yale edition. 1 vol. for each play.
1956–	General editor: A. Herbage. Pelican Paperback edition.
1958	P. Alexander: 3 vol. Heritage Shakespeare.
1960–	General editor: L. B. Wright. Folger Library Paperback edition.

New methods of printing in the 19th century led to a new development: the production of facsimiles of the early editions. Important facsimiles include:

Of the Quartos:

1862–76	Edited by J. O. Halliwell-Phillipps, 48 vol. Lithographic.
1880–89	The Griggs-Praetorius Quarto Facsimiles, general editor, F. J. Furnivall, 43 vol. Photolithographic.
1939 *et seq.*	By W. W. Greg, for the Shakespeare Association. Collotype.

Of the First Folio:
1862–64 Edited by L. Booth, 3 vol. Type facsimile.
1876 Edited by Halliwell-Phillipps. Reduced facsimile. Photo-lithographic.
1902 The Oxford Facsimile, ed. by Sir Sidney Lee. Collotype.
1955 The Yale Facsimile, ed. by H. Kökeritz and C. T. Prouty. Reduced facsimile. Photographic.
Of the Four Folios:
1904–10 Published by Methuen. Photozincographic.
Of the Poems:
1905 Edited by Sir Sidney Lee. Collotype.

Of the editors who preceded him, W. A. Wright wrote in 1893, almost certainly with some excess of charity:

> And it is a study of great interest to follow them as they exercise their varied talents on the noblest field which the literature of their country afforded: Rowe, himself a dramatist of no mean skill; Pope, with his deep poetic insight; Theobald, with his fine tact and marvellous ingenuity; Hanmer, whose guesses, however they may pass the sober limits of criticism, are sometimes brilliant, often instructive, and never foolish; Warburton, audacious and arrogant, but now and then singularly happy; Johnson, with his masculine common sense; Capell, the most useful of them all, whose conscientious diligence is untiring, whose minute accuracy is scarcely ever at fault; Steevens, Malone, . . . Boswell, . . . with all their varied learning; together with their successors of the present generation in England, Germany and America, who have devoted themselves to the illustration of Shakespeare as to a labour of love.

It would be unfair to suggest that the earlier editors, from Rowe onward, did not interest themselves in the establishment of a correct text; but by modern standards they worked by hit-or-miss systems, and sometimes substituted their own (often excellent) tastes for critical principles. They tended to assemble as many various readings, from various editions, as possible, and to use their own judgment as to which was the best. Considering their methods their success was striking. (*See* also articles on many of the individual editors.)

The editors of the Cambridge Shakespeare seem to have been the first to make a reasonable attempt to list the early editions and to sort out the relationships between them. Their critical apparatus of variant readings and emendations remains unsurpassed. The Globe edition provided a standard text which modern scholars find impossible to dislodge: this is the text generally used for quoting line numbers. The almost impeccable Booth type facsimile of F1 placed much necessary information before the public, and remains the handiest edition. The Griggs-Praetorius Quarto facsimiles should have been even more reliable, but Aldis Wright has demonstrated that they had undergone remarkable tinkering (one "facsimile" of a 1595 edition contains words foisted in from a 1619 edition), and that no confidence can be placed in their punctuation. The critical introductions to some of these Quarto facsimiles, however—notably those by P. A. Daniel—are of great value. The Sidney Lee F1 facsimile, though less portable than the Booth, may be said to replace it on the score of reliability. The Kökeritz and Prouty facsimile of F1 has been faulted, in that the photographic reproduction sometimes omits punctuation. The collotype facsimiles of the Quartos under the general editorship of W. W. Greg are trustworthy.

The path of the Shakespearean textual critic used to contain the major stumbling-block of the problem of the early Quartos (the so-called "bad" Quartos; see *The First Folio and the Quartos*, above) of certain plays: *Romeo and Juliet, Henry V, Hamlet, The Merry Wives of Windsor*, 2 and 3 *Henry VI, Richard III*, and *King Lear*, in which the disparity between the earlier and later texts is remarkable. Rival explanatory theories long disputed the field: either that here were early versions later revised by Shakespeare (the *Henry VI* plays being, it was suggested, the work of earlier, cruder dramatists), or that the corrupt texts were versions of stage performances taken down in shorthand. These theories were eventually routed by W. W. Greg, A. W. Pollard, J. Dover Wilson, and Peter Alexander (see *Bibliography*), who established that the "bad" Quartos are the result of reconstruction from memory by actors of texts to add to the repertories of near-derelict traveling theatrical companies, not, as had been earlier suggested, that the shorthand writers worked at the behest of fraudulent, stealthy, and injurious publishers. Philip Edwards (in "An Approach to the Problem of *Pericles*," *Shakespeare Survey*, number v, 1952) convincingly suggested that *Pericles* should be added to the "bad" Quartos: it differs from the others in that it is the work [illegible] two reporters of widely different skill, and in that no good vers[illegible] has ever been found to replace the existing "bad" Quarto [illegible] The shorthand writer theory was given its deathblow by [illegible] Duthie's *Elizabethan Shorthand and the First Quarto of King Lear* (1950). The relative quality of the Quartos of *Richard III* and *King Lear* is so good that no satisfactory explanation of them has been offered, but there is general agreement that the former is a memorial reconstruction, whilst the *Lear* text may be basically a "surreptitious" transcript (*see* A. Walker, *Textual Problems of the First Folio*, 1953).

General attacks on the editorial problem began in three of the annual Shakespeare lectures of the British Academy: A. W. Pollard, *The Foundations of Shakespeare's Texts* (1923), W. W. Greg, *Principles of Emendation in Shakespeare* (1928), and R. B. McKerrow, *The Treatment of Shakespeare's Text by His Earlier Editors, 1709–1768* (1933). McKerrow's *Prolegomena for the Oxford Shakespeare: a Study in Editorial Method* (1939) is a full-dress discussion of the problems; the author's death prevented publication of any of the projected edition. Greg's *The Editorial Problem in Shakespeare* (1942) carried the discussion further; in it, and in *The Shakespeare First Folio: Its Bibliographical and Textual History* (1955), he laid before the scholar convincing arguments to support a theory of the text for every one of the plays. There is no starkness of simplicity in his findings. For no two plays, it seems, is the history of the text the same. F. T. Bowers *On Editing Shakespeare and the Elizabethan Dramatists* (1955) is a valuable manifesto of analytical bibliography.

Two of the less complicated text histories may be given as examples. For *Romeo and Juliet*, the first edition (1597; Q1) is a "bad" Quarto. Q2 (1599) is an authoritative text printed, it is thought, from a Shakespeare autograph. Q3 (1609) is printed from Q2. Q4 (undated, but probably 1619) is printed, with [illegible]ous but apparently unauthoritative changes, from Q3. F1 is printed from Q3. Later researches have led to a theory that a pen-corrected example of Q1 may have been used as copy for [illegible] which complicates a hardly pellucid situation with theories th[illegible] good text was contaminated by a bad one. For *Titus Andron[illegible]* Q1 (1594) seems to have been set from a Shakespeare autogr[illegible] Q2 (1600) from Q1, Q3 (1611) from Q2. F1 was printed from [illegible] with the addition of Act III, sc. 2, which is absent in all [illegible] Quartos, and must derive from an authoritative manuscript [illegible]plications arise from the fact that printer's copy for any of [illegible] plays may have been any one of the following: Shakespeare's [illegible] copy, his rougher "foul papers," fair copies apparently made [illegible] known scribe) especially for use in the printing house, theatr[illegible] prompt copies, earlier editions corrected by pen and ink [illegible] manuscripts of various status, etc.

An important development for Shakespearean textual criticism was the general acceptance of the view that three pages in [illegible] manuscript "Booke of Sir Thomas Moore" (British Mus[illegible] Harleian MS. 7368) are in Shakespeare's handwriting—the [illegible] certainly known example of it except for the six legal signa[illegible] (see *Life*, above). This view, suggested in the 1870s, was [illegible] thoroughly discussed by A. W. Pollard, W. W. Greg, E. [illegible] Thompson, J. Dover Wilson, R. W. Chambers, and others [illegible] *Shakespeare's Hand in the Play of Sir Thomas More* [illegible] which brought forward paleographic, orthographic, linguistic, [illegible]listic, and psychological evidence to support the identification [illegible] despite much controversy, and a frenzy of attempts during [illegible] 1920s and '30s to solve all textual problems by an appeal to Sha[illegible]speare's calligraphic style as here revealed, it has proved help[illegible] the elucidation of disputed readings, and is thus a valuable aid [illegible] modern editors of the plays.

Under the influence of Pollard, Greg, and McKerrow, a number of new editions of single plays have been published. Peter Alexander's one-volume edition (1951) is probably the most satis[illegible] complete text. The New Cambridge Shakespeare, begun [illegible] J. Dover Wilson and Sir Arthur Quiller-Couch with *The Tem[illegible]* (1921), and carried on by Dover Wilson and others after Q[illegible] Couch's death in 1944, has provided a number of stimulating [illegible]

controversial texts. Some of the New Arden (1951 *et seq.*) editions of single plays, each by a different editor, have evidently been influenced by the new bibliographical methods; others have not.

2. The Language of Shakespeare's Time.—The 18th-century editors of Shakespeare, particularly Theobald, Johnson, Capell, Steevens, and Malone, were aware that much of Shakespeare's language was obsolete, and so not easily intelligible to 18th-century readers, and as a result they made considerable study of the work of Shakespeare's contemporaries. Several glossaries and illustrative notes on Shakespeare's language were published. Knowledge of Elizabethan English was greatly advanced by *A Glossary: or, Collection of Words, Phrases, Names . . . in the Works of English Authors, particularly Shakespeare and his Contemporaries* (1822), by the philologist, and keeper of manuscripts at the British Museum, Robert Nares.

By the mid-19th century, various scholarly societies (*e.g.*, the Camden Society, founded 1838; the Shakespeare Society, 1840; and the Percy Society, 1840) had begun the reprinting of a considerable body of Elizabethan literature. Among the leaders in this were J. P. Collier (*q.v.*) and J. O. Halliwell (later Halliwell-Phillipps), two of the founders of the Shakespeare Society, but Collier was led, by zeal for scholarship or some other motive, to extensive forgeries to support his theories and textual emendations, and Halliwell was suspected of the theft of manuscripts from the library of Trinity College, Cambridge. These lapses, although they resulted in the winding-up of the Shakespeare Society in 1853, do not prevent modern Shakespearean scholars from acknowledging a considerable debt to both. The reprinting of Elizabethan literature was continued by the New Shakespeare Society, founded by F. J. Furnivall (*q.v.*) in 1873; it lasted until 1894.

Other 19th-century works on Shakespeare's language were E. A. Abbott's *A Shakespearian Grammar* (1869), and Alexander Schmidt's *Shakespeare-Lexicon* (1874–75; revised by G. Sarrazin, 1902). In 1874, too, began the publication of the *New English Dictionary* (N.E.D.; later the *Oxford English Dictionary*, O.E.D., completed in 1928), which owed much to the labours of the reprinters who had disseminated earlier English writings, and which, in its turn, is an invaluable aid to Shakespearean scholars. Based on the N.E.D. was C. T. Onions' *Shakespeare Glossary* (1911, revised 1919), and this, with the N.E.D., and Schmidt's *Lexicon*, laid the foundations for later work on Shakespeare's language. New directions, with implications for the text, were explored in H. Kökeritz' *Shakespeare's Pronunciation* (1953).

3. Shakespeare's Idiosyncrasies.—Knowledge of those matters in which Shakespeare differed from his contemporaries—versification, language, methods of thought, methods of composition, etc.—is necessary for the establishment of his text. Here, however, agreement among scholars is not easy, and subjective thinking and personal taste—or prejudice—play a large part. Scholarly aids of the highest value can be found in the great *Concordance to Shakespeare* (1894) of John Bartlett (keyed to the Globe text), and its still useful pioneer predecessor (*Complete Concordance to Shakespeare*, 1844–45) by Mrs. Cowden Clarke. Studies of Shakespeare's education, methods of writing, use of images, and use of sources, continue to be made (see *Literary Criticism*, above). It is impossible to sum up the findings of the researchers; as yet no clearly recognizable pattern in the Shakespearean carpet emerges.

4. Shakespeare and His Printers.—The modern scholar, presented with a text of Shakespeare, wants to know what relationship it bears to the author's manuscript, and hopes to be told how he can reconstruct that manuscript from it. Much of the effort made to satisfy him has been described above. Considerable activity however, continues among those who, like Greg and many other scholars mentioned, are interested in what happened in an Elizabethan printing house. McKerrow's *Introduction to Bibliography for Literary Students* (1927) remains the starting-point for such investigations.

The first serious examinations of the First Folio came from Sir Sidney Lee, in his introduction to the Oxford Facsimile (1902), and other writings; and from Pollard and Greg, largely in their attempts to traverse his theories. Appreciable headway began to be made with E. E. Willoughby's *The Printing of the First Folio of Shakespeare* (1933). Using a variety of new techniques, Willoughby was able to reconstruct many of the day-to-day events in Jaggard's printing house while F1 was being printed. The later work of Charlton K. Hinman (*see* below) and J. W. Shroeder (published in *The Great Folio of 1623*, 1956) destroyed the validity of some of Willoughby's work, but his achievement remains of value.

The key question would once have seemed to be "What did printers do to texts?" Willoughby showed that this question must be narrowed to the particular printers dealing at a particular time with a particular text. Hinman saw that any given line of type in F1 was set up by an individual compositor, possibly a different man from the one who composed a given line on the next page, and by a variety of techniques (including use of an instrument for the mechanical collation of two copies of a single book—known as the Hinman collating machine—and the elaboration of methods for distinguishing between the work of different compositors) he reached a stage of knowing far more of what went on in Jaggard's shop in 1623 than Jaggard himself could ever have known.

Hinman's findings began to be made available in the 1950s, and his methods were put to good use by other scholars, notably Fredson T. Bowers and Alice Walker. The latter, concentrating on the evidence provided by Hinman's methods that made it possible to identify the various compositors working on the First Folio, established that two (known as A and B), distinguishable by their spelling, were liable to different sorts of error in setting type from copy. Finally, with the publication of Hinman's *The Printing and Proof-Reading of the First Folio of Shakespeare* (2 vol., 1963), it became possible also to identify three other compositors—C, D, and E—and to conclude that E, whose hand is seen in the section of the Folio containing the tragedies, was a raw apprentice, not regarded as capable of setting type from a manuscript copy, but only from one previously printed.

Furthermore, Hinman's new and scientific methods, used to collate the 79 copies of the First Folio collected at the Folger Shakespeare Library, Washington, D.C., made it possible to reconstruct the details of Jaggard's printing and proofreading procedures, and revealed that, by modern standards, the methods used when producing the First Folio were haphazard in the extreme. For instance, the method of setting up the type not by successive pages, but in sets of 3 sheets, doubled to form 6 leaves and 12 pages, with the consequent need to estimate from copy where each page would begin and end, led to miscalculations of length, especially if the compositors were working from annotated copy, so that they were obliged to split lines of verse to fill up gaps, to print verse as prose to save space, and to omit or insert stage directions.

But perhaps the most important discoveries relate to proofreading. Hinman demonstrated that the pages were read and corrected while the printing was in progress, and that to form any one copy of the Folio, both corrected and uncorrected sets of three sheets, not necessarily in order of printing, were collected and bound together. Thus, it seems likely that no two copies of the First Folio were identical. From those available it is clear that few proof corrections were made—only on 134 of the 900 pages of the First Folio are any to be found, and on those only an average of fewer than four corrections a page were made. The proofreader was clearly chiefly interested in typographical niceties, and usually applied his wit to the correcting of substantive errors, rather than consulting copy; in fact, only two indubitable cases of the printer's having consulted copy in making a correction were claimed by Hinman.

Thus, it can be seen that the results of his work for textual criticism were twofold: the opening up of new possibilities of research into the idiosyncrasies of compositors; and the development of a new, and justifiable, eclecticism in dealing with disputed readings.

V. ANTI-SHAKESPEAREAN THEORIES

The idea that Shakespeare's plays and poems were not actually written by William Shakespeare of Stratford has been the subject

of many books and is widely regarded as at least an interesting possibility. The source of all doubts about the authorship of the plays lies in the disparity between the greatness of Shakespeare's literary achievement and his comparatively humble origin, the supposed inadequacy of his education, and the obscurity of his life. In Shakespeare's writings men have claimed to discover a familiarity with languages and literature, with such subjects as law, history, politics, and geography, and with the manners and speech of courts, which they regard as inconceivable in a common player, the son of a provincial tradesman. This range of knowledge, it is said, is to be expected at that period only in a man of extensive education, one who was familiar with such royal and noble personages as figure largely in Shakespeare's plays. And the dearth of contemporary records has been regarded as incompatible with Shakespeare's eminence, and as therefore suggestive of mystery. That none of his manuscripts has survived has been taken as evidence that they were destroyed to conceal the identity of their author.

1. The Claims Put Forward for Bacon.—Though earlier writers had expressed skepticism about Shakespeare, the first identification of the author as Francis Bacon, viscount St. Albans, seems to have been made *c.* 1785 by the Rev. James Wilmot, rector of Barton-on-the-Heath, Warwickshire. Wilmot communicated his views to J. C. Cowell of Ipswich, whose account of the matter is contained in a manuscript in the University of London library (*see* Allardyce Nicoll, "The First Baconian," in the *Times Literary Supplement*, Feb. 25, 1932). A letter from Sir Toby Matthew to Bacon contains the statement, "The most prodigious wit that ever I knew . . . is of your Lordship's name, though he be known by another," and this has been regarded as proof of Bacon's pseudonymous writings. Their similar treatment of references from the Bible, the law, and the classics has made Bacon a candidate for the authorship of the plays. The first published statement of this theory was W. H. Smith's *Was Lord Bacon the Author of Shakespeare's Plays?* (1856), which set on foot the Bacon-Shakespeare controversy. W. S. Melsome (*The Bacon-Shakespeare Anatomy*, 1945) found references in Shakespeare's plays to works by Bacon not published during Shakespeare's lifetime, which therefore he could not have seen; from this Melsome concluded that, as only Bacon could have known of these unpublished works, he must have written the plays containing references to them. Another method of investigation was used by I. Donnelly who, in *The Great Cryptogram: Francis Bacon's Cypher in the so-called Shakespeare Plays* (1887), found ciphered messages embedded throughout the plays that proved Bacon's authorship. Sir E. Durning-Lawrence (*Bacon is Shakespeare*, 1910) discovered in *Love's Labour's Lost* the word "honorificabilitudinitatibus," which forms the anagram *Hi ludi F. Baconis nati tuiti orbi* ("These plays, the offspring of F. Bacon, are preserved for the world"). Others carried this cryptographic line of investigation further, but the professional cryptologists W. F. and E. S. Friedman examined all the Baconian ciphers and rejected them as invalid (*Shakespearean Ciphers Examined*, 1957). Several societies and periodicals devoted to the Baconian claims were founded at the end of the 19th century, but interest later declined.

2. Other Candidates.—For several years after the appearance of his *Shakespeare Identified in Edward de Vere, the 17th Earl of Oxford* (1920), the views of J. T. Looney attracted enough adherents to lead to the formation of Oxfordian societies in London and New York. Looney argued from the biographical similarity of Bertram (in *All's Well That Ends Well*) and of Hamlet to Oxford himself, and also from the resemblance of Oxford's poems to Shakespeare's early work. Oxford's interest in the drama extended beyond noble patronage, for he himself wrote some plays, although there are no known examples extant. His 22 acknowledged poems were written in youth, and, as he was born in 1550, Looney argued that they were the prelude to his mature work, and that this began in 1593 with *Venus and Adonis*. This theory is supported by the coincidence that Oxford's poems apparently ceased just before Shakespeare's work began to appear. It is claimed that Oxford assumed a pseudonym in order to protect his family from the social stigma attached to the stage, and also because extravagance had brought him into disrepute at court. (*See* also OXFORD, EDWARD DE VERE, 17th Earl of.)

Another candidate is William Stanley, 6th earl of Derby, whose claims were advanced by A. W. Titherley (*Shakespeare's Identity: William Stanley, 6th Earl of Derby*, 1952). He was keenly interested in the drama and became the patron of his own company of actors; and his elder brother, Ferdinando (the 5th earl), was, as Lord Strange, patron of the company to which Shakespeare belonged (see *Life: The Missing Years*, above). Several poems written early in the 1580s exhibit signs of an immature Shakespearean style, yet cannot well have been written by Shakespeare. One is in Derby's handwriting, and three ("Of silver pure thy penne is made, dipte in the Muses well"; "What shall I say of Gold, more than tis Gold?"; "My thoughts are winged with hopes, my hopes with love") are signed W. S.; these initials have been thought to conceal Derby's identity, and to have been expanded later into "William Shakespeare." Derby's motive for this self-concealment would have been, like Oxford's, to avoid the association of his family name with the stage, then regarded as low in the social scale.

A theory put forward by C. Hoffman in *The Man Who Was "Shakespeare"* (1955; U.S. title, *The Murder of the Man Who Was "Shakespeare"*) identifies Shakespeare with Marlowe. Marlowe's influence on Shakespeare's early work has long been recognized, and it has even been suggested that he collaborated with Shakespeare in some of the plays, but Hoffman has discovered stylistic and linguistic similarities throughout the Shakespeare canon. He has also noticed that Shakespeare emerged from obscurity with the publication of *Venus and Adonis* in September 1593, less than four months after Marlowe was stabbed to death at Deptford. Because Marlowe's avowed "atheism" and probable homosexuality are known to have incurred religious and political disapproval Hoffman argues that when the privy council ordered Marlowe's arrest, his friend and patron Sir Thomas Walsingham (cousin of Sir Francis Walsingham) evolved an elaborate plan for his escape. Two of Walsingham's servants murdered an unknown man and alleged the body to be that of Marlowe, while Marlowe fled to France and thence to Italy. He continued to write in exile, his work being sent to Walsingham, who arranged for it to be transcribed and paid Shakespeare to "father" it. The original manuscripts were thought to be buried with Sir Thomas Walsingham at Chislehurst, Kent, but when the tomb was opened in 1956 they were not found. (*See* also MARLOWE, CHRISTOPHER.)

Sir G. G. Greenwood (*The Shakespeare Problem Restated*, 1908) and others, although not venturing to identify the "true" author, have nevertheless vigorously disputed Shakespeare's claim to the title.

3. The Case for Shakespeare.—It can hardly be maintained that no difficulty exists. In spite of recorded allusions to Shakespeare as the author of many plays in the canon, made by about 50 men during his lifetime, it is arguable that his greatness was not as clearly recognized in his own time as might be expected. But, on the other hand, the difficulties are not so great as disbelievers have held, and their proposals have raised larger problems than they have resolved. The difficulty, inasmuch as it exists, can only be viewed profitably in the light of extensive knowledge of the conditions under which plays were written, produced, and preserved, and of the prevailing attitudes toward authorship in general, in the period *c.* 1590 to *c.* 1612.

Shakespeare's origin raises no difficulties, for poets and men of genius arose in his age, as in others, from all social levels. Of his education more must be said. Stratford possessed a grammar school of better than average quality, which was free for the sons of burgesses, and this included Shakespeare (*see* above). That we can point to no documentary evidence of his attendance there would be significant only if his name were missing from existing records of attendance, but no such records are known, and it is doubtful that they ever existed. Though we have no specific knowledge of the curriculum of the Stratford school, we can infer it with some confidence from that of other schools, and from the degree of uniformity found among these. The assumption is, then, that Shakespeare spent some years in a good school, and that he

acquired (there and elsewhere) some competence in Latin, some acquaintance with Ovid, Virgil, Cicero, Horace, Livy, Quintilian, and other classical authors, and a familiarity with parts of the Bible and with the Book of Common Prayer, together with a thorough grounding in Christian ethics. As Virgil K. Whitaker has shown (*Shakespeare's Use of Learning*, 1953), the Latin authors whom we should expect a boy from a good grammar school *c.* 1575 to know are just those with whom Shakespeare shows some familiarity in his earliest plays and poems. Neither in these nor in his later works does he reveal knowledge of a large number of books, Latin or English, or a scholar's knowledge of those relatively few books more or less well known to him. Likewise, his knowledge of the law as reflected in his plays has been shown (by P. S. Clarkson and C. T. Warren, *The Law of Property in Shakespeare and the Elizabethan Drama*, 1942) to be neither so broad nor so accurate as that of "about half of Shakespeare's fellows." Similarly, his acquaintance with history was not extensive; his knowledge of English history appears to have been limited to what he found in those portions of Holinshed, Hall, and other works which he mined for the purposes of his own history plays. On his ignorance of geography (or carelessness about it), as shown by his famous reference in *Twelfth Night* to the "sea-coast of Bohemia," he was twitted by Ben Jonson. As for the accuracy of the reproduction in the plays of the speech and manners of courtiers, which has been thought to provide evidence of their author's high birth, this would be difficult to challenge in the absence of authentic records of conversation and comportment at the courts of Elizabeth I and James I: we form our impressions of how such persons talked at least in part from the plays of the time. How Shakespeare attained his unparalleled insight into human nature must remain a mystery, and it will scarcely be maintained that university education or noble birth have in general been of much service in this direction. Everyone agrees that the author of Shakespeare's plays was a man of extraordinary genius, endowed with brilliant powers of observation and an unexampled ability to synthesize what he experienced (directly or in books), and to give to it artistic shape.

The often repeated assertion that we know almost nothing about Shakespeare's life must be tested historically. We are entitled to suspect the presence of a mystery in the dearth of knowledge of Shakespeare's daily life, personality, and opinions (as compared with those of, say, William Wordsworth or Robert Browning) only if we find that he is unusual in this respect among dramatists of his day. But this is not the case. It is true that we know more about Ben Jonson, but this is clearly because, beside being a dramatist and actor, Jonson was a scholar, a literary critic, the leader of a poetic school, a writer of court and city masques, a man often involved in troubles which became matters of record: indeed, a quarrelsome and colourful public figure. With the exception of Jonson, we know more about Shakespeare than about any other dramatist of the time. Stage plays were not regarded as serious literature by the Elizabethans, and their writers were not lionized. Much of our comparative ignorance about the dramatists must be attributed to the fact that it was not an age of biography or casual letter writing, of journalism or advertising.

These facts have bearing upon the disappearance of Shakespeare's manuscripts. Once a play was in print, the manuscript possessed no value except for the acting company that owned it: by whom it would be altered and amended, roughly handled, and probably in the end, destroyed. There was no custom of collecting the autograph manuscripts of particular writers (*i.e.*, those written in their own hand). Moreover, because paper was a costly, imported commodity, manuscripts were in demand for many practical uses, all in themselves destructive. It is not surprising, therefore, that we have no manuscript in the handwriting of Shakespeare or any one of his fellow dramatists, of any successful professional public stage play printed before 1640: such manuscripts as have survived, even in the writing of copyists, are of "academic" plays; *i.e.*, plays produced in universities and schools.

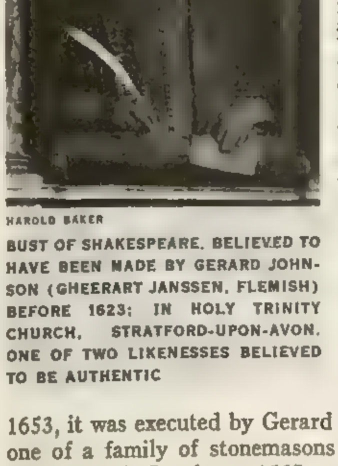
From 1598 onward, Shakespeare is named as author on the title pages of the Quarto editions of the separate plays and poems generally attributed to him, and of the Folio editions of the collected plays. Shakespeare's contemporaries wrote of him unequivocally as the author of the plays. Ben Jonson, who knew him well, contributed verses to the First Folio of 1623, where (as elsewhere) he criticizes and praises Shakespeare as the author. John Heminge and Henry Condell, fellow actors and theatre owners with Shakespeare, signed the dedication and a foreword to the First Folio, and described their methods as editors. In his own day, therefore, he was accepted as the author of the plays. Throughout his lifetime, and for 150 years after, no person is known to have questioned his authorship. In an age that loved gossip and mystery as much as any, is it conceivable that Jonson and Shakespeare's theatrical associates shared the secret of a gigantic literary hoax without a single leak, or that they could have been imposed upon without suspicion? Unsupported assertions that the author of the plays was a man of great learning and that Shakespeare of Stratford was an illiterate rustic no longer carry weight, and only when a believer in Bacon or Oxford or Marlowe produces sound evidence will scholars pay close attention to it and to him. (G. E. D.)

VI. PORTRAITS OF SHAKESPEARE

The problems surrounding the details of Shakespeare's life and work extend also to his portraiture. Only two of the many supposed representations of him can be regarded as authoritative, and neither is a portrayal direct from life. This, and the fact that they differ in some essential features, has encouraged acceptance of numerous portraits of wholly different types. The result has been a series of portraits which may be classed as: (1) genuine portraits of Shakespeare's period of persons not Shakespeare but like various conceptions of him; (2) memorial portraits based on originals believed to be genuine; (3) portraits of persons, both known and unknown, deliberately faked to resemble Shakespeare, or some conception of what he looked like; (4) complete fabrications and forgeries.

The two portraits (neither of them of great artistic merit) that can be accepted as authentic are the bust (really a half-length statue) on the wall monument in Holy Trinity Church, Stratford-upon-Avon; and the copperplate engraved by Martin Droeshout (1601–*c.* 1650), whose father, a Flemish engraver, settled in London *c.* 1590, as the frontispiece for the First Folio (1623).

1. The Stratford Bust and Monument.—These must have been erected on the north wall of the chancel between 1616, when Shakespeare died, and 1623, for, in his verses for the First Folio, Leonard Digges refers to the "Stratford *Moniment*." The monument, mainly of white marble, inlaid with black panels, consists of a central arch, in which the bust stands, flanked by two Corinthian pillars of black marble with gilt capitals and bases, supporting a cornice. The cornice holds a square block containing Shakespeare's arms, helm, and crest; above is a skull, and on each side, a cherub. One cherub represents Rest, the other Labour. Below the arch is a tablet, on which is the inscription. The bust, showing Shakespeare full face, with his hands holding pen and paper and resting on a tasselled cushion, is of soft Cotswold limestone.



HAROLD BAKER

BUST OF SHAKESPEARE. BELIEVED TO HAVE BEEN MADE BY GERARD JOHNSON (GHEERART JANSSEN, FLEMISH) BEFORE 1623: IN HOLY TRINITY CHURCH, STRATFORD-UPON-AVON. ONE OF TWO LIKENESSES BELIEVED TO BE AUTHENTIC

In design the monument is typical of the period: according to an entry by the antiquarian Sir William Dugdale in a diary for 1653, it was executed by Gerard Johnson—*i.e.*, Gheerart Janssen, one of a family of stonemasons from Amsterdam, whose father had settled in London *c.* 1567, and who had a workshop on Bankside. The bust is said to have been commissioned by John Hall,

Shakespeare's son-in-law, and he must, presumably, have approved it; Shakespeare's widow must also have seen it. It has been suggested that it was modeled from a death mask; it is certainly a portrait, not merely a conventional generalization.

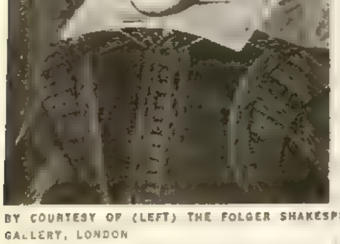
As was usual, especially in the memorial work of Flemish sculptors of the Jacobean period, the bust was originally coloured, and this probably explains the lack of detail in the carving; the detail (*e.g.*, of eyebrows, which are scarcely indicated by the chisel; and of teeth, represented by a solid surface) was supplied by the paintbrush. The high colouring, especially of the face, and of the dark hazel eyes, auburn beard and hair; scarlet doublet; black gown; and crimson and green cushion is responsible for the bust's somewhat wooden, artificial appearance.

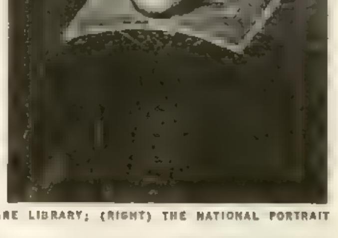
The bust was repaired and restored in 1748, and in 1793 Edmond Malone, the Shakespearean scholar and editor, brought it back to what he thought to have been its original state by having it painted "a good stone colour." In 1861, this was removed, and the original colouring restored. There is no sign of any breakage and repair of the nose, although an apparently unusually long upper lip has been attributed to such a breakage; actually, this appearance is mainly an optical illusion, resulting from the smallness of the nose and the thinness of the moustache.

Theories that the monument and bust are not those originally set up have been brought forward to explain its many dissimilarities from the engraving of it in Dugdale's *Antiquities of Warwickshire* (1656), but many other engravings in this book are demonstrably inaccurate, and there is no reason to doubt that the bust and monument now in the church are those set up between 1616 and 1623.

2. The Droeshout Print.—The importance of the portrait by Droeshout is that it was commissioned by John Heminge and Henry Condell (Shakespeare's fellow-actors and first editors), as the frontispiece to the first collected edition of his plays (the First Folio, 1623). The volume itself was to be his real "monument," but as the whole work was regarded as a memorial undertaken by Shakespeare's friends in a spirit of pious veneration, it may be assumed that the engraving was thought to be a satisfactory likeness. Anne Shakespeare must have seen it; Ben Jonson extolled it—though his verses may be regarded as merely conventional praise.

The original from which the print was made can scarcely have been drawn from life by Droeshout, but he probably worked from a lost line drawing by an unknown artist, showing Shakespeare as a young man. It has been deduced from the strong highlights and shadows of the head, and from the fact that the body is out of scale with it, and the dress out of perspective, that this original was probably a shadowless outline drawing of the head only, and that the chiaroscuro, body, and dress were unsuccessfully added by the young and inexperienced Droeshout. This theory (first propounded by Sir George Scharf in *On The Principal Portraits of Shakespeare*, 1864) is supported by the existence of





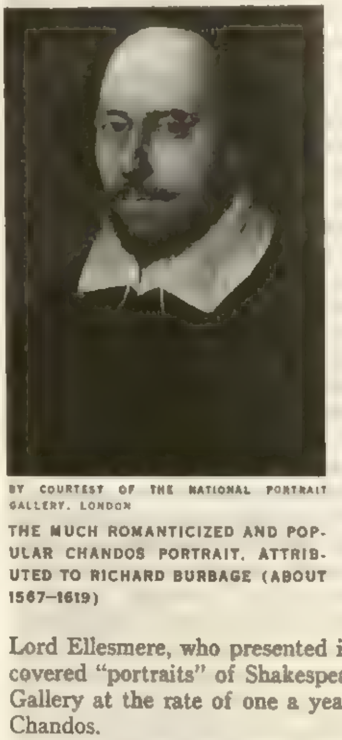
BY COURTESY OF (LEFT) THE FOLGER SHAKESPEARE LIBRARY; (RIGHT) THE NATIONAL PORTRAIT GALLERY, LONDON

(LEFT) FIRST PROOF AND (RIGHT) PRINTED VERSION OF THE ENGRAVED PORTRAIT OF SHAKESPEARE MADE BY MARTIN DROESHOUT AS THE FRONTISPIECE TO THE FIRST FOLIO, IN 1623. THE FIRST PROOF IS THOUGHT TO BE THE BETTER LIKENESS

copies of the first proof of the engraving. The first such proof to be discovered was acquired by J. O. Halliwell-Phillipps in the 1870s, and, with another, is now in the Folger Shakespeare Library, Washington, D.C. There is another in the British Museum, London, and one in the Bodleian Library, Oxford. In the proof—thought to be probably the best extant likeness of Shakespeare—the head is far more human than in the First Folio frontispiece as printed; the bone structure of the other features corresponds to that of the nose (which is longer than in the Stratford bust); and the moustache is thin and wiry.

3. Other Portraits.—The existence of the first proof of the Droeshout engraving has undermined the claim that the Flower portrait (presented by a Mrs. Charles Flower to the Shakespeare Museum, Stratford, in 1895, and now in the Stratford Memorial Theatre) is the original from which Droeshout worked: the Flower portrait resembles the second, printed, stage of the engraving, not the proof. It was probably painted from the Droeshout print, perhaps in the first half of the 17th century, and may be the earliest painted portrait of Shakespeare.

The portrait that has made the greatest appeal, because it suits popular ideas of what Shakespeare ought to look like, is the Chandos, in the National Portrait Gallery, London. The romantic, Italian-looking head differs greatly in appearance from that of the Stratford bust and the Droeshout print, and the facial measurements do not agree. According to a doubtful tradition, it was painted by Richard Burbage, who gave it to his fellow-actor Joseph Taylor, who bequeathed it to Sir William Davenant, Shakespeare's godson; but this story is strongly suspect. The esteem in which it was held within 70 years of Shakespeare's death is proved by the fact that Sir Godfrey Kneller made a copy of it to give to Dryden, acknowledged in Dryden's *Fourteenth Epistle* (1694). In Malone's time it was in the possession of the earl of Fitzwilliam, and, inherited by the duke of Buckingham and Chandos, in 1847 it was sold to Lord Ellesmere, who presented it to the nation. The newly discovered "portraits" of Shakespeare sent to the National Portrait Gallery at the rate of one a year generally tend to resemble the Chandos.



BY COURTESY OF THE NATIONAL PORTRAIT GALLERY, LONDON

THE MUCH ROMANTICIZED AND POPULAR CHANDOS PORTRAIT, ATTRIBUTED TO RICHARD BURBAGE (ABOUT 1567–1619)

After the Stratford bust, there seems to have been no statuary portrait of Shakespeare until 1740, when the statue in the Poets' Corner, Westminster Abbey, was set up by public subscription organized by the earl of Burlington and Alexander Pope, among others. Designed by William Kent, and executed by the popular Flemish sculptor, Peter Scheemakers (15 of whose monuments are in the abbey), it is based on the Chandos portrait, as is the statue by L. F. Roubillac, commissioned by David Garrick in 1758, and left by him to the British Museum. (M. H. S.; X.)

VII. SHAKESPEARE THE DRAMATIST

Shakespeare's powers as a dramatist have been demonstrated beyond all doubt by the success of his plays in performance. His plays are performed throughout the world; his birthday is honoured by many nations; and his quatercentenary in 1964 was the occasion of worldwide celebrations. He is the one universal playwright, accepted in countries with diverse ideologies, religions, and artistic conventions and standards: in Canada, Ceylon, China, and Czechoslovakia; in India, Israel, Italy, and Japan; in the U.S.S.R. and the United States.

Shakespeare did not achieve this universal appeal by promulgating ideas. *Coriolanus* and *Julius Caesar* may sometimes have

given political offense, but to both sides of a political debate. The history plays may be seen as supporting a kind of monarchical government now found only in very few countries, and as giving more importance to "providence" in human affairs than to other factors—economic, ideological, or racial—on which many have placed more importance. But ideas are not dominant, nor is "meaning" unequivocal. Shakespeare's plays appeal to thinking men, but do not obviously direct their thoughts; in this they differ from the works of, for example, Aeschylus, Molière, Ibsen, Shaw, and many other dramatists.

The most obvious and general appeal of the plays derives from Shakespeare's power to create intrinsically interesting situations and plots. These enable a wide range of characters to be opposed or contrasted; and the action displays their antagonisms and attractions so that a full gamut of reactions is expressed, and the deeper instincts of human nature exposed. There are opportunities for sober argument and fantastic wit, for dreamlike and for waking reality. Moreover, the action is so displayed that it holds attention. One proof of this power of plot and situation lies in the many adaptations made from Shakespeare's plays into other art forms: into prose narratives, operas, musical dramas, into ballets without words, and radio plays or recorded readings without visual effects, into films and television dramas. The situations, plots, and characters seem endlessly interesting. They have yielded new plays too: innumerable rewritings of *Romeo and Juliet;* Bertolt Brecht's version of *Richard III* in *Arturo Ui;* thinly-disguised borrowings from *Hamlet* in Anton Chekhov's *The Seagull.* Sometimes they have encouraged formal experiment, as in W. H. Auden's *The Sea and the Mirror,* a poetic "commentary on Shakespeare's *The Tempest,*" written as spoken by the various *personae* from the drama. With the immediate and localized interests of situation and plot larger issues are involved, so that Shakespeare's plays can be described in archetypal or symbolistic terms: it can be said that the trial scene in *The Merchant of Venice* opposes mercy and justice; that *Hamlet* places an individual against society, a son against father and mother, a moment against destiny; that *A Midsummer Night's Dream* juxtaposes innocence and experience, elemental beings and mortals, imagination and reason. Shakespeare chose basic stories of man's search for assurance, or knowledge, or integrity; of purgation, reconciliation, communion.

The intrinsic interest of the action of Shakespeare's plays is most readily discovered in their diverse *dramatis personae,* some of whom have become proverbial—as, for instance, a Shylock, a Hamlet, a Falstaff. But the settings in which the figures appear are also arresting. The Elizabethan theatre had no stage scenery in the modern manner (*see* THEATRES [STRUCTURES]) but by changes of costume, by groupings, behaviour, and verbal implication, Shakespeare ensured that in performance his plays would realize a series of particular backgrounds. The movements from Venice to Cyprus, and from public places to private, in *Othello;* from castles to heath, seashore, and battlefield in *Lear;* from the court of Sicilia to the countryside of Bohemia in *The Winter's Tale;* or, in *Hamlet,* from the battlements to the interiors of the castle at Elsinore, to the open country, to the graveyard, and back again to the court, are all large dramatic devices with an appeal that is instinctive and powerful because it relies on sense-impressions rather than intellectual or psychological perceptions. The Elizabethans called their plays "shows" for good reason: at their best, in Shakespeare's works, they not only spoke, but also demonstrated or displayed; and they presented not merely individual human beings in action but large views as well. Proof of this achievement lies in the way in which Shakespeare's plays have appealed to those 19th- and 20th-century theatrical managers who have sought to make "spectacles" of the poetic drama: entrances and exits are often elaborate and potentially meaningful; intimate scenes and soliloquies alternate with crowd scenes involving general movement; and casual, informal, scenes with ceremonies and rituals. Such producers as Henry Kemble, Charles Kean, Max Reinhardt (*q.v.*), Sir Tyrone Guthrie, and Peter Brook have amply demonstrated the power of these devices; so that sometimes in their productions such elements seem to overshadow others. But even in the barest or most inexperienced production the sweeping effects of movement and setting speak for Shakespeare.

The radio and phonograph have demonstrated the opposite pole of the plays' attractions—the astonishing vitality of the words. Shakespeare's verse form gives continuity and control of tempo. Allied to his use of rhetorical devices, it can sustain a moment, hold the drama still in verbal and almost musical elaboration so that its implications and power may grow in the minds of the audience. In verse and prose, Shakespeare weighted single syllables, or set one rhythm against another. And with words of complex meaning and images of wide or precise associations he displayed thematic, psychological, or "atmospheric" subtleties. He mixed formal and deliberate speech with the quick and colloquial, and so familiarized the remote and lent power and significance to the familiar. In the 20th century the astonishing "poetic texture" of the dialogue has often drawn attention from other aspects of Shakespeare's dramaturgy, so that the silent study or the classroom has sometimes seemed the proper place for admiring his works.

Perhaps the most astonishing fact in considering Shakespeare's dramatic art is that a writer who has so satisfied the subtle literary critics has also satisfied the most realist actors, and often with the same element of his art, the dialogue. For his "lines" are eminently actable; in general, they can both be spoken as poetry and also serve as one element in a full realization of a role in performance. Verbal complexity is used to show conscious and subconscious thought at one and the same time; so, clearly, in *Twelfth Night,* Viola speaks for herself as well as for Cesario (the name she has assumed when disguised as a man, and servant of the duke, Orsino, with whom she is in love) when she talks to Orsino of the sister who died for love (Act II, sc. 4); more subtly, Macbeth reveals his own sense of guilt in asking if the murderers are "so gospelled" that they will kill Banquo (Act III, sc. 1). The actor can present two levels of consciousness: Hamlet, in talking (Act II, sc. 2) of the Tragedians of the City who are coming to Elsinore, may also voice his own deeper desire when he says that the "lover may not sigh gratis," that "the humorous man shall end his part in peace . . . and the lady shall say her mind freely . . ."; and in his repeating of the words "mobled queen" from the player's speech describing the death of Priam and the anguish of his wife Hecuba, the words are revalued, so that Hecuba may become his mother Gertrude to the audience, as she is to Hamlet in his deepest thoughts. Such opportunities are numerous; if all were taken a performance would be overfilled, and the imagination of the actor overstretched. So it is that Shakespeare's major roles can be interpreted in many ways; there is such a wealth of opportunity that each actor may select what best suits his physique and inspiration. Malvolio (in *Twelfth Night*) may be comic, or dignified, or pathetic; Hamlet philosophical or active, neurotic or resolute. Even a comparatively small-scale character like Olivia in *Twelfth Night* can be interpreted as the conventional "widow" that a member of an early audience saw, as the elegant, sad lady of numerous productions, as an impetuous minx, or as a rather frightened girl; and such a full-scale character as Shylock can satisfy the widely differing powers of a Macklin, a Kean, or an Irving, or in our own time, of a Donald Wolfit, an Alec Guinness, a John Gielgud, or a Peter O'Toole.

The scope of a role does not depend on words alone, for there are moments for which Shakespeare has chosen gesture or mere physical presence as the primary means of impressing character-in-action. The most famous example is the stage direction in *Coriolanus* (Act. V, sc. 3), *"He holds her by the hand, silent,"* indicating the simple movement that answers the power of Volumnia's many words—and, indeed, her physical presence. When Macbeth first sees the witches (Act I, sc. 3) his reaction is silence, and it is Banquo who speaks to them; and, again, when they have spoken, he is silent, and continues so after Banquo (with the words "Good sir, why do you start and seem to fear/Things that do sound so fair?") has identified the physical response that dominates the stage as one of fear. At the end of the tragedy, in the penultimate scene, Macbeth's last contribution is the wordless fight with Macduff (indicated by the stage direction "Exeunt

fighting . . . re-enter fighting and exeunt. Macbeth exit falling"); and, beyond this, the final impression he makes comes at the very end of the play, when his "cursed head"—a painted stage-property—is held aloft by Macduff. Shakespeare "realized" the characters of his dramas at several levels of consciousness, in their physical and instinctive as well as in their mental or emotional reactions, and in the effect of their mere presence or image on the other characters, and audience. The progress of the play's action reveals character with progressive clarity and penetration; one of the major structural devices is a progressive revelation of psychological truth, a casting away of masks, a growing perception—for the audience if not for the character himself—of basic and seldom-named desires.

In many ways Shakespeare might seem limited by the primitive nature of his instrument. To Elizabethans, the wooden "O" (the circular auditorium and central, uncurtained stage) had to stand for the fields of France, and a boy actor for Juliet. But time has proved that he was not so restricted. Obviously, he turned to good account the speed and chameleon qualities of his stage, and the agility and clarity of his boy actors, but large scenic resources and the full sensibility and power of a great actress do not cause his plays to seem crippled; they extend themselves easily into wider areas of realization. The secret of this is perhaps the final secret of Shakespeare's art as a dramatist, the element we can readily identify, but only with greatest difficulty analyze. His plays are not confined by his theatrical instruments, nor by the thought and manners of his age, nor even by a particular form of dramatic construction, because while mastering the techniques of his art Shakespeare seems to have been constantly concerned to reflect the world in which he lived, to make the variously and richly attractive characters-in-action a "mirror held up to nature." Johnson put this magisterially:

> Shakespeare's plays are not in the rigorous and critical sense either tragedies or comedies, but compositions of a distinct kind; exhibiting the real state of sublunary nature, which partakes of good and evil, joy and sorrow, mingled with endless variety of proportion and innumerable modes of combination. (Preface to Shakespeare's *Works*, 1765.)

Greg, *A Bibliography of the English Printed Drama to the Restoration*, 4 vol. (1939–59). *See* also the *Shakespeare-Jahrbuch* (1865–); *Shakespeare Quarterly* (1950–); *PMLA* (1884–); *The Year's Work in English Studies* (1920–); bibliographical supplements to *British Book News*, 58, 129, 138, 140, 143, 146 (1955 *et seq.*); *Shakespeare Survey* (1948–). On early editions, etc. *see* H. C. Bartlett, *Mr. William Shakespeare, Original and Early Editions of His Quartos and Folios, His Source Books and Those Containing Contemporary Notices* (1922); H. C. Bartlett and A. W. Pollard (eds.), *A Census of Shakespeare's Plays in Quarto, 1594–1709* (1916; rev. ed. 1939). Useful handbooks are H. Granville-Barker and G. B. Harrison (eds.), *A Companion to Shakespeare Studies* (1934); F. E. Halliday, *A Shakespeare Companion, 1550–1950* (1952; revised 1964); L. Marder, *His Exits and His Entrances: the Story of Shakespeare's Reputation* (1963).

Editions: As well as those listed under *Textual Criticism* above, the following are useful: The Stratford Town Edition, by A. H. Bullen, 10 vol. (1907); the Caxton Edition, by Sir Sidney Lee, 20 vol. (1910); the Tudor Edition, by W. A. Neilson and A. H. Thorndike, 39 vol. (1911–13); the Nonesuch Edition, by H. Farjeon, 7 vol. (1929–33; reprinted in 4 vol., with new introduction by Ivor Brown, 1953); the New Temple Shakespeare, ed. by M. R. Ridley, 40 vol. (1934–36); *The London Shakespeare*, ed. by J. J. Munro (1957). One-volume editions include *The Players' Shakespeare*, ed. by H. Granville-Barker (1923); and the editions by G. L. Kittredge (1936), and C. J. Sisson (1955). There are editions of the poems by G. Wyndham (1898), and H. E. Rollins (1938; the New Variorum edition); of the poems and songs by Edward Hubler (1959); and of the sonnets by E. Dowden (1881), R. M. Alden (1916), T. G. Tucker (1924), and F. T. Prince (1960; Arden). Ascribed plays are in *The Shakespeare Apocrypha* (1908), ed. by C. F. T. Brooke. *Sir Thomas More* was ed. by F. J. Shirley (1938) and by H. Jenkins (1954); *Arden of Feversham* by H. Macdonald, for the Malone Society (1947).

Life, Personality, Interests, etc.: General: The standard scholarly life, including documents and bibliographical introductions to each chapter, is still Sir E. K. Chambers, *William Shakespeare: a Study of Facts and Problems*, 2 vol. (1930), supplemented by his *Shakespearean Gleanings* (1944), and *Sources for a Biography of Shakespeare* (1946). Earlier lives still of value are J. O. Halliwell-Phillipps, *Outlines of the Life of Shakespeare* (1881; 7th rev. ed. 1887); Sir S. Lee, *A Life of William Shakespeare* (1898; 14th ed. 1929); Sir Walter Raleigh, *Shakespeare*, "English Men of Letters" Series (1907). J. Q. Adams, *A Life of William Shakespeare* (1923); C. F. T. Brooke, *Shakespeare of Stratford* (1926); L. Hotson, *Shakespeare Versus Shallow* (1931), *I, William Shakespeare, do Appoint Thomas Russell, Esquire, . . .* (1937); J. Dover Wilson, *The Essential Shakespeare* (1932); G. B. Harrison, *Shakespeare at Work, 1592–1603* (1933); E. I. Fripp, *Shakespeare, Man and Artist*, 2 vol. (1938; new ed. 1964); P. Alexander, *Shakespeare's Life and Art* (1939), *Shakespeare* (1964); Ivor Brown, *Shakespeare* (1949), *How Shakespeare Spent the Day* (1964); M. M. Reese, *Shakespeare: his World and his Work* (1953); F. E. Halliday, *The Life of Shakespeare* (1961); G. E. Bentley, *Shakespeare: a Biographical Handbook* (1961); A. L. SHAKHTY (formerly ALEXSANDROV-GRUSHEVSKI), a town in Rostov Oblast' of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the upper Grushevka (a small stream flowing by way of the Tuzlov into the Don), 40 mi. (64 km.) NE of Rostov-na-Donu (Rostov-on-Don). Pop. (1959) 196,190. As its name ("Pits") implies, the town is engaged in coal mining. It is the main centre of the eastern end of the Donets Basin (Donbass), with about 30 pits in the immediate vicinity of the town. The coal is of high quality and anthracite forms about 85% of the production. Coking coal is also found. Other industries include iron casting, canning, brewing, and the manufacture of footwear and clothing. There is a coal-burning power station. In its southern suburb of Kamenolomni there are stone quarries and metal works. The main lines of communication for Shakhty are the railway and highway from Rostov to the Donbass. Shakhty has a pedagogic institute and technical schools for coal mining. (R. A. F.)

SHAKTISM (ŚAKTISM), an ensemble of Indian philosophical systems and religious cults which consider the divinity as Supreme Power or Energy, personified as the Mother Goddess. Together with Vishnuism and Shivaism (*qq.v.*), it is one of the main forms of modern Hinduism, especially popular in northeast India, particularly Bengal and Assam. Shakti (Śakti) is conceived either as the sovereign deity or as the consort of a male deity, generally Shiva. Indian speculation regards the male principle as quiescent (transcendence being understood as repose) and the female principle as active and creative; both are complementary aspects of the ultimate monism. This conception of Shiva and Shakti further coalesced with the Sankhya idea of *purusha-prakriti* and with the popular Vedantic idea of Brahma-*maya* (for these, *see* INDIAN PHILOSOPHY: *Sankhya* and *Vedanta*).

Spiritually minded men worship Shakti as the Divine Will, the Divine Mother who calls for absolute surrender. Yogis consider this Shakti as the power, lying dormant within the body as a coiled serpent, which must be aroused and realized to reach liberation. Shaktism is inseparably related to Tantrism (*q.v.*), a system of practices for the purification of both mind and body. In popular worship the goddess has many names, standing for the forms in which she has appeared in the world. Thus she is worshiped as Durga, with both terrifying and gracious aspects; as the four-armed destroyer of Kali; as the gracious Lakshmi and Sarasvati, consorts of Vishnu; as Shashthi, protector of children; and as Shitala, the personification of smallpox. *See* also HINDUISM: *Gods*.

See Sri Aurobindo, *The Mother* (1928, often reprinted); Sir John Woodroffe, *Shakti and Shakta* (1951). (S. B. D. G.)

SHALE is a fine-grained, earthy sedimentary rock that is a somewhat indurated clay and is characterized by a thinly layered or laminated structure, by which it is differentiated from clay. It is usually harder than clay and has less tendency to slake in water. It is usually gray, yellow, green, or red.

Shales are sediments that accumulated in past geologic time in lakes, lagoons, oceans, etc. Their properties and composition depend upon the character of those sediments; the uniformity of the source material from day to day and from year to year; variations within the area of accumulation; and changes that took place during and after its deposition in the area of accumulation (*see* SEDIMENTARY ROCKS).

Some shales contain components other than clay minerals (*see* CLAY AND CLAY MINERALS), and varietal names are given on this basis; *e.g.*, sandy shale, limy shale, bituminous shale, etc. Shales find extended use in the manufacture of structural clay products, such as brick, tile, and portland cement. *See* also FUELS: *Carbonisation;* and references under "Shale" in the Index. (R. E. GM.)

SHALE, OIL: *see* FUELS: *Carbonization.*

SHALLOT, a hardy onionlike perennial (*Allium ascalonicum*), of the lily family (Liliaceae), with small, elongated, somewhat angular bulbs that develop in clusters on a common base. The leaves are short, small, cylindrical, and hollow. The flowers of the compact umbel are lilac or reddish in colour. The shallot is probably of Asiatic origin. The common so-called shallot that is marketed extensively as green spring onions is in fact a form of the onion. (V. R. B.)

SHALMANESER (Assyrian SHULMANU-ASHARIDU, "the god Shulman is chief"), the name of five Assyrian kings. Of the reigns of Shalmaneser II (1030–19 or, perhaps 1019–08 B.C.) and Shalmaneser IV (782–772 B.C.) little is known.

SHALMANESER I, son of Adad-nirari I, ruled 1275–45 B.C. While the Hittites warred with Egypt, the Assyrians invaded Cappadocia (in eastern Asia Minor) and founded an Assyrian colony at Luha. By the defeat of Shattuara of Hani and his Hittite allies and by raids on Carchemish, Irridi, and the Kashiari Hills (all in the region around the borders of northern Iraq, northeastern Syria, and southeastern Turkey), Shalmaneser reopened the main northwestern trade routes. At his capital, Ashur, he built a palace and restored one of the temples. His buildings at Nineveh and at Kalakh (or Kalhu; modern Nimrud), the latter of which he

founded, have been partially recovered.

SHALMANESER III, son of Ashurnasirpal II, reigned 859–824 B.C. His vigorous policy of military expansion was opposed on all frontiers. Babylonia was quiet except for a rebellion by the usurper Marduk-bel-usate which was quashed in 851 B.C. On the eastern frontiers (near the borders of northeastern Iraq and northwestern Iran), the rulers of Musasir, Namri, Zamua, and Kirhi were made vassals and Parsua was raided. Although Shalmaneser twice led his army as far as Lakes Van and Urmia and campaigned in Tabal and Cappadocia (836 B.C.), Sardur (Sarduris) I of Urartu remained undefeated. The main military effort was devoted to the conquest of North Syria. Ahuni of Bit-Adini was captured only after four campaigns, and progress farther west was barred by a coalition led by Irhuleni of Hamath and Bar-Hadad I (Hebrew, Ben-Hadad; throne name, Hadadezer; Akkadian, Adad-idri) of Damascus. In 853 B.C. Shalmaneser fought these allies, whose forces numbered 63,000 infantry, 2,000 cavalry, 4,000 chariots, and 1,000 camels. Of these, 10,000 men and half the chariots were provided by Ahab (Ahabbu) of Israel according to the first reference to Israelites in the Assyrian annals. This battle, at Karkar, was indecisive and, apart from two skirmishes, Shalmaneser did not appear in the west until the coalition had broken up.

In 841 B.C. he defeated Hazael and, failing to capture Damascus itself, marched to the Mediterranean coast where he received tribute from Tyre, Sidon, and Samaria. The submission of the latter is shown on the "Black Obelisk" (from Nimrud, now in the British Museum) where "Jehu, son of Omri" bows before Shalmaneser. By 832 Cilicia had been invaded, Tarsus captured, and the region made an Assyrian dependency. The remaining campaigns of Shalmaneser's reign were led by the army commander against Sardur I and the Mannai. Before the king died in 824 B.C. civil war broke out between a son, Ashur-danin-apal, and his heir, Shamshi-Adad V. Shalmaneser rebuilt a palace and ziggurat at Nimrud. His wars were commemorated both on palace reliefs there and on the gates of the temple at Balawat.

SHALMANESER V reigned from 727 to 722 B.C. None of his historical records survive, but the King-List of Babylon, where he ruled as Ululai, links him with Tiglath-pileser III, whose son he may have been. When Hoshea of Israel rebelled (II Kings 17), he marched via Bit-Adini to besiege Samaria and attack Tyre. For three years he laid siege until "he broke the resistance of Shamara'in" (Samaria). However, he died in 722 B.C. before the capture of the city, which was claimed by his successor, Sargon II.

SHAMANISM is a religious phenomenon characteristic of Siberian and Ural-Altaic peoples. The word shaman itself is of Tungus origin (*saman*) and it has passed, by way of Russian, into European scientific terminology. But shamanism, although its most complete expression is found in the arctic and central Asian regions, must not be considered as limited to those countries. It is encountered, for example, in southeast Asia, Oceania and among many North American aboriginal tribes. A distinction is to be made, however, between the religions dominated by a shamanistic ideology and by shamanistic techniques (as is the case with Siberian and Indonesian religions) and those in which shamanism constitutes rather a secondary phenomenon.

The shaman is medicine man, priest and psychopompos; that is to say, he cures sicknesses, he directs the communal sacrifices and he escorts the souls of the dead to the other world. He is able to do all this by virtue of his techniques of ecstasy; *i.e.*, by his power to leave his body at will. In Siberia and in northeast Asia a person becomes shaman by hereditary transmission of the shamanistic profession or by spontaneous vocation or "election." More rarely a person can become shaman by his own decision or upon request of the clan, but the self-made shamans are regarded as weaker than those who inherit the profession or who are "elected" by the supernatural beings. In North America, on the other hand, the voluntary "quest" for the powers constitutes the principal method. No matter how the selection takes place, a shaman is recognized as such only after a series of initiatory trials after receiving instruction from qualified masters.

Asia.—In Asia as a rule the trials take place during an indefinite period of time in which the future shaman is sick and stays in his tent or wanders in the wilderness, behaving in such an eccentric way that it could be mistaken for madness. Several authors went so far as to explain arctic and Siberian shamanism as the ritualized expression of a psycho-mental disease, especially of arctic hysteria. But the "chosen" one becomes shaman only if he can interpret his pathological crisis as a religious experience and succeeds in curing himself. The serious crises that sometimes accompany the "election" of the future shaman are to be regarded as initiatory trials (*see* PASSAGE RITES). Every initiation involves the symbolic death and resurrection of the neophyte. In the dreams and hallucinations of the future shaman may be found the classical pattern of the initiation: he is tortured by demons, his body is cut in pieces, he descends to the netherworld or ascends to heaven and is finally resuscitated. That is to say, he acquires a new mode of being which allows him to have relations with the supernatural worlds. The shaman is now enabled to "see" the spirits, and he himself behaves like a spirit; he is able to leave his body and to travel in ecstasy in all cosmic regions. However, the ecstatic experience alone is not sufficient to make a shaman. The neophyte must be instructed by masters in the religious traditions of the tribe, and he is taught to recognize the various diseases and to cure them.

BY COURTESY OF THE ARCHIV DES MUSEUMS FÜR VÖLKERKUNDE, HAMBURG

SIBERIAN SHAMAN, EARLY 20TH CENTURY

Among certain Siberian peoples the consecration of the shaman is a public event. Among the Buryats, for example, the neophyte climbs a birch, a symbol of the world tree, and in doing this he is thought to ascend to heaven. The ascension to heaven is one of the specific characteristics of Siberian and central Asian shamanism. At the occasion of the horse sacrifice, the Altaic shaman ascends to heaven in ecstasy in order to offer to the celestial god the soul of the sacrificed horse. He realizes this ascension by climbing the birch trunk, which has nine notches, each symbolizing a specific heaven.

The most important function of the shaman is healing. Since sickness is thought of as a loss of the soul, the shaman has to find out first whether the soul of the sick man has strayed off far from the village or has been stolen by demons and is imprisoned in the other world. In the former case the healing is not too difficult: the shaman captures the soul and reintegrates it in the body of the sick person. In the latter case he has to descend to the nether world, and this is a complicated and dangerous enterprise. Equally stirring is the voyage of the shaman to the other world to escort the soul of the deceased to its new abode; the shaman narrates to those present all the vicissitudes of the voyage as it goes on.

Another type of descent is represented by the journey of the Eskimo shaman (*see* below) to the bottom of the ocean, to the Mother of the Seals; he undertakes this submarine voyage when the seals become scarce and the population is menaced by a famine.

As a rule the shaman has several auxiliary spirits at his disposal, but he is not possessed by them. The spirits help him to find the soul of the sick person, and sometimes they accompany

him in his ecstatic voyages. In certain regions the shaman ends by being really possessed by his auxiliary spirits, and he becomes their mouthpiece; but the possession is a secondary phenomenon found especially in those regions where shamanism is mingled with other magico-religious conceptions and techniques.

Shamanism represents the mystical experience characteristic of the primitive and archaic religions. The "flight" of the shaman to heaven can be regarded as the most ancient expression of mystical experience known to mankind. But the shaman is not only a mystic. He is just as much the guardian (and largely the creator) of the traditional lore of the tribe, he is the sage and even the poet of primitive societies. The narrations of his adventurous descents to the netherworld and of his ascents to heaven constitute the material of popular epic poetry in central Asia and in Polynesia.

Eskimo.—Shamanism predominates in the religious life of the Eskimos. The chief prerogatives of the Eskimo shaman (*angakok;* pl., *angákut*) are healing, the ecstatic underwater journey to the Mother of Animals for the purpose of assuring an abundance of game, and the aid he brings to barren women. Sickness is brought on by the violation of tabus or results from the capture of the soul by a ghost. In the first case, the shaman strives to drive out the impurity by collective confessions; in the second case, he undertakes the ecstatic journey to heaven or to the depths of the sea to retrieve the sick person's soul and restore it to his body. The *angakok* is also a specialist in magic flight. Some shamans are reputed to have visited the moon; others claim to have flown around the earth. The *angákut* also know the future, make prophecies, predict changes in the weather and excel at magic feats.

American Indians.—Among many North American tribes shamanism constitutes the most important aspect of the religious life. The shaman is characterized by the supernatural power he acquires as the result of a direct personal experience. This power is obtained either spontaneously or after a voluntary quest, but in either case the future shaman has to undergo certain initiatory trials. In general, the power is utilized in such a way as to affect the whole society. The shaman's principal function is healing, but he also plays an important role in other magico-religious rites such as, for example, communal hunting and, where they exist, secret societies (*see* SECRET SOCIETIES, PRIMITIVE) or mystical movements (Ghost Dance [*q.v.*] religion type). North American shamans, like all their fellows, claim to control the weather (bring on or stop the rain, etc.), know future events, expose the perpetrators of thefts, etc. Furthermore, they defend men against sorcerers. But the magico-medical powers held by North American shamans do not exhaust their ecstatic abilities. There is every reason to suppose that modern secret societies and mystical movements among the Indians have appropriated in large part the ecstatic activity that once characterized shamanism.

In the tribes of South America the shaman enjoys considerable prestige and authority. Not only is he the healer *par excellence* and, in certain regions, the guide of souls of the dead to their new abode; he is also the intermediary between men and the gods or spirits, substituting himself for the priest at times. He guarantees the respect for ritual observances, defends the tribe against evil spirits, points out places for fruitful hunting and fishing, increases the wild life, controls the weather, eases childbirth, reveals future events, etc. Of course, the South American shaman can also fill the role of sorcerer; he can, for example, change himself into an animal and drink the blood of his enemies. Yet it is rather to his ecstatic abilities that the South American shaman owes his magico-religious position and social authority.

It is probable that a certain form of shamanism was diffused on the two American continents with the first waves of immigrants from Asia; later contacts between northern Asia and North America made Asian influence possible well after the penetration of the first immigrants.

Africa.—Shamanism does not play a role of the first order in Africa.

Southeast Asia and Oceania.—Shamanism is prevalent in the Malay peninsula and in Oceania. Among the Negritos of the Malay peninsula, the shaman heals with the help of celestial spirits or by using crystals of quartz. But the influence of Indo-Malayan beliefs is noticeable, too (the shaman changing into a tiger, trance achieved by dancing, etc.). In the Andaman Islands, the shaman gets his power from contact with spirits. The commonest method is to "die" and return to life, the traditional pattern of shamanic initiation. The shamans gain their reputation through their acts of healing and their meteorological magic (they are thought to bring on storms).

The distinctive marks of Malayan shamanism are the calling forth of the tiger's spirit and the achievement of the trance (*lupa*), during which the spirits seize the shaman, possess him and reply to questions asked by the audience. Mediumship is also characteristic of different forms of shamanism in Sumatra, Borneo and Celebes. Among the Ngadju-Dayak of Borneo there even exists a special class of shamans, the *basirs* (literally, "incapable of procreation"), hermaphrodites who dress and act like women. These are considered to be intermediaries between heaven and earth because they unite in their own person the feminine element (earth) and the masculine element (heaven).

Possession by gods or spirits is a peculiarity of Polynesian ecstatic religion. The extreme frequency of possession in that region has made possible a proliferation of healers. Priests, inspired persons, medicine men and sorcerers may all perform magical cures. For this reason it is not possible to speak of shamanism *stricto sensu* in Polynesia.

In Australia, a person becomes a medicine man through a ritual of initiatory death, followed by a resurrection to a new and superhuman condition. But the initiatory death of the Australian medicine man, like that of the Siberian shaman, has two specific marks not found elsewhere in combination: first, a series of operations performed on the candidate's body (opening of the abdomen, renewal of the organs, washing and drying of the bones, insertion of magical substances); second, an ascent to heaven, sometimes followed by other ecstatic journeys into the other world. The revelations concerning the secret techniques of the medicine men are obtained in a trance, a dream or in the waking state before, during or after the initiatory ritual proper.

SHAMASH, the name of the sun-god of the Semitic pantheon. The Akkadian Semites (*c.* 2300 B.C.) identified their sun-god Shamash with the local Sumerian sun-god Utu, whose temple was called Ebabbar, and whose picture sign was a disk rising from two mountains in the east to indicate the rising sun. In processions of gods, Shamash is pictured seated on a horse, and in pre-Islamic Arabia the horse is a symbol of the sun. In the Old Testament it is said of King Josiah that "he removed the horses that the kings of Judah had dedicated to the sun, at the entrance to the house of the Lord . . . and he burned the chariots of the sun with fire" (II Kings 23:11).

The early chief attribute of the Sumerian god Utu was fruitfulness. But by about 2130 B.C., the ruler of Lagash, Gudea, is saying that "Utu causes Righteousness to come forth; as for Unrighteousness Utu treads its head underfoot." King Ur-Nammu, who established the 3rd dynasty of Ur (*c.* 2130 B.C.), and of whose Sumerian law code fragments have been found, speaks of the just laws of Utu. The last king of Isin (*c.* 1820 B.C.) dedicates to the Semitic Shamash a temple named "House of the Judge of the Land." In Akkadian Semitic thought, the sons of Shamash are Justice (*kettu*) and Right (*mesharu*). The code of Hammurabi, which is concerned precisely with these, is eloquent in praise of "the great judge of heaven and earth" to whom the king in the text attributes the laws. Before this god the king is shown standing in reverence on the relief which forms part of the stele on which the laws are inscribed.

The chief centres of the cult of the sun-god were at Zararim (Akkadian Larsa) in Sumer and at Sippar in Akkad. At the former city Ur-Nammu built a temple to Utu, but this is the only mention on the surviving tablets of a temple to this god, though there

is frequent mention of a shrine (*bara*) and of offerings to him. The Akkadian king Naramsin (*c.* 2230 B.C.) founded the temple, at Sippar, whose foundations Nabonidus, the last king of Babylon (556–539), claims to have discovered. Here the cult of the sun-god was revived after a long period of neglect. Inscriptions of Assyrian kings from the 16th century B.C. onward testify to his cult, and there were temples in his honour at Ashur and Nineveh, the ancient and later capitals.

Shamash ranked below Sin (*q.v.*), the moon god, whose son he was. With his father and his sister, Ishtar, he forms the secondary cosmic triad of the pantheon. Already among the Sumerians he was a warrior god, and later Akkadian sources represent him as conqueror of darkness in the heavens and on earth. To mortals he is the giver of light, the searcher of hearts, the source of laws of righteousness, the giver of life, protector of the oppressed and the terror of the wicked, whom his rays, like a net, catch and hold fast. Augurers have recourse to him, and oaths are sworn before him.

His consort was Aya, a Sumerian goddess, later absorbed by Ishtar.

SHAMIL (1798?–1871), the leader and unifier of the Muslim mountaineers of Dagestan and the Chechen country against the Russians. He was born at Gimry, the son of a free landlord. He studied grammar, logic, rhetoric, and Arabic and soon acquired the prestige of a learned man. In 1830, under Gazi Mohammed, the first elected imam of Dagestan, Shamil became one of the exponents of Muridism, a movement which demanded holy war against the Russians and the maintenance of the sacred law of the *Sheriat* against the *Adat* (a less orthodox interpretation of the Koran).

In 1832 Gazi Mohammed was killed by the Russians; two years later his successor Gamzat Bek was assassinated by his own supporters. Then, in 1834, Shamil was elected third imam of Dagestan. He conducted the war against the Russian invaders with personal courage and resourcefulness. His extermination of khans and beks who submitted to Russia, his liberation of their serfs, and, especially, his success in eluding capture made him a legendary hero. The struggle was so intense and passionate that the peasant peoples of northeastern Caucasia surmounted their tribal and linguistic particularisms and became united.

In 1859 the Russians decided to put an end to Shamil's rule. An army of 200,000, with 200 guns, under General A. I. Baryatinski started operations from all sides. Resistance was gradually overcome; and on Sept. 6 Shamil himself, besieged with a handful of Murids at Gunib, was taken prisoner. Incarcerated first in St. Petersburg, he was later sent to reside at Kaluga. In 1870 he made a pilgrimage to Mecca; he died, probably at Medina, in March 1871. His romantic fight had earned him a European reputation.

SHAMMAI, along with Hillel (*q.v.*) the leading Palestinian Jewish sage at the end of the last century B.C. and the early part of the 1st century A.D. In his time, on more than a few occasions, his views and those of his school (the House of Shammai) found readier acceptance in Pharisaic intellectual circles than they did later, after the Hillelite influence triumphed. But as late as the 2nd century, some talmudic scholars still reflected and favoured Shammaite tendencies, essentially conservative, adhering closely to earlier, transmitted teachings and strict in the application of legal injunctions. Shammai, like other Pharisaic and later rabbinic scholars, was no fundamentalist, and he engaged in biblical exegesis as well as development of the Oral Law; but his interpretations reveal a literalness of mind which contrasts sharply with the greater imaginativeness and plasticity encouraged by the Hillelite school. (*See* also TALMUD: *Oral Law: Shammaites and Hillelites.*)

To say seriously what Shammai was like as a person is impossible, for in most of the (few) narratives about him he is used by the storytellers as a foil, to highlight the virtues of Hillel. The effect is chiaroscuro, neither history nor biography. The stories were probably popular exempla of the late 1st and 2nd century intended for the amusement of audiences and the instruction of children. His few sayings and decisions, and the views of the school over which he presided, suggest that he was a product of the older and more conservative generation, that he regarded with suspicion compromises with tradition, that he was noteworthy for his impatience with verbosity or, despite his insistence that all men be received cheerfully, with strangers who made grotesque demands upon him. There is good reason to believe that he felt strong sympathy for those groups that encouraged revolt against the Roman authorities. (JU. G.)

SHAMROCK. According to an Irish legend, St. Patrick first chose the shamrock as a symbol of the trinity of the Christian church because of its three leaflets. With a shamrock he is said to have driven the snakes of Ireland into the sea. The name is applied to several plants of the pea family (Leguminosae), among them wood sorrel (*Oxalis acetosella*); white clover (*Trifolium repens*); suckling clover (*Trifolium dubium*); and black medic (*Medicago lupulina*). Wood sorrel is shipped from Ireland to London and other places in great quantity for St. Patrick's Day. For that holiday in the United States the plants most commonly used as shamrock are white clover and species of *Oxalis* (*q.v.*).

The shamrock pea is *Parochetus communis*, a creeping legume with bicoloured blue and pink flowers; it is used as a pot plant and for hanging baskets.

SHAN, the Burmese term for speakers of Thai (Tai) languages other than Siamese. Thai (Tai) principalities (*möng*) of varying size exist in Assam, Burma, Thailand, Laos, Vietnam, Cambodia, and throughout southwest China. In Burma the Shan numbered more than 1,250,000 in the 1960s (*see* THAI PEOPLES).

Although holding mainly high upland territory in Burma, the Shan themselves live only in the valleys and in stretches of plain. The surrounding hill country is occupied by relatively primitive hill peoples living in economic symbiosis with the Shan, but there is no clear genetic distinction between the Shan and their neighbours. With minor exceptions modern Shan communities are Buddhist. Most Shan are cultivators of rice; they have a characteristic species of feudal political structure. Shan culture probably diffused southward and westward from west-central China from Han times (*c.* 200 B.C.) onward.

In a Shan *möng* the power of the prince (*saohpa*, anglicized *tsawbwa*) is theoretically absolute but is really exercised by appointed ministers (*amat*). The prince has semidivine attributes and, unlike the commonality who are monogamous, is expected to maintain an extensive harem. In some areas he should marry a half-sister as chief wife. Emphasis on patrilineal descent is confined to the royal lineages. Rank status is hereditary but there is no rigid caste endogamy. Thai counterparts of the Shan are known locally by a great variety of names; *e.g.*, Ahom, Khamti, Pa-yi, Lu, and Lao. *See* also AHOM; PA-YI; SHAN LANGUAGE; SHAN STATE; and references under "Shan" in the Index.

SHANGHAI (SHANG-HAI), a commercial metropolis of China and one of the world's largest seaports, occupying an extraordinarily favourable geographical situation for both internal and external trade. Geographic conditions have concentrated China's foreign trade into a single gateway to a degree unparalleled in any other great country. One of the original treaty ports (opened by the Treaty of Nanking, 1842), it owed its phenomenal growth to Occidental commercial enterprise.

The magnificent natural waterways united in the drainage of the Yangtze river give to the port at its outlet to the Pacific a vast commercial hinterland producing a great range of commodities and a large consumer market of about 200,000,000 inhabitants. In addition, it serves as the master port for the lesser ports of the China coast from Fukien to Shantung province. Ex-

ternally, it is the nearest port to Japan, and it lies directly on the great shipping lane from San Francisco to Singapore. Locally, Shanghai occupies one apex of the delta land south of the Yangtze, containing 20,000 sq.mi. (51,800 sq.km.) with more than 40,000,000 people, of whom about 70% are farmers who supply the city with food and with cotton and silk for its industries.

Climatically, Shanghai has the monsoon characteristics common to most of the east coast region, with its concentration of high rainfall in the spring and summer. The annual average is 45 in. of precipitation. Weather variability is provided by the frequent cyclonic storms moving eastward along the Yangtze valley, especially in spring. Shanghai's latitude is almost as far south as that of New Orleans, so that summers are uncomfortably hot and humid. Summer temperatures are kept below 32° C (90° F) by rains for part of July and August, and they seldom rise above 37° C (98° F), but humidity averages 84% for this period. In winter humidity drops to about 30% and absolute minimum temperature to −10° C (13° F).

The Harbour.—Shanghai does not escape the problems besetting delta cities. It lies about 14 mi. (23 km.) above the mouth of the Whangpoo River (Huang-p'u Chiang), a small tributary of the Yangtze near its estuary. Daily, rising tide water from the Pacific shunts Yangtze River water up the Whangpoo. The slow current at this stage leads to rapid deposition of sediments. In early times this also resulted in the silting up of Soochow Creek (Wu-sung Chiang), which flows from Soochow into the Whangpoo. The Whangpoo during the mid-19th century scoured out a channel to the Yangtze estuary at least 15 ft. (5 m.) deep and was able to accommodate the sailing vessels of the time. This led the British to select Shanghai as one of the five treaty ports opened to trade as a result of their success in the war with China (1839–1842). The Whangpoo's initial advantages were rapidly reduced by further silting, however, and by 1905 the channel depth was only 10 ft., leading to gloomy forecasts of Shanghai's future as a port. The problem, however, was largely solved by the work of the Whangpoo Conservancy Board. Its vigorous harbour policy resulted in the development of a good shipway with a minimum depth of 24–26 ft. (7.3–7.9 m.) at the lowest tides and a high-water depth of 30–42 ft. (9.1–12.8 m.). Requiring much greater efforts were the main bars of the Yangtze itself at the so-called Fairy Flats (Shen T'an). Large ships could enter the river only at high tide and through the south channel, while tides and currents made the approach to Shanghai somewhat difficult. Neglect during World War II and after the Communists took over resulted in a less commodious and useful harbour in the mid-20th century than during the 1930s.

Port Communications.—Numerous canals, some navigable to 80-ton barges and steamboats, lead from the Whangpoo to the surrounding countryside. These include a 36-mi.-long (58 km.) canal for navigation and flood control from T'ai Hu, a large lake in the west, to the Whangpoo, constructed in 1958. Shanghai's two chief railroad connections are with Nanking in the northwest and Hangchow in the south, 193 mi. (311 km.) and 118 mi. (190 km.) distant respectively. Through these cities Shanghai has rail connections with the north and south China networks. The role of railroads in Shanghai's growth has been minor, and in the 1930s her two main rail lines carried only the moderate amount of 1,000,000 tons annually per mile. The withdrawal of most of China's shipping by the Nationalist government of China to Formosa in 1949 left water transport at Shanghai at a low ebb. From June 1949 to May 1950 the Nationalist blockade brought the relative shares in total freight of railways and watercraft of all kinds to an approximate ratio of 3.2 to 1. The heavy reliance that was put on carriage by rail contributed in part to the piling up of large quantities of cargo here as in other parts of the country in the late 1950s when there were transport bottlenecks. Although several hard-surfaced roads usable to motor transport lead from Shanghai to the hinterland, the high cost of motor transport resulted in a low volume of trucking from the port.

Port Development.—When the British first realized the port potentials of Shanghai during naval operations in the Anglo-Chinese war, Shanghai was a small unimportant walled city on the Whangpoo about a mile above its junction with the Soochow Creek. In 1843 the British settlement was established between the Soochow Creek and the Yang-ching Canal a short distance north of the walled city. Later this strip between the canal and the walls became the site of the French concession, while the American settlement (Hongkew) grew up on the northern side of the Soochow Creek. The American and British sectors were joined in 1863 to form the International settlement. The foreign zones were administered separately until World War II. The settlement area once was marshy paddy land often flooded, but through careful drainage and filling the area was converted to sites suitable for buildings. However, construction faced the difficulty of finding stable foundations, since the unconsolidated sand and silt was about 1,000 ft. deep. Uneven settling of large buildings made it dangerous to construct skyscrapers until the problem was solved for buildings up to about 20 stories by floating them on concrete rafts. Many of the canals and open sewers were culverted over, although some were used for small boat and barge navigation. Pontoon jetties anchored along the bank provided landing facilities. From the walled city down river on the left bank, and for a longer distance up and down the river on the right bank (an area known as Pootung or P'u-tung) there were in the 1930s less than 10 mi. of riverside shipping frontages with a minimum depth of 12 ft. The congestion at Shanghai was great. Subsequent work by the Chinese municipality, which was continued after 1937 by the Japanese, resulted in additional wharfage just below the Pootung sector of the waterfront. Postwar construction by the Communist regime includes the K'ai-p'ing wharf at Jih-hui Chiang, which for the first time provided railroad connection directly to a wharf, and the new wharf at Pei-p'iao begun in June 1956.

Trade.—Shortly after being opened to foreign commerce in the 18th century the port of Shanghai began to dominate China's trade and by the 1870s it was handling about 62% of the total. By 1920 this had dropped to 45% as northern ports developed. In the post-World War II period before the Nationalists took refuge on Formosa, Shanghai accounted for 75% of the imports and 60% of the exports of China. Its importance declined abruptly after 1949 because of the Nationalist blockade, and by the mid-1950s Shanghai was in second place after Tientsin which had become the leading port for Communist China. However, by

the 1960s, Shanghai's trade had rapidly and progressively increased.

The export of tea and silk and the import of opium and cotton textiles dominated the greater part of the trade period from 1850 to 1937. During the 20th century, however, especially during the 1920s and 1930s, imports of machinery, metals, and raw materials rose to account for more than 65% of the import trade. In exports, the position of raw silk and tea, although not the quantity, diminished sharply, while bulk commodities such as raw materials, vegetable oils, hides and skins, and some manufactured products became increasingly important. Tung oil and pig bristles were two important raw materials marketed predominantly through Shanghai. In 1939 the value of exports from Shanghai was about the equivalent of U.S. $126,000,000, while imports reached about $94,000,000. These figures, somewhat incomplete because of the abnormal war situation, give some idea of the trade volume. Wartime trade from 1941 to 1945 was greatly reduced and toward the end amounted to little. The 1946 figures for China's exports as a whole (and Shanghai handled about 60% of them) were very small absolutely and relatively to their prewar ratio to imports. Large quantities of imports were UNRRA and American aid materials. After 1949, mainland China's trade was predominantly with the Soviet Union and Communist-dominated countries. There was a marked decline in the importance of consumer goods and a corresponding increase in the import of capital goods. Machinery, metals, chemical raw materials, scientific instruments, drugs, and fibres, especially cotton, were leading imports. Food and raw materials continued to furnish the bulk of the exports, but manufactured goods and machinery were also of some importance.

The number of foreign ships visiting the port, not unexpectedly, has declined since the 1930s. While the People's Republic of China claimed in the late 1950s that Shanghai had regained its importance as a leading seaport, this was not borne out by observations of foreign travelers nor by official shipping statistics. It was reported in 1958 that Shanghai harbour handled a record volume of 2,220,000 tons of cargo, the highest in the history of the harbour. Hence, it is assumed that much of this pertained to domestic freight movements. However, the food crisis in China after 1960 caused about 5,000,000 tons of grain to be shipped from foreign countries, much of it imported through Shanghai.

Industry.—Shanghai not only is one of China's leading ports, but also a leading manufacturing city. Before 1937 it accounted for at least half of the country's large-scale Western-type industrial production. Of this industry, 40–50% of the value of output and 50–60% of the labour of the city was in textile manufacturing. This was led by cotton-spinning followed in order by silk-reeling, cotton weaving, wool spinning and wool weaving. Food industries came second with 30–35% of the value of production. Among these, flour milling and cigarette manufacturing were most important. Other industries in order of importance were leather goods, rubber goods, paper and publishing, chemicals, and machine manufacturing. While cotton and silk industries found their raw materials in Shanghai's immediate hinterland in the Yangtze delta, flour mills depended upon wheat shipped from abroad, while tobacco came from the north China plain. The metals- and rubber-using industries were farthest removed from their sources of supply. Shanghai's coal was imported from north China, Japan, and northern Vietnam prior to 1949. The Shanghai power company, using coal as fuel, produced 70% of the city's power, and as coal could be brought in by cheap ocean transportation the city's power rates were among the cheapest in the world. Industries developed along both banks of the Whangpoo except along the Bund (a waterfront thoroughfare), but the east bank was less important because of location factors.

Shanghai emerged from World War II in a precariously depressed condition. Most of the textile plants and spindles as well as other factories were destroyed or inoperative. Rehabilitation began gradually. In 1949 Shanghai metal industries turned out 5,000 tons of steel and about 13,000 tons of steel products. Following the initial take-over, the Communist industrial policy was to keep privately owned plants in operation with the government absorbing the output but at fixed prices. The second step was the formation of joint government-private companies which by the beginning of 1956 took in all industrial ventures. This smoothed the transition to full government ownership and operation, since the old managerial staffs were largely retained on a salary basis. Following the Nationalist air bombardment of February 1950, there was a temporary industrial exodus and a move to decentralize Shanghai's industries by removing them to the interior. In 1953 the city had only 20% of the total value of mainland China's industrial output, but this was officially claimed to be 368% higher than that of 1950.

In the mid-20th century Shanghai had about one third of China's cotton spindles and produced about 2,000,000 bales of cotton yarn. China's first rayon plant went into production in 1958. In 1950 the city's flour mills had 20% of China's flour-making capacity of approximately 140,000,000 bags per year. This was above the consumption requirements of Shanghai, so it was decided to move some of the plant equipment to wheat-growing areas in the interior. Rice-milling production, however, was insufficient and was increased by the construction of new mills.

Next to Tientsin, Shanghai in the 1960s was a chief centre of chemical industry in China. The largest chemical factory was the Yung-li plant which produces ammonium sulfate and pure soda. The Wu-ching fertilizer plant built in 1960 went into full operation in 1963 with a 100,000-ton capacity for producing ammonium sulfate. One of China's chief cement plants is at Chiang-nan. A new policy to build up Shanghai as a heavy-industry and machine-manufacturing centre was well underway in the 1960s. In 1958, the year of the "great leap," Shanghai claimed to have achieved its goal of 1,222,000 tons of steel, 1.4 times the production of 1957. Output was scheduled to be further increased in subsequent years. The heavy industry was also pledged to make steel manufacturing equipment for other parts of China, electric power generators, and tractors. Among the major plants built or enlarged during the first five-year plan (1953–58) were shipyards at Chiang-nan and Hu-tung, a steam turbine works, a boiler works, and a lathe plant. In 1964 a 6,000-ton ocean freighter was launched at the Chiang-nan shipyard. Eight steel rolling mills for making seamless tube, welded pipe, alloy steel, and sheet iron were also included in the plan. In 1964 the first tinplate workshop was completed at the steel mill, and cylindrical grinders were being produced. Heavy industrial development increased considerably in the 1950s but on the other hand there was a marked decline in light industry. In all, 168 industrial plants in 17 industries were enlarged and 43 new plants built between 1949 and 1960. By 1961 Shanghai was the main centre of much heavy machine industry in China, and of the production of precision lathes, paper, glass, plastics, and watches.

Population.—According to the Nationalist census bureau Shanghai's population was 4,630,385 in 1948. The distress in the rural areas following the Communist cooperative farm program grain collections, together with natural calamities, brought a rapid urban influx of peasants which by 1953 had boosted Shanghai's population to 6,204,417. Efforts were made to reduce this, by forcible evacuation to the country, but many of these deportees probably managed to drift back. In 1957 the population was estimated at 6,900,000. By the mid-1960s reports indicated that the Shanghai urban area had ten million inhabitants. Shanghai's natural population increase since 1949 was estimated at an average rate of 200,000 per year. In 1964 the rate of population increase at Shanghai was 1.7%, much lower than the 2.2% estimated for the country at large. The city's industrial labour force in the 1960s was more than 1,000,000. The male to female sex ratio of the population in the 1953 census was 123 to 100.

Social Change and Culture.—Shanghai's social character has greatly changed. In the 1930s there were between 30,000 and 60,000 foreign residents, but now few foreigners are to be seen. In a city known once as a centre of gangsterism and of beggars and prostitutes, it is claimed that now not a single night club exists. About 10,000 prostitutes were put into reformatories for labour reform and rehabilitation to Communist society. Gambling was banned along with prostitution, and the famous racecourse and

dog race stadium were converted into a recreation park and museum. Numerous regulations were applied to urban inhabitants of Shanghai after 1950 and individual movement about the city was greatly restricted. Under the so-called Democratic Reform movement, begun in December 1952, former independent labour leaders were liquidated, and labour organizations were disbanded. Wholesale arrests of suspected Nationalist sympathizers were made. That the regime's problems were not all solved was indicated by the drive in 1958 to eradicate theft, gambling, vagrancy, census evasions, delinquencies, political sabotage, and illegal capitalistic enterprises. Shanghai was charged in 1957 with having over 9,000 clandestine factories with more than 30,000 workers.

In conformity with the national policy of making office workers and officials do manual labour, thousands of cadres were reported to have been organized and sent to rural areas for work. The city is being used as a training centre for clerks, skilled labour, and technicians for the new plants being established in the interior regions. In 1964, for instance, 4,000 workers were sent from Shanghai to Lan-chou to aid the development of light industry. In spite of censorship and reorganization, Shanghai is a major publishing centre, and also maintains its position as a leading educational and cultural centre. It is the site of Futan and Tungchi universities, and there are several medical colleges, museums, and libraries. Institutes of Foreign Languages, Technology, Drama, Law, Finance and Economics, and Marine Products and the Shanghai Conservatory of Music are located there.

Municipal Administration.—Shanghai is located in, but is politically independent of, Kiangsu province. Shanghai municipality, along with Peking, is treated on a par with provinces. The Communist municipal government has a mayor, 11 elected deputy mayors, 44 members of a peoples' council, and a peoples' congress consisting of 737 delegates. The latter is a number equal to that of any provincial congress. The area of Shanghai in 1958 was 772 sq.mi. (1,999 sq.km.). When the Communists first took over in 1949, they went into such detail of organization that in each of Shanghai's 11,185 streets a street committee was set up whose work was divided into six departments: health, education and culture, defense and security, social welfare, conciliation, and relief. This was furthered by the establishment in 1951 of the Shanghai Peoples' Control Commission. The control function was most likely performed by the Discipline Inspection Committee already established in all the administrative units of Shanghai's municipal government. Moreover, the municipal peoples' court of Shanghai set up in 1949 was placed under the control of the local Military Control Committee, thus reducing the court to a combination of military and administrative tribunal. The close tie with the party organization is shown in the position of Jao Shu-shih, the first secretary of the East China Party Bureau and of the Shanghai Municipal Party Committee, who in 1950 was also political commissioner to the 3rd Field Army under Ch'en I.

SHANKARA (780–820), Indian philosopher, the leading exponent of Advaita Vedanta, nondualism, and author of commentaries on the Upanishads, the Bhagavad Gita, and the Brahma Sutra which are known for their profundity of spirit and subtlety of thought. Shankara attempts to build a spiritual view of life on rational foundations: by reasoning we find that the world is not self-maintaining and must have a cause which is transcendent to it. In spiritual experience we apprehend the reality of this Absolute Spirit, which is called Brahman (*see* BRAHMA AND BRAHMAN). The differences of knower, known, and knowledge disappear when the Supreme Reality is known.

The world does not exist of itself but is derived from and dependent on Brahman and so is less real than Brahman. It is not, however, an illusion. The individual self which feels, suffers, and is affected by the experiences of the world is a phenomenon while the truth is Brahman. To recognize the highest truth as Brahman is to attain release. Meditation, worship, ritual are intended for a lower class of aspirants, and *jnana* (wisdom, knowledge of God) is the path to be pursued by the higher class of aspirants who have no desire for earthly prosperity or heavenly joy. There are two kinds of release: *sadyo-mukti*, or instantaneous liberation, and *krama-mukti*, or gradual liberation. The former is the result of *jnana*, the latter of *upasana*, or worship and prayer. Shankara makes out that the identity with the Highest Self is not destruction of soul. It is the perfection of the soul which has no more specific cognition or objective knowledge. *See* also INDIAN PHILOSOPHY: *Vedanta*. (S. RA.)

SHANKLIN: *see* SANDOWN-SHANKLIN.

SHAN LANGUAGE. Shan is a language of the Tai linguistic group spoken in the Shan and Kayah states of northern Burma. It is a noninflecting, basically monosyllabic, tonal language bearing considerable phonological and grammatical resemblance to other Tai languages such as Lao and Siamese (Thai). Compared with these, Shan exhibits a simpler syllabic structure, but greater differences exist in lexicon. Long contact with the Burmese language has influenced Shan, which contains many Burmese loan words.

The Shan script was developed from the Burmese. The traditional writing system is inefficient and causes grave reading difficulties even to Shans. In particular, it lacks sufficient vowel symbols and does not mark tone. These deficiencies were remedied in a series of reforms culminating in that of 1955, and the modern Shan script is an excellent phonetically based writing system.

Dialectal differences exist within Shan, but these are relatively minor. Dialects to be grouped with Shan are spoken by some Tai peoples in southwest China (*e.g.*, the Tai Mao people) and on the borders of Assam (*e.g.*, the Khamti people). These groups employ scripts which, though generally similar to that of Shan, exhibit marked stylistic variations.

Within the Shan state some peoples, notably the Khu'n of the formerly autonomous Kengtung state, speak Tai dialects which must be grouped with those of north Thailand rather than with Shan. *See* SHAN; SHAN STATE.

SHANNON, CHARLES HASLEWOOD (1863–1937), English artist who was notable for his lithographs, was born at Quarrington, Lincolnshire, April 26, 1863, the son of a clergyman. He was apprenticed to a trade wood engraver, in whose workshop he presently met Charles Ricketts, with whom he lived and worked until Ricketts' death in 1931, although their last direct collaboration was the periodical *The Dial* (1889–97).

Shannon's earliest designs were for Harry Quilter's *Universal Review*; but in 1893 he and Ricketts produced *Daphnis and Chloë*, a book in which text, illustrations and paper of choice quality formed a unique harmony. The first designs savour of early Renaissance book illustration, but the lithographs undertaken by Shannon from 1889 to 1898 are more personal, austere, delicate, and full of a silvery chiaroscuro. Often their subject matter is of a recondite mythological character, but among them are valuable portraits such as those of Alphonse Legros, George Moore, and Lucien Pissarro. Shannon as a painter was influenced by Titian, Tintoretto and, in allegorical subjects such as the "Vanity and Sanctity" (Diploma gallery, Royal Academy, London), by G. F. Watts; but here again he produced notable portraits such as the "Miss Bruce, Sculptress" in the Luxembourg, Paris. He was elected associate of the Royal Academy in 1911, full member in 1921. Between 1904 and 1919 appeared 46 more lithographs, fuller in form and richer in chiaroscuro than before. Shannon died at Kew, Surrey, on March 18, 1937, after eight years' disablement following a fall. The Ricketts and Shannon collection of prints, famous for its careful and original selection, is now in the British Museum, London.

See E. B. George, *C. H. Shannon* (1924). (D. C. T. T.)

SHANNON, the longest river in the Republic of Ireland, rises in the northwest of County Cavan and flows for about 161 mi. (260 km.) in a southerly direction to enter the Atlantic Ocean

via a 70-mi.-long (113-km.) estuary below Limerick. It drains an area of 6,060 sq.mi. (15,700 sq.km.). As the main river draining the Irish Central Lowland it is surrounded by marshes and bogs for much of its course, and widens out at various points into lakes, many with numerous islands.

The Shannon source is generally considered to be the pools at the foot of Tiltinbane Mountain (1,881 ft. [573 m.]), in County Cavan, but it is fed by a number of mountain streams in this area. After a few miles it enters Lough Allen (164 ft. above sea level, 7 mi. long, and 1 to 3 mi. wide) and then flows south through a wide belt of marshes and water meadows, locally called callows. In dry years these provide excellent natural pastures for cattle but in wet years the river becomes what the poet Edmund Spenser called "the spacious Shenan spreading like a sea." It is crossed by a bridge at Leitrim and also at Carrick-on-Shannon (*q.v.*), above which it is joined by the Boyle from the west. From north of Carrick south to Roosky, it flows through a landscape dominated by drumlins (low glacial hills), interspersed with bogs and marshes. Both the main stream and its tributaries, the Mountean from the west and the Rinn from the east, broaden out into lakes, such as Boderg and Bofin, and smaller sheets of water. Around Roosky the drumlins disappear and the river flows through ground moraine country or meadows and bogs, and crossings are infrequent.

Near Termonbarry (9 mi. below Roosky), at Richmond Harbour, the river is joined by the Royal Canal, and at Lanesborough it enters Lough Ree (nearly 18 mi. long and 1 to 6 mi. wide) which separates Longford and Westmeath counties on the east from Roscommon. The River Inny joins the lake on the east. From Athlone, a mile south of Lough Ree and originally built on an esker (or gravel ridge), the barrier nature of the Shannon becomes even more marked. The bridge at Athlone is 15 mi. from the next at Shannonbridge, though there is one ford at Clonmacnoise (*q.v.*). The Suck, the largest tributary, joins the Shannon at Shannonbridge and 2 mi. north of Banagher, at Shannon Harbour, the river is joined by the Grand Canal. About 15 mi. south it reaches Lough Derg at Portumna. This lake extends for over 20 mi. south to Killaloe, and in one section is 10 mi. broad. All of its waters are now dammed for the headrace, in effect a canal 7½ mi. long which feeds the Ardnacrusha hydroelectric station (1925–29). This uses the fall of 109 ft. from the lake to the sea level near Limerick, and concentrates it in one spot. The tailrace connects Ardnacrusha with the Shannon riverbed. Though power is generated, the river has proved less reliable than was first hoped owing to its fluctuations in level. A fish ladder has been constructed at the weir at the outlet of Lough Derg to allow salmon to pass up river at spawning time. From Limerick the river enters its long estuary where shipping has dwindled since the 19th century and where some of the large reclaimed areas have been used for the Shannon airport, located near the estuary of the Fergus River in County Clare.

In the middle reaches the Shannon divides the provinces of Leinster and Connaught and for most of its length it is a county boundary with contrasting landscape and land use on either bank. Clare and Galway on the west are poorer counties (with smaller farms) than Limerick and Tipperary on the east (though Leitrim in the north is an exception, being one of the poorest counties in Ireland). One reason for the economic divide is the lack of east-west communications.

In the early part of the 19th century the Shannon was a vital link in the waterways of the country, though before the days of steam transport navigation was difficult. From 1755 the Grand Canal was built from Dublin across the Central Lowland (though the Shannon was reached only in 1804) and until the coming of the railways was an important means of communication. From 1789 to 1817 the Royal Canal was constructed from the north side of Dublin through Mullingar to the Shannon at Richmond Harbour but, running through sparsely populated country, was never as successful as the Grand Canal and in 1846 was sold to the new railway company. At this period steamers used the Shannon between Killaloe and Richmond Harbour, and horsedrawn boats used the canal from Killaloe to Limerick. There were passenger services along the canals from 1780 but the canal services ceased in the 1850s because of railway competition. The Shannon steamboats survived until the coming of the automobile and were a tourist attraction until World War I. Since the 1950s a steamer service has been provided as a holiday attraction. (*See* also the separate articles on the counties mentioned above.)

See N. T. H. Delany, "The development of the river Shannon navigation," *J. Transport Hist.*, vol. 3, no. 4 (1958); T. W. Freeman, *Ireland: a General and Regional Geography*, 3rd ed. (1965).

(T. W. Fr.)

SHANSI (Shan-hsi Sheng), a province of north China, pop. (1957 est.) 15,960,000, occupies part of the loess plateau and is bounded by the Yellow River in the west and south, the Great Wall in the north, and Wu-t'ai and T'ai-hang mountains in the east where they drop off toward the North China plain. Area 60,656 sq.mi. (157,099 sq.km.). A northeast-southwest series of river basins and valleys roughly divides the eastern plateau from the western plateau into nearly equal halves. The Wu-t'ai and T'ai-hang ranges rise above the general 5,000–6,500 ft. levels and reach 9,974 ft. (3,040 m.) in a Wu-t'ai peak. In the west the Lu-liang is the chief range of the dissected plateau and reaches a peak elevation of 9,186 ft. (2,800 m.). Most of the valley land ranges between 2,300–2,600 ft., but southwest of An-i drops to below 1,300 ft. (400 m.). In the north, tributaries of the Yung-ting and Hai Ho have created the Ta-t'ung and Hsin Hsien basins, the latter dividing the Wu-t'ai from the T'ai-hang range. Southward lies the T'ai-yuan Basin and provincial seat on the upper Fen River, which runs thence southward and again widens into the lower Fen plain ending at the great lower bend of the Yellow River. The dry climate exhibits a decrease in precipitation from southeast to northwest, from 20 in. (510 mm.) to less than 10 in. yearly, much of the unreliable fall occurring in July and August.

A severe drought in 1957, resulting in a drop in production of 883,000 short tons of grain, was typical of the farming hazards. The growing season ranges from 150 days in the north to 250 days in the south. The rivers, which provide intermittent navigation in summer to flat-bottomed junks, are frozen as well as much constricted in winter. Millets, spring wheat in the north and winter wheat in the south, kaoliang, and corn are the chief crops. Some potatoes and oats are grown. Industrial crops include cotton, tobacco, hemp, and peanuts, and there are fruits such as the pear, apricot, persimmon, and grape, as well as walnut and the jujube date.

Animal husbandry is an important sideline, especially for the hill farmers, who raise chickens, sheep, pigs, horses, and donkeys and produce large quantities of eggs, wool, sheepskins, and pig bristles. The fertile but easily eroded loess soil blankets most of the hill slopes and permits extensive dry-terrace cultivation. The agricultural heart of the province lies in the Fen Valley which is part of the cotton belt that extends southwest into the Wei Valley of adjoining Shensi Province. The landscape generally is barren of trees except in the higher mountains, where over scattered areas forest covers an estimated 10,000,000 mou (1,500,000 ac.). Another 60,000,000 mou were reported suitable for afforestation.

Shansi has numerous scattered iron ore deposits, copper ores in the An-i region in the southwest, where one of China's salt sources also is found in Chieh-chih Lake (600,000-ton annual yield), and zinc and silver deposits in the north near Ta-t'ung. However, the province is most noted for being China's richest coal region, with about 47% of China's total coal or an estimated 400,000,000,000 tons, including coking and anthracite coals. The Ta-t'ung deposits lead among the six major fields in the province. Production is not as proportionately large. The more important iron mines are near Ch'ang-chih in the southeast, and at Yang-ch'uan, about 100 km. E of T'ai-yuan. Railroad communications connect T'ai-yuan with Ta-t'ung and Kalgan in the north, Shih-men in Hopeh Province in the east, and the Yellow River bend in the south. Ta-t'ung has rail connections with the industrial centre at Pao-t'ou in Inner Mongolia, and itself is the second most important industrial centre in Shansi, producing cement, locomotives, and mining machinery as well as coal. T'ai-yuan is the leading industrial centre (pop. [1957 est.] 1,021,000) and has one of the largest steel plants

China, as well as numerous chemical, machine, and iron smelting plants. Of the newer steel plants the largest is the Hsiang-feng, approximately equaling the T'ai-yuan plant in capacity. A phosphorus fertilizer plant with an annual capacity of 100,000 tons was completed in 1957. A high-voltage power line carries power to Yang-ch'uan along the railway eastward, while another line strung in 1957 carries high-voltage power to Fen-hsi in the Fen Valley to the south. Highway connections are poor and limited, but a major highway leads from T'ai-yuan to Ta-t'ung in the north, and other roads connect the Fen Valley with Ch'ang-chih in the east and the Yellow River in the west.

The provincial area has been part of the earliest heartland of Chinese civilization and was part of the state of Chin under the Chou dynasty. Its name originated during the Yüan period. From 1911 to 1949 it was governed for the most part by Yen Hsi-shan. Between 1937 and 1945 the Japanese occupied parts of the province, while Communist guerrillas harassed the Japanese from the T'ai-hang hills. (H. J. Ws.)

SHAN STATE in the Union of Burma consists of a group of formerly semi-independent states on the eastern frontier, which were formed into an administrative unit under the constitution of independent Burma introduced on Jan. 4, 1948. Pop. (1962 est.) 1,972,924. The group comprised the Shan states, inhabited by the Shan or Thai and other races, which in 1941 had a population of 1,699,000 and an area of 57,816 sq.mi. (149,744 sq.km.), and also the Wa states, with a population in 1941 of 82,614. Before Burma became independent the Shan states were governed by their hereditary chiefs, called sawbwas by the Burmese, under the control of the governor of Burma, but in 1922 they were federated for certain common purposes. Under the constitution of independent Burma the Shan State has a minister of the Burmese government at its head, aided by a state council comprising all the members of the Burmese Parliament representing the area; these members are elected by universal adult suffrage in the case of the lower house of Parliament and by the sawbwas in the case of the upper house. The state was given governmental authority in matters of agriculture, fisheries, public works, communications, police, administration of justice, education, public health, and local government, thus enjoying powers similar to those of a county council in the United Kingdom. The sawbwas retained their former administrative and judicial powers, subject to the minister and state council, until in October 1952 they were induced by the government to surrender their authority, retaining only their right to elect to the upper house of Parliament.

The Shan State is divided into three administrative areas, Southern, Northern, and Eastern, each under the charge of a resident, but the original states survive as minor administrative units. Taunggyi, 100 mi. (161 km.) SE of Mandalay, is the administrative centre of the state and the meeting place of the state council. Most other towns of the state are really large villages, formerly state capitals and now minor administrative centres, though they become very much alive on the periodic market days.

The former autonomous states are now mainly of historic interest. The 25 in the southern group ranged from Mong Nai (3,152 sq.mi. [8,164 sq.km.]) and Mong Pan (2,988 sq.mi. [7,739 sq.km.]) down to Kyong with a mere 24 sq.mi. (62 sq.km.) The northern group included the large states of North Hsenwi (capital Hsenwi), South Hsenwi (capital Mong Yai), and Hsipaw, or Thibaw, with considerable stretches of cultivated plain. The eastern group, east of the Salween River, includes Keng Tung (the capital Keng Tung can be reached by road east from Taunggyi but only in favourable weather), Manglun, Kokang, and the Wa country. The Wa are the most primitive of the peoples of the Shan State and until recently regarded headhunting as essential in their fertility rites, at plowing time, when rows of skulls were placed in avenues near villages. The Wa area is still only loosely administered.

Physical Features.—The Shan State borders Burma proper on the west, China on the north and east, Laos on the southeast, and Thailand on the south. The shape of the state is roughly that of a triangle, with its base near the plains of Burma and its apex on the Mekong River. The Shan Plateau is properly only the country between the deep trench of the Salween and the steep edge overlooking the Upper Irrawaddy and Sittang rivers. The average height of the plateau is between 2,500 and 4,000 ft. (750–1,200 m.), but it is seamed and ribbed by mountain ranges, which split up and run into one another. On the north the Shan State is barred by ranges following the line of the Myitnge River (Namtu). The huge mass of Loi Leng, 6,146 ft. (1,873 m.), projects south from this, and from each side of it and to the south is the wide plain extending to Mong Nai. The highest peaks are in the north and the south. Loi Leng is the highest point west of the Salween and in Kokang and other parts of North Hsenwi there are many peaks above 7,000 ft. (2,135 m.). The majority of the intermediate parallel ranges have an average height of between 4,000 and 5,000 ft. with peaks rising to over 6,000 ft. The country beyond the Salween is a mass of broken hills, ranging in the south from 2,000 to 3,000 ft., while in the north toward the Wa states they average from 5,000 to 7,000 ft. From December to March it is cool everywhere, and over five degrees (C) of frost is experienced on the open downs. The hot season temperature is 27 to 30° C (80–90° F), rising to about 38° C (100° F) in the Salween Valley. The annual rainfall varies from 60 in. (1,500 mm.) in the broader valleys to 100 in. (2,500 mm.) on the higher mountains.

The hill ranges rising from the plateau are usually forested. On the margins with Burma proper are important forest reserves with much teak but the Shan forests are best described as mountain forests dominated by evergreen oaks and, more locally, by pines such as *Pinus khasya*. The plains and valleys have much grassland and so, with their rolling character, are aptly described as downs. Over very large areas shifting cultivation is practised to the detriment of the forests; settled cultivation with rice is carried on when adequate water is available. Elsewhere cultivation with cereals including wheat and vegetables is limited to a few of the most fertile tracts.

Race and Language.—Shan State contains about two-thirds of all the Shans in Burma. The Thai or Tai, as they call themselves, were first known to the Burmese as Taroks or Tarets. The original home of the Thai people was China. Their first settlement in Burma proper was probably in the Shweli Valley, and from this centre they radiated at a comparatively recent date north, west, and southeast, through Upper Burma into Assam and into Thailand and Indochina. It is supposed that the group includes not only the Shans proper, the Laos, and the Thais or Siamese, but also the Muongs of Vietnam, the Hakkas of south China, and the Li, the inhabitants of the interior of the far eastern island of Hainan.

The Thai language may be divided into two subgroups, the north and the south. The south includes Siamese, Lao, Lu, and Hkun; the north, the three forms of Shan, namely North-Burmese Shan, South-Burmese Shan, and Chinese Shan with Hkamti and Ahom. The vernacular of the people who are known in Burma as Shan is South-Burmese Shan. This language is isolating and polytonic. It possesses five tones.

The Economy.—The Shans are a peaceful race, fond of trading. During the 20th century the trade with Burma increased considerably, especially after the construction of the Lashio (1903) and Shwenyaung (1928) railways. The huge silver-lead-zinc mines of the former Burma Corporation Ltd. are at Bawdwin in the northern part of the Shan State. Production declined for a time because of destruction suffered during the Japanese invasion and the frequent disruption of road and rail communications in the civil disturbances which often prevailed in Burma from 1948 on. The cultivation of wheat and potatoes in the southern areas for export to Burma proper is normally profitable but similarly suffered from interrupted communications.

Two railways penetrate into Shan State from the main Rangoon-Mandalay line. One from Thazi junction climbs the western edge of the plateau to the hill station of Kalaw, and across an extensive plain north of the large shallow Inle Lake (famed for its leg-rowers) to Heho and Shwenyaung at the foot of the ridge on which stands Taunggyi the capital. Farther north a branch line from near Mandalay climbs the scarp by a very scenic route

through Maymyo (*q.v.*) across a deep limestone gorge by the famed Gokteik viaduct to Lashio, chief town of the north. A narrow-gauge branch line runs to the Bawdwin mines through the smelting town of Namtu. Motorable roads follow along these two railways and extend eastward: through Taunggyi almost to the eastern limit of the state, with a ferry across the Salween River; from Lashio the famous Burma Road (*q.v.*) extends into China. There are also north-south roads, notably from Bhamo through Lashio and so southward to Loi-lem and the Thai border. Air services offer ready communication with Rangoon.

(B. R. P.; L. D. S.)

SHANTUNG (SHAN-TUNG SHENG), a densely populated coastal province of China between the Yellow Sea and the Gulf of Chihli, is bounded by Hopeh in the north, Honan in the west, and Kiangsu and Anhwei in the south. Area 59,189 sq.mi. (153,300 sq.km.); pop. (1957 est.) 54,030,000.

In early geological times its inland and peninsular hill masses comprised at least two large islands, while an inland sea or strait stood between them and the T'ai-hang hills of Shansi. Heavy sedimentation from the Yellow and Huai rivers filled this in to form the low-lying Yellow plain around the central hill mass. The province thus forms three physiographic regions: (1) the central hills, a triangular mass culminating in T'ai Shan (Mt. T'ai), elevation 5,069 ft. (1,545 m.); most of the hill lands rise to only about 1,300 ft., but several peaks reach over 3,200 ft. (2) The peninsular hills, with most elevations around 600 ft., but rising to 3,839 ft. (1,170 m.) in the Lao Shan northeast of Chiao-chou Bay and Tsingtao city. A submarine ridge connecting Shantung with Liaotung protrudes above the sea as the Ch'ang-shan archipelago. The islands and the indented peninsula favoured the development of sheltered harbours for fishing and commerce. (3) The plain which from the west slopes eastward to a northwest-southeast oriented trough at the western base of the central hills, and which in the north and south continues to the sea in the alluvial deposits of the Yellow River. The trough is occupied by several elongated lakes utilized in part by the Grand Canal cutting through western Shantung. The Yellow River in its present course flows past the northern foothills. Between the central hills and the peninsular hills is the corridor plain formed by sediments of the Pei-chiao and Wei rivers, over 62 mi. (100 km.) long and from 18 to 30 mi. wide.

History.—Western Shantung formed the easternmost parts of the earliest known organized state of China, the Shang (1520–1030 B.C.). Even earlier, an indigenous culture had developed there, as shown by a unique type of polished black pottery excavated at Ch'eng-tzu-yai. Southern Shantung as the state of Lu gave birth to Confucius and Mencius, honoured by a temple on T'ai Shan. The Lu kingdom, together with the Ch'i kingdom in northern Shantung, formed parts of the feudal domains of the Chou dynasty which lasted until the 3rd century B.C. Thus Shantung has from the beginning been part of the core area of the Chinese state. In more recent history Shantung symbolized China's humiliation by Japan and by European powers. It was occupied by Japanese forces during the Chinese-Japanese War of 1894–95. In 1898 Germany forced a lease of Tsingtao from which to exploit the province, while Great Britain similarly obtained a lease of Wei-hai for a naval base. The Boxer Rebellion developed out of Chinese resentment against foreigners in Shantung in 1899 and spread to other provinces in 1900. After World War I Japan tried to take over the German sphere of interest in Shantung and garrisoned troops there off and on between 1915 and 1929. When Japan attacked China in 1937, it was at T'ai-erh-chuang in southern Shantung that China won its first major victory over Japanese troops. In the Nationalist campaign against the Communists after World War II, the Communists were able to hold most of the province, and gained their first decisive victory in east China with the capture of the provincial capital of Tsinan in September 1948.

Climate and Agriculture.—In climate the peninsula is more moderate than the inland mass which shares the continental dryness and severity of north China winters. The northern part of the province is especially exposed to the northwest winds from Mongolia, but these winds pick up some moisture from the Gulf of Chihli and deposit some snow and rain on Shantung. The harbours freeze over at Chefoo and Lung-k'ou, and the January average for Chefoo is −4° C (24° F) while at Tsingtao it is 0° C (32° F). In summer when the inland plains have 35° C (95° F) temperatures, Tsingtao and Wei-hai only reach about 25° C (77° F). The precipitation has the usual summer peak, with south-facing slopes of the hill masses receiving over 30 in. (760 mm.) and the interior plains only about 20 in. (500 mm.). Some 1,200,000 wells (1951 estimate) provided the water for 85% of the land that is irrigated, although river water also is used. Expanded irrigation projects in 1956 provided water for some 17,930,000 mou (about 2,720,000 ac.) of additional irrigated land. The aggregate grain production (largely wheat, kaoliang, millets, and corn) increased greatly after 1949. Other crops include cotton, tobacco, and peanuts. Hogs are raised in large number.

The hills are capable of growing forests, but have been denuded during past centuries. Forests were being restored through afforestation in the second half of the 20th century, however, and along the coasts sand drift was being reduced by sand-fixing plants and trees. The convergence of warm and cool currents in the sea off Shantung is conducive to fish production. Tsingtao and Chefoo are the leading fishing centres.

Communications and Industry.—Communication facilities in the mid-20th century included more than 5,650 mi. (9,100 km.) of highways connecting all the 104 hsien (districts) of the province, but only about 930 mi. (1,500 km.) were all-weather roads. One major railroad runs from Tsingtao westward to Tsinan, the provincial seat, where it meets the north-south line from Tientsin to P'u-k'ou on the Yang-tzu. A rail line also leads from Tsingtao, the chief port, to Chefoo which is an embarkation port for travelers to Manchuria. Spur lines lead to the coal mining centres of Tzu-pu, Hsin-t'ai, and Tsao-chuang in the north-central, central, and southern hill areas respectively. The mining development at Tsao-chuang is one of the largest and most mechanized in China. There are numerous gold mines in the peninsular hills, the most important being in Chao-yuan district. The more noted iron ore mines are at Chin-tien-chen and Li-kuo-i, and important aluminum ore mines are at Nan-ting. The coastal salt industry is centred at Chiao Hsien.

Important industries of the province include cotton textiles, cigarette and match making, flour milling and oil pressing, brewing and distilling, machinery and chemicals; about 90% of the country's peanut oil was produced there in the mid-20th century.

(H. J. Ws.)

SHANTY (sometimes spelled CHANTY, a reflection of its putative derivation from the French *chanter*, "to sing"), in folk music, is a work song, usually of leader-chorus pattern. A group engages in a collective task, such as canoe paddling, net hauling, making sail, capstan turning, laying railway tracks, and road building. The group leader intones a line of song, and the group responds in chorus, usually singing a fixed refrain, heaving at a given point in the melody. Then follows another solo phrase, and again the concerted refrain-and-heave. By means of verbal improvisation and repetition, the shanty may be spun out for as long as the task endures; thus shanty texts are far more fluid than published versions would indicate. The function of such songs may be twofold: to synchronize the group's muscular effort, and to afford diversion from the wearisome nature of the task. The practice is ancient and widespread, being found in nearly all parts of the world, except where mechanical hoists, motor-driven winches, and such have made it superfluous. The Far East and Bantu Africa are notably rich in this kind of song.

In Britain and North America the term "shanty" is applied particularly to the songs used to accompany hauling, pumping, and capstan work aboard sailing ships. In English vessels, shanty singing rather fell into abeyance during the 17th century when merchant ships came, more or less, under naval discipline, but the practice revived vigorously in the 19th century when the newly formed shipping lines, each anxious to complete voyages more rapidly than its rivals, found that "a good shantyman was worth four extra hands on the rope." Thus, despite their primitive-seeming cast of melody and poetry, most of the well-known English-language shanties were evolved between 1825 and 1875, by

which time sail was giving way to steam and group work aboard ship was diminishing. (A. L. Ll.)

SHAPING MACHINE: *see* Machine Tools; Lathe; Woodworking Machinery.

SHAPLEY, HARLOW (1885–), U.S. astronomer, pioneer in studies of the structure of the Milky Way and of the universe beyond it, was born in Nashville, Mo., on Nov. 2, 1885. After studying at the University of Missouri and at Princeton, he joined the staff of the Mount Wilson Observatory in 1914, and later became professor of astronomy at Harvard University. From 1921–52 he was director of the Harvard College Observatory.

Shapley's most important early work concerned eclipsing binary stars. With H. N. Russell, in 1913, he devised practical methods for deducing the dimensions of the component stars of these systems from measurement of the light variation during eclipse. These methods, in essentials, remained the standard procedure for more than 30 years. Shapley showed that Cepheid variables cannot be eclipsing binaries, and was the first to advocate the theoretically important view that they are pulsating stars.

He studied the colours and magnitudes of stars in clusters, especially of those in the globular clusters, and was a pioneer in the use of variable stars (Cepheids and RR Lyrae stars) as distance indicators. He made the bold hypothesis, then revolutionary but later well established, that the globular clusters form a fairly symmetrical swarm about the centre of the Milky Way and that our sun must therefore be located in the outer parts of the Milky Way system, some tens of thousands of light years from the centre.

With the aid of large numbers of photographs of the sky, made both at Harvard and at the Harvard southern station in South Africa, Shapley studied the structure of the Milky Way and of nearby galaxies, especially the Magellanic Clouds, and the distribution of galaxies in space. He was one of the first to demonstrate that galaxies tend to occur in clusters and that the Milky Way is a member of a local cluster.

Shapley's work, characterized by bold imagination and drive, was mainly of the nature of first surveys. As he himself pointed out in the late 1950s, much further detailed investigation was required.

Shapley's works included *A Source Book in Astronomy*, with H. E. Howarth (1929), *Star Clusters* (1930), *Flights from Chaos* (1930), *Galaxies* (1943), *Inner Metagalaxy* (1957), *Of Stars and Men . . .* (1958). He edited *Climatic Change* (1954); *A Treasury of Science*, 3rd rev. ed., with S. Rapport and H. Wright (1954). He also wrote many technical papers, especially in the *Astrophysical Journal* and in the *Proceedings of the National Academy of Sciences*. (R. O. R.)

SHAPUR (Pahlavi Shahpuhr, "son of the king"; Greek Sapores; commonly Sapor), the name of three Sasanian kings of Persia.

Shapur I (according to T. Nöldeke, reigned A.D. 241–272; to W. B. Henning, 239–270, and to S. H. Taqizadeh, 241–273), son of Ardashir I and second in line of the Sasanian kings. The Persian legend that makes him the son of an Arsacid princess is not historical. Ardashir, toward the end of his reign, had renewed the wars against Rome inherited from the Arsacids. On his death Shapur continued the war, conquering Nisibis (Nusaybin) and Carrhae (Harran) and advancing deep into Syria. Defeated at Resaena in 243, he was yet able to conclude an advantageous peace in 244 because of the murder of the emperor Gordian III. In 256 he took advantage of the internal chaos within the Roman Empire to renew his attacks. Invading Syria, Asia Minor, and Armenia, he sacked Antioch but was repulsed by the emperor Valerian. However, in 260 Shapur not only defeated Valerian at Edessa but captured him and kept him a prisoner for the rest of his life. The capture of Valerian is a favourite subject of Sasanian rock carvings. In attacking the eastern Roman provinces, Shapur does not appear to have aimed at a permanent occupation. He merely carried off enormous booty both in treasure and men. The captives from Antioch were set to work to build the city of Gunde-Shapur (called in an inscription *Vahy-Andiok-Shapuhr*, "better than Antioch [has] Shapur [built]"), later to become famous as a centre of learning. Using the same captives, who excelled the Persians in technical skill, he built the dam at Shushtar known to this day as the Band-i-Qaisar, "the dam of Caesar."

Shapur was no longer content to describe himself as "king of kings of Persia" as his father had done: he styled himself "king of kings of Persia and Aniran (Aneran)," that is to say, of non-Persian territories as well. Possibly in connection with these secular imperialist ambitions Shapur appears to have tried to find a religion that would be suitable to all his subjects, whether of Persian stock or not. He showed marked favour to Mani, the founder of Manichaeism (*q.v.*), and at least one of his brothers adopted the Manichaean faith. He himself does not seem to have taken this final step, for the inscriptions show that he founded Zoroastrian fire temples both on his own behalf and on behalf of his wife and sons. He sought, however, to broaden the basis of the newly revived Zoroastrian religion by the addition of material derived from both Greek and Indian sources; there is evidence that he favoured the heretical "Zurvanite" wing of Zoroastrianism which derived both Ahura Mazda and Ahriman, God and the devil, from the principle of Infinite Time.

If the credit of the founding of the Sasanian empire belongs to Ardashir I, it was nevertheless Shapur who consolidated and expanded it. He thought of the new empire as a multinational state in which Manichaeism, drawing on Christian and Buddhist as well as on Zoroastrian sources, might serve as a unifying factor.

Shapur II (310–379), usually called "the Great," ninth of the Sasanian kings. At the death of Ormizd II, the Persian nobles killed his eldest son, blinded the second, and imprisoned the third. The throne was reserved for the unborn child of one of the wives of Ormizd. This was Shapur, who was thus born king.

With the adoption of Christianity by Constantine the Great and the subsequent christianization of the Roman Empire, Persia found itself saddled with what it considered to be a powerful Christian "fifth column." Thus Shapur resumed the policy of fierce intolerance toward non-Zoroastrians which had been initiated by the high priest Kartir in the reign of Bahram I, and singled out the Christians for persecution. He summoned a conference of all creeds, and decided in favour of one Adhurbadh, son of Mahraspand, a dualist Zoroastrian of strictly orthodox views. Thus Shapur II sought to unite his empire by enforcing Zoroastrian orthodoxy on frequently unwilling subjects.

His external policy was one of war and expansion; during his reign the insane and semipermanent struggle between the rival empires of Rome and Persia swayed in favour of the latter. In 337 Shapur broke the peace which had been concluded 40 years before between Narses and Diocletian and embarked on a 26-year war. Shapur attempted with varying success to reduce the great Mesopotamian fortresses of Singara, Nisibis, and Amida (Diyarbakir). Though the Roman emperor Constantius II was invariably defeated on the field, Shapur made little real progress. He was not strong enough to occupy permanently the conquered provinces because his eastern frontier was continually raided by central Asian tribes, prominent among which were the Chionites (*see* Hephthalites). After a prolonged struggle Shapur finally forced their king Grumbates to conclude a peace, whereupon the latter allied himself to Shapur in a renewed onslaught on the Roman power. With Grumbates' aid Shapur at last reduced both Amida and Singara (359–360). In 363 the emperor Julian advanced against him in force but was killed in battle. His successor, Jovian, was defeated and made to sign an ignominious peace by which he ceded the frontier marches on the Tigris and Nisibis and gave the Persians a free hand in Armenia. This victory is celebrated in the rock carvings near Shapur, not far from the modern Shiraz.

Shapur then turned his attention to the subjugation of Armenia. He captured the pro-Roman Arsaces III and imprisoned him in Susiana (Elam), where he committed suicide. His attempt to force Zoroastrianism on an Armenia which had only just accepted the Christian faith met with fierce and successful resistance. Arsaces' son Pap was smuggled out into Pontus and the Armenian resistance remained unbroken. The emperor Valens succeeded in restoring Pap in violation of the treaty concluded between Jovian

and Shapur, but Pap repaid him by poisoning the patriarch, Nerses, the very symbol of national resistance, and executed Cylax and Artaban, the leaders of the anti-Persian party. In so doing he may have been trying to preserve a precarious balance between Persia and Rome in Armenia. Be this as it may, he was treacherously murdered by the Romans in or about 374.

For five years Armenia was progressively weakened by an internecine struggle among its nobles. Shapur's last act was to win over Armenia by a discreet distribution of gifts. The country's autonomy under Persian suzerainty was recognized and the Christian religion respected. Thus Shapur II left Persia with its territory considerably augmented: he had pacified the eastern frontier and gained suzerainty over Armenia. The Persian empire had never been stronger; but war with Rome became a natural state of affairs, and its continuance did more than anything to undermine the strength of the Sasanian empire.

SHAPUR III (383–388), son of Shapur II, was raised to the throne by the nobles against his uncle Ardashir II, and killed by them after a reign of five years. He concluded a treaty with Theodosius the Great. (R. C. Z.; X.)

SHARECROPPING, though it is usually thought of as a form of crop-share renting, is essentially a labour contract involving payment in kind. The landowner furnishes the land, sources of power (such as a mule), usually a house, and sometimes food, clothing, and medical expenses. The sharecropper furnishes his labour, usually working under the close supervision of the landowner, who retains the right of possession and control of the land and crops. In most jurisdictions, the sharecropper is legally a labourer with a statutory lien for his labour upon the property of his employer.

Ordinarily the crops, usually cotton and tobacco, are shared 50–50, but they may be divided in other proportions. The cropper's share of production costs and advances for living expenses are deducted from his share of the crop.

With the introduction of modern machinery and technology, sharecropping has declined in importance. The furnishing of living expenses has largely disappeared, as have quasi-peonage and other questionable practices.

See METAYAGE SYSTEM; FARM TENANCY; SOUTH, THE: *Sharecropping.* (M. D. H.)

SHARI (CHARI), the principal river feeding Lake Chad in north-central Africa. It flows through the Republic of Chad and the Central African Republic. It is formed by a series of smaller rivers: the Bamingui, considered as the true headstream of the Shari, but in the dry season carrying little water, drains the region of Dar Kouti; the Gribingui rises south of Fort-Crampel and is a river of considerable size when it joins the Bamingui at Irena; the Ouham, or Bahr Sara, a long river coming from the Yade massif which at times flows through a great marshy valley, and in places is interrupted by rapids, particularly upstream from Batangafo at its confluence with the Fafa. The Ouham brings the greatest volume of water to the Shari. Near Fort-Archambault the Shari is joined on its right bank by the Aouk, the Bahr Kéita, and the Bahr Salamat, the waters of whose parallel courses mingle in an immense floodplain. The Bahr Salamat is the longest; its upper branch, the Bahr Azoum, rises in the volcanic hills of Darfur. Other rivers from the slopes of Hadjer Telfân and Massif de Guéra also join the Salamat. In its middle course the waters of Lake Iro drain into it and the river divides into numerous branches which spread into a delta and end in the Shari. The Aouk, which forms the boundary between the republics of Chad and Central Africa, also rises in Darfur in the Sudan and drains sluggishly an immense marshy plain. In the dry season it is sometimes reduced to a succession of stagnant ponds; it empties its flood waters into the Shari in an extensive delta.

Downstream from Fort-Archambault the Shari crosses the Gay Rapids, at the high ground near Niellim. From there on it is a large slow-running river, 3 to 4 mi. wide, which may reach 6 mi. in time of flood, and its lower reaches divide into many channels. It pushes west across the level plain toward the Logone, which for many miles flows parallel to it; the two floodplains are linked by the Ba Illi. At Fort-Lamy, where the Shari is no longer tortuous and frequently overflows its crumbling banks, the two rivers unite and flow on into Lake Chad (*see* CHAD, LAKE) through several distributaries including the Serbewel, the largest, the Ebeji-Ngada, and the Taftaf. Total length of the Shari between Fort-Lamy and Fort-Archambault is 869 mi. (1,398 km.). The Shari basin covers 231,600 sq.mi. (600,000 sq.km.) and the river unites the drainage of the southern part of the Chad inland drainage basin.

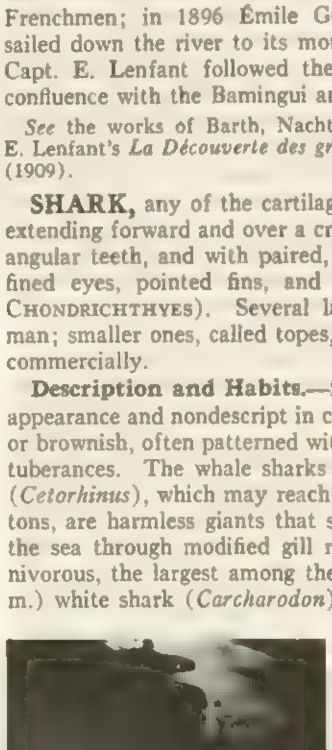
Steam navigation is possible for more than 680 mi. (1,100 km.) on the main rivers in the wet season, as far as Baïbokoum on the western Logone (Mbere), Goré on the eastern Logone (Pendé), Batangafo on the Ouham, and Irena on the Gribingui. The average annual rate of flow at Fort-Lamy is 1,230 cu.m. per sec., but it may exceed 4,500 cu.m. per sec. in time of flood.

The existence of the Shari was made known by Dixon Denham, Hugh Clapperton (*qq.v.*), and Walter Oudney, the first Europeans to reach Lake Chad (1823). In 1852 Heinrich Barth (*q.v.*) spent some time in the region of the lower Shari and Logone, and in 1872–73 Gustav Nachtigal (*q.v.*) studied the hydrographical system of these rivers and explored the Gribingui, which he called the Bahr el Ardhe. The most prominent explorers have been Frenchmen; in 1896 Émile Gentil reached the Bamingui and sailed down the river to its mouth; in 1904 an expedition under Capt. E. Lenfant followed the Ouham from its source to the confluence with the Bamingui and discovered the eastern Logone.

See the works of Barth, Nachtigal, and other travelers, especially E. Lenfant's *La Découverte des grandes sources du centre de l'Afrique* (1909). (J. D.)

SHARK, any of the cartilaginous fishes with a pointed snout extending forward and over a crescentic mouth set with sharp triangular teeth, and with paired, largely lateral, gill slits, well defined eyes, pointed fins, and a muscular, upturned tail (*see* CHONDRICHTHYES). Several larger kinds can be dangerous to man; smaller ones, called topes, hounds, and dogfishes, are fished commercially.

Description and Habits.—Shark species are often similar in appearance and nondescript in colour, varying from gray to bluish or brownish, often patterned with spots, bands, marblings, or protuberances. The whale sharks (*Rhincodon*) and basking sharks (*Cetorhinus*), which may reach 50 ft. (15 m.) and weigh several tons, are harmless giants that subsist on plankton strained from the sea through modified gill rakers. All other sharks are carnivorous, the largest among them being the voracious 40-ft. (12 m.) white shark (*Carcharodon*), which attacks seals, sea turtles, large fish, and, on more than one occasion, man (see *Hazards to Man*, below). The sluggish Greenland shark (*Somniosus*) of cold, deep waters has been known to feed on seals, reindeer, large fish, and whales. Normally sharks feed on fish, often attacking in schools; open-ocean species such as the mackerel, mako, and thresher sharks frequently feed near the surface, and are much sought after by rod and reel sportsmen as prime game fish. Beautifully streamlined and powerful swimmers, these open-ocean sharks are adept at feeding on fast tuna, marlin, etc. Bottom-feeding sharks are stout, blunt-headed forms, tending to flattened bodies with well developed spiracles and larger eyes; the shellfish eaters have coarse, pavementlike crushing teeth. By far the oddest looking sharks are the hammerheads (*Sphyrna*), whose heads resemble double-headed hammers



BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

SAND SHARK (CARCHARIAS TAURUS)

and have an eye on each stalk. So characteristic are shark teeth that it is possible to identify fossil and modern species from one or two teeth.

The origin of sharks is obscure, but their geological record goes back to pre-Devonian times (more than 320,000,000 years ago). Their present diversity of forms and numbers, estimated at some 300 species, equals their past abundance; many recently found species have long been known from the fossil record.

The living sharks (order Pleurotremi) fall into three suborders. The first is the Notidanoidea, a small group of primitive sharks distinguished by six or seven gill clefts and one dorsal fin; examples are the frilled (*Chlamydoselachus*) and six-gilled (*Hexanchus*) sharks. These are deepwater fishes; the former are eel-shaped and may reach over 6 ft. (2 m.); the latter attain a length of over 25 ft. (8 m.). The suborder Squaloidea is characterized by five, rarely six, gill clefts and two dorsal fins preceded by spines. This group includes the bullheaded, or horn, shark (*Heterodontus*); the spiny dogfish (*Squalus*), a small shark of temperate seas, which travels in schools and is a pest to commercial fisheries; the bramble shark (*Echinorhinus*), a bulky shark with spiny tubercles on the skin; and the Greenland shark, which grows to 20 ft. (6 m.). The specialized saw sharks (*Pristiophorus*) and the bottom-dwelling angel sharks (*Squatinidae*) with elongated bodies and muscular tails are also of this suborder. The third suborder, the Galeoidea, are typified by five gill clefts, two spineless dorsal and one anal fin. The bulk of the sharks, and many aggressive representatives of the requiem sharks (Carcharinidae), feared because of their attacks on man, are associated with the galeoids. This suborder also includes the families Odontaspidae (the sand and elfin sharks), Lamnidae (man-eater, porbeagle, basking, mackerel, and thresher sharks), Carchariidae (topes, hounds, blue, and hammerhead sharks), Scyliorhinidae (dogfishes), and Orectolobidae (carpet, tiger, nurse, and whale sharks).

Although chiefly marine, sharks often enter fresh water; requiem sharks of the genus *Carcharhinus* occur commonly in the Zambezi, Tigris, and Ganges as well as other rivers in subtropical and tropical areas. The Lake Nicaragua shark is a landlocked form found in Central American lakes. *Carcharhinus* species are small to medium sized, but are aggressive, persistent, and generally feared.

Hazards to Man.—In Australia, South Africa, and elsewhere along coasts exposed to the shark nuisance, public beaches are often provided with lookout towers, bells and sirens, or nets—proof of public concern toward the shark hazard. The most feared species is the great white shark, whose erratic presence in United States coastal waters has given rise to particularly distressing attacks in Buzzard's Bay, Mass., off the New Jersey shore and, with most frequency, along the California coast. Other sharks involved in attacks on humans are the tiger (*Galeocerdo*), blue (*Prionace*), gray nurse (*Carcharias*), and hammerhead.

Of course, the larger the shark the more formidable the attack, but several small specimens can be equally hazardous, a fact well attested to by wartime sea survivors. The zone of greatest hazard lies approximately between latitudes 40° N and 40° S and coincides with the warmer months, when average surface sea temperatures vary between 60° and 70° F (16° and 21° C). Fatalities are greatest in late afternoon; men have been attacked more frequently than women. The majority of attacks are on bathers in shallow water (between 2 and 3 ft. [0.6 to 1 m.]); however, participants in underwater activities also risk injury from sharks in warm seas. (The above information, however, may reflect the habits of bathers as well as the habits of sharks; bathers are most numerous under the conditions listed.) Injury is greatest on the lower limbs and buttocks and, secondarily, on the forearms and hands. Mortality is as high as 70%; this is largely due to hemorrhage and shock, controllable through first-aid measures. Increasing public interest in seashores for recreation and sport emphasizes the need for uniform safety measures to prevent loss of life. The incidence of attack by sharks is no greater than that for land carnivores, but the probability of a rise in shark attacks is greater since increasingly greater numbers of people, with little realization of marine hazards, are entering the sea during the season when sharks are closest to the shore. Shark repellents are constantly being sought; several, like "Shark Chaser," consisting of copper acetate and a black marker dye, nigrosine, in a water-soluble wax, appear to be some help in repelling some species.

Economic Importance.—Shark fishing is a relatively minor industry of local importance in a few regions. Shark-liver oil, high in vitamin A, has been used for pharmaceutical and proprietary medicines when supplies of cod-liver oil, formerly a chief source of the vitamin, have been reduced. Lower-grade shark oils have industrial application in tanning and other industries. Shark skin is the source of shagreen, a very durable leather for which there is only a very limited demand. Spiny (*Squalus*) and smooth (*Mustelus*) dogfishes serve as objects of anatomical dissection in many school laboratories of zoology. Past attempts in the United States to popularize spiny dogfish (*Squalus acanthias*) flesh as edible "gray fish" proved unsuccessful. However, the use of shark flesh elsewhere is more widespread; large quantities are sold in Europe, South America, and South Africa. In Latin-American countries sun-dried or salted shark flesh is shipped inland.

The school shark (*Galeorhinus australia*), originally fished for vitamin A in Australia, is now processed into fresh shark fillets. Several million pounds annually are sold as "flake," the principal source of fish in "fish and chips"; the Australian government has been concerned with the dwindling number of this commercially valuable species in its territorial waters. (Strangely enough, regardless of where shark flesh is sold, it rarely is described as a shark product.) Sharks are also used as bait for lobsters and crabs, and considerable amounts of shark meat are processed for fertilizer and for livestock feed.

SHARP, CECIL JAMES (1859–1924), English musician whose work as a collector of English folk song and dance had an important influence on 20th-century British music, especially on Gustav Holst and Ralph Vaughan Williams, was born in London on Nov. 22, 1859. Educated at Uppingham and Cambridge University, he was self-taught as a musician. In 1882 he emigrated to Australia, where, after some false starts, he became assistant organist of Adelaide Cathedral and co-director of the Adelaide College of Music. In 1892 he returned to England and obtained posts as music master at Ludgrove School (1893–1910) and principal of the Hampstead Conservatoire (1896–1905).

In 1903 Sharp discovered that an unsuspected wealth of native folk song survived in England. Although work in this field had already been begun, the publication of Sharp's collection *Folk Songs from Somerset* (1904–09) and of his study *English Folk Song: Some Conclusions* (1907; 3rd ed. rev. by M. Karpeles, 1954) led to a new and widespread interest in English folk music. He was invited to lecture and to teach the songs, and later the dances, which he had begun to collect in 1905; and his life's purpose became the collection and performance of folk music. In 1911 he founded the English Folk Dance Society (later to be amalgamated with the Folk Song Society); he demonstrated and taught annually at the Vacation School of Folk Song and Dance at Stratford-upon-Avon; and he initiated the teaching of folk song and dance in English schools.

Between 1916 and 1918 Sharp three times visited the United States to teach and to collect songs of English origin. His reputation in the U.S. was established by the publication, with Olive Dame Campbell, of *English Folk Songs from the Southern Appalachians* (1917; enlarged and edited by M. Karpeles, 1932; rev. ed., 1960). In 1923 he received the honorary degree of Mus.M. at Cambridge. He died in London on June 23, 1924.

Sharp's other published works include *English Folk Songs* (1921; reprinted 1959) and teaching handbooks of morris, sword, and country dances.

See A. H. Fox-Strangways and M. Karpeles, *Cecil Sharp* (1933; rev. ed., 1955). (M. J. D.-S.)

SHARP, JAMES (1618–1679), archbishop of St. Andrews from 1661, who was largely responsible for the reintroduction of

episcopacy in Scotland after the restoration of Charles II, was born on May 4, 1618. A native of Banffshire, he grew up in the episcopalian and royalist tradition, and after the presbyterian triumph and the abolition of episcopacy in Scotland in 1638, went to England. Returning in 1643, he taught at St. Andrews University, later becoming minister of Crail, in Fife (1649). The presbyterians were divided into two factions, and Sharp sided with the more moderate and royalist "Resolutioners" against the extreme "Protestors." In 1657, as the spokesman of the Resolutioners before Oliver Cromwell in London, he showed ability that won him much esteem.

Sharp took part in the negotiations leading to the restoration of Charles II, and in 1660 again represented his party in London. He soon saw that the drift in England toward the restoration of episcopacy would affect Scotland. Being leader of the moderate party, he was consecrated archbishop of St. Andrews on Dec. 15, 1661. Most of the Resolutioners acquiesced in episcopacy, but to the Protestors and all who adhered to presbyterianism Sharp was a scheming traitor. He therefore bore the odium for many unpopular government measures (*see* SCOTLAND: *History*), but the truth is that his determination to retain his position made him merely compliant with the Privy Council, whatever its policy. Thus, although Sharp disapproved of the Act of Supremacy of 1669, giving the crown supreme power in all church affairs in Scotland, he did not imitate Archbishop Alexander Burnet of Glasgow, who was deprived because of his opposition.

An attempt was made to assassinate Sharp in Edinburgh on July 11, 1668. A presbyterian, James Mitchell, arrested in 1674, confessed to the crime on a promise of his life, but was nevertheless executed in 1678. This affair intensified antipathy to the archbishop. On May 3, 1679, while driving to St. Andrews with his daughter, he was murdered on Magus Muir, 3 mi. W of St. Andrews, by a band of fanatical presbyterians. (GN. D.)

SHARP (IN MUSIC): *see* ACCIDENTALS.

SHARPEY-SCHÄFER, SIR EDWARD ALBERT (1850–1935), British physiologist and inventor of the prone-pressure method of artificial respiration (*q.v.*), was born at Hornsey, Middlesex, on June 2, 1850. He was educated at University College, London, where he met William Sharpey, the professor of general anatomy and physiology, and in 1918 he prefixed Sharpey's name to his own in order to perpetuate the name of his teacher. He became Jodrell professor at University College (1883), Fullerian professor at the Royal Institution (1878–81), and professor of physiology at Edinburgh University (1899–1933). Sharpey-Schäfer made important contributions to the knowledge of cerebral localization, of the heart sounds, and of muscular contraction. In 1894 (with George Oliver) he demonstrated the existence in the adrenal glands of a substance (adrenaline) which raised the blood pressure, and this stimulated research on the internal secretions (hormones) of the ductless glands. Sharpey-Schäfer's method of artificial respiration was adopted by the Royal Life Saving Society, and he received many honours, including the presidency of the British Association (1912) and a knighthood (1913). He died at North Berwick, East Lothian, on March 29, 1935.

(W. J. BP.)

SHARQIYAH, ASH, a *muhafaza* (governorate) of Lower Egypt (United Arab Republic) in the east of the Nile Delta, reaches the Mediterranean Sea in the northeast and is bounded by the Suez Canal Zone in the east, by the Eastern Desert (As Sahra' ash Sharqiyah) in the south, and by the *muhafazat* of Al Qalyubiyah in the southwest, and Ad Daqahliyah in the west. Area 1,815 sq.mi. (4,700 sq.km.); pop. (1960) 1,819,798, giving a density of 1,003 persons per square mile. The capital and only large town is Az Zaqaziq (Zagazig).

Much of the area's development dates from the mid-19th century with the spread of cotton growing in the Nile Delta. New canals, especially the Ismailia or Sweet Water Canal (1863), carrying fresh water from the Nile to the Suez Canal Zone, converted the eastern part of the territory from desert into fertile farmland. However, to the northeast contiguous with Lake Manzilah there lies a large area of saline marsh. Reclamation of this marsh and the lake area proceeded slowly in the 1960s, with rice as the main crop of the reclaimed farmland. The principal crops are maize (corn), barley, cotton, wheat, and rice. Peanuts and sesame are important in the sandy soils to the east. About 65% of the occupied population is engaged in agriculture. The principal water for irrigation is obtained from the Ismailia and Muways canals. Fisheries are important in Lake Manzilah. The principal industries are related to the agricultural resources. There are no mineral resources. (A. B. M.)

SHASI (SHA-SHIH), a commercial city and water transportation centre on the Yangtze in central Hupeh Province, China. Pop. (1953) 85,800. Called "Little Hankow" after the most important commercial port of central China about 120 mi. (190 km.) eastward, Shasi is the centre for numerous canal connections, one of which shortens to a third the circuitous Yangtze River distance to the Wu-han metropolitan area. Across the Yangtze and southward, the T'ai-p'ing and Ou-ch'ih canals lead to Tung-t'ing Lake in Hunan. Between these two canals a flood-detention basin covering 350 sq.mi. (900 sq.km.) was constructed in 1952–53. Because of its situation in the cotton-growing region of Hupeh, cotton and cotton seed, as well as other produce such as rape seed, are exported through Shasi. The city also is a distribution point for upriver Szechwan salt. Cotton textile and flour mills west of the city form two of its most important industries. Shasi has no rail connections but a motor highway runs south from across the Yangtze around Tung-t'ing Lake to Ch'ang-sha, and another highway runs north to Hsiang-yang on the Han River.

Shasi was flourishing as early as the T'ang dynasty, and superseded in the 1870s contiguous Chiang-ling (formerly Ching-chou, which dates far earlier) as the local commercial centre. Shasi was one of the treaty ports opened in 1896. (H. J. WS.)

SHASTA, a Hokan-speaking group of North American Indians, lived on and south of the Klamath River in California, east of Mt. Shasta. Culturally they stood intermediate between the northwestern tribes, such as the Yurok and Hupa (*qq.v.*), and the Maidu (*q.v.*) and other central Californians. When first encountered by whites (early 19th century) the Shasta were sedentary villagers who collected roots and seeds, relying largely on salmon for animal food. Houses were of wooden planking and built about half below ground level. They used dugout canoes, spears, bow and arrow, weirs, and nets. Numbering an estimated 2,000 in 1770, they dwindled to a few dozen scattered households in the second half of the 20th century; two Shasta communities with a combined population of 130 were reported from northern California in the 1960s. *See* also HOKAN.

See J. R. Swanton, *The Indian Tribes of North America* (1953); F. W. Hodge (ed.), *Handbook of American Indians North of Mexico* (1959).

SHASTRI, LAL BAHADUR (1904–1966), Indian leader, prime minister of India in succession to Jawaharlal Nehru, was born on Oct. 2, 1904, at Mughalsarai in the United Provinces (later Uttar Pradesh). He went to school in Benares (Varanasi) until the age of 17, when he joined the noncooperation movement and was imprisoned for a short time. On his release he studied in the Kashi Vidyapith, a school specializing in religious and nationalist instruction, where he was awarded the title of "Shastri" (learned in the scriptures). He then returned to politics, was imprisoned several times, and attained influential positions in the local Congress Party hierarchy. He was elected to the United Provinces legislature in 1937 and again in 1946. After Indian independence Shastri gained experience as minister for home and transport in Uttar Pradesh. He was elected to the central Indian legislature in 1952 and became union minister for railways and transport. He resigned in 1956 because he felt that he was constitutionally responsible for a serious railway accident, but returned to office in 1957. He gained a reputation as a skilful mediator after his appointment to the influential post of minister for home affairs in 1961, but he resigned in 1963 under a plan whereby ministers should voluntarily leave office to devote themselves to the reform of the Congress Party. In January 1964, on Jawaharlal Nehru's illness, he was recalled to the cabinet as minister without portfolio, and after Nehru's death he became prime minister (June 9, 1964). Before the end of that month, he suf-

fered a heart attack. He was of slight, almost frail, physique, and there were fears that he might not be able to stand the strain of his office. He was criticized for failing to deal effectively with economic problems but won great popularity for his firmness on the outbreak of hostilities with Pakistan (1965). He died of a heart attack at Tashkent, in Soviet Central Asia, on Jan. 11, 1966, after signing a "no-war" agreement with Pres. Ayub Khan of Pakistan.

Shastri was unassuming and unpretentious in manner, and devoid of doctrinaire views. His strength lay in the general recognition of his administrative competence and in the respect for his upright character. *See* also INDIA: *History*.

SHAVUOTH (SHABUOTH): *see* JEWISH HOLIDAYS.

SHAW, GEORGE BERNARD (1856–1950), the most important British comic dramatist since Congreve, was born in Dublin on July 26, 1856. His ancestry lay among the Protestant landed gentry, but his father was first a minor civil servant and later an unsuccessful wholesale merchant, so that he grew up in an atmosphere of polite urban indigence. He largely rejected the indifferent education offered by the schools he attended (beginning in 1867 with the Wesleyan Connexional School—later Wesley College), but developed a wide knowledge of music, art, and literature, as a result of home influence and visits to the National Gallery of Ireland. By the time he was 16, he was working as a land agent's clerk. In 1872 his mother virtually abandoned her husband, and took her two daughters to London, following George Vandaleur Lee, her singing teacher (with whom the Shaws had shared a house in Dublin and a cottage at Dalkey since *c.* 1866), upon whom her hopes of a musical career depended.

Early Years in London.—In 1876 Shaw resolved to become a writer, and joined her and his elder sister (the younger having died). He thus left Ireland for 29 years, returning then only for a visit. The emotional temperature of the family seems to have been low, and Shaw and his mother took little interest in each other. But they lived together until he married in 1898, the household making do on her earnings as a music teacher, and on £1 a week from her husband in Dublin, augmented, after 1877, by Shaw's share of a family bequest.

Shaw wrote five novels in steady succession: *Immaturity* (written 1879, publ. 1930); *The Irrational Knot* (serialized 1885–87; as a book, 1905); *Love Among the Artists* (1887–88; as a book, Chicago, 1900); *Cashel Byron's Profession* (1886, several times revised; a dramatic version, *The Admirable Bashville*, being appended to the 1901 edition); and *An Unsocial Socialist*, the last novel completed, and the first to be printed (serially, 1884; as a book, 1887). A fragment of a sixth novel, begun in 1887, was published in 1958. It is now possible to find much that is agreeably "Shavian" in these works. But they had little success, and for a decade Shaw's industry earned him less than 10*s.* a year. He read in the British Museum, became a vegetarian, joined the recently founded Fabian Society (*q.v.*) in 1884, and began his long career as a public speaker.

THE GRANGER COLLECTION

GEORGE BERNARD SHAW, PHOTOGRAPHED IN HIS GARDEN AT AYOT ST. LAWRENCE, ENGLAND

Eventually, in 1885, William Archer (*q.v.*), whom he had met in the British Museum reading room, found him employment as a book reviewer on the *Pall Mall Gazette* and art critic on the *World* (1886–89); and then as a writer on music in the *Star* (1888–90) and the *World* (1890–94). He had a good acquaintance with music, particularly opera, and eked out his knowledge with a brilliance of digression that makes many of his notices permanently delightful. His first real mark, however, was made as drama critic on the *Saturday Review*, to which he was recruited in 1895 under the editorship of Frank Harris.

Marriage and Success.—By this time Shaw was a playwright, and his energies began to concentrate themselves on drama. In 1898, after an illness caused by overwork, he married Charlotte Payne-Townshend (d. 1943), an Irishwoman of good family who combined progressive political views with considerable fortune. He had met her when staying with his friends Sidney and Beatrice Webb, and she had nursed him during his illness. Shaw was not in the common sense a passionate man, and what may be called the two love affairs of his life, with Ellen Terry and Mrs. Patrick Campbell (*qq.v.*), seem to have been mainly conducted by letter.

His marriage established him in a settled mode of living. Although he remained an active Socialist, he was henceforward essentially a dramatist. He was fond of declaring that he was "a social reformer and doctrinaire first, last, and all the time." But it was the theatre that he loved, although he insisted on surrounding his work with manifestos, and on importing into it a strong polemical tone. He was in every sense a showman, and kept himself in the public eye by a sort of intellectual clowning. When he died at 94 (at Ayot St. Lawrence, Hertfordshire, on Nov. 2, 1950), he had long been the greatest living man of letters in the English-speaking world.

In 1925 he had been awarded the Nobel Prize for literature (using the money to establish the Anglo-Swedish Literary Foundation for translation of Swedish literature into English); his plays, often popular in the United States before they were appreciated in England, were performed in most European countries; his political writings—notably in *Fabian Essays in Socialism*, which he edited for the Fabian Society (1889); *The Common Sense of Municipal Trading* (1904; new ed. 1908), a result of his experience as vestryman and borough councilor of St. Pancras, London (1897–1903); *Common Sense About the War*, published (November 1914) as a supplement to the *New Statesman*, which he had helped to found in 1913; works on Irish nationalism (1917 and 1920), on the League of Nations (1929), and *What I Really Wrote About the War* (1931)—were widely read and influential; and his personality had made an unusually wide impact. He conducted a large correspondence—often on postcards—and, although burdened by a marked constitutional shyness, made many friendships with notable contemporaries (*e.g.*, T. E. Lawrence). His will revealed the breadth of his interests. What remained of his fortune of more than £300,000 after death duties were paid was left in trust for research on a "Proposed British Alphabet" of at least 40 letters; the residue to be divided between the National Gallery of Ireland, the British Museum, and the Royal Academy of Dramatic Art. Shaw's Corner, at Ayot St. Lawrence, his home since 1906, was left to the National Trust.

The Plays.—*"Unpleasant and Pleasant."*—When Shaw began writing for the English stage its most prominent dramatists were Sir A. W. Pinero and H. A. Jones (*qq.v.*). Both were concerned to develop a modern realistic drama; neither had the power to break away from the type of threadbare artificial plot expected by theatregoers. (*See* also DRAMA: *Modern Drama.*) The poverty of this sort of drama had become apparent in 1889, when Ibsen's *A Doll's House* was played in London; his *Ghosts* followed in 1891, and the possibility of a new freedom and seriousness on the English stage was introduced. Shaw, about to publish *The Quintessence of Ibsenism* (1891; completed, 1913, to Ibsen's death), rapidly refurbished an abortive comedy, *Widowers' Houses*, as a play recognizably "Ibsenite" in tone, making it turn on the notorious scandal of slum landlordism in London. The result (performed 1892), in both its strength and its limitations, is characteristic of much that was to follow. A well-intentioned young Englishman falls in love, and then discovers that his prospective father-in-law's fortune and his own private income derive from exploitation of the poor. Potentially this is a tragic situation, but Shaw seems

to have been always determined to avoid tragedy. The unamiable lovers do not attract sympathy; it is a social evil and not a romantic predicament on which attention is concentrated; and the action is kept well within the key of ironic comedy. The same dramatic predispositions control *Mrs. Warren's Profession,* written in 1893 but not performed until 1902, as the lord chamberlain refused it a licence. Its subject is organized prostitution, and its action turns on the discovery by a well-educated young woman that her mother has graduated through the "profession" to become part-proprietor of brothels throughout Europe. Again, the economic determinants of the situation are emphasized, and, although there is real horror for Vivie Warren in what is revealed to her, she is endowed with a certain hardness and coldness which ensure that her private dilemma shall not engage us at the expense of the public issues involved. The play is, within limits, a drama of ideas; the vehicle by which these are presented is essentially one of high comedy; here is something at once horrible and steadily entertaining.

Shaw called these plays "unpleasant," because "their dramatic power is used to force the spectator to face unpleasant facts"; he followed them with four "pleasant" ones. Both groups were revised and published in *Plays Pleasant and Unpleasant* (1898). The first of the second group, *Arms and the Man* (1894), has a Balkan setting and makes lighthearted, though sometimes mordant, fun of romantic falsifications of both love and warfare. The second, *Candida* (performed 1895), has more substance, and was important for English theatrical history, for its successful production at the Royal Court Theatre in 1904 encouraged Harley Granville-Barker (*q.v.*) and J. E. Vedrenne to form a partnership which resulted in a series of brilliant productions there. The play represents its heroine as forced to choose between her clerical husband —a worthy but obtuse Christian Socialist—and a young poet who has fallen wildly in love with her. She chooses her confident-seeming husband because she discerns that he is actually the weaker. The poet is immature and hysterical, but, as an artist, has a capacity to renounce personal happiness in the interest of some large creative purpose. This is a significant theme for Shaw; it leads on to that of the conflict between man as spiritual creator and woman as guardian of the biological continuity of the race which is basic to *Man and Superman.* In *Candida* such speculative issues are only lightly touched on, and this is true also of *You Never Can Tell* (performed 1899), which ends in a romp and is often farcical in tone. But when the hero and heroine, who believe themselves to be respectively an accomplished amorist and an impregnably rational New Woman, find themselves in the grip of a vital force which takes little account of these notions, we are again brought directly into contact with Shaw's emerging philosophy. This play is a light Gilbertian comedy given a novel twist.

"The Devil's Disciple."—The Devil's Disciple (performed New York, 1897; publ., in *Three Plays for Puritans,* with *Caesar and Cleopatra* and *Captain Brassbound's Conversion,* 1901) is melodrama similarly refreshed. It is set in New Hampshire during the American Revolution, and its hero, Dick Dudgeon, the black sheep of his family, is represented as heroically taking the place of a minister whom the English propose to hang. His motive is not (as the minister's wife supposes) romantic, but public and impersonal. Moreover, he acts spontaneously and at the command of some unquestioned imperative, so that his virtue is seen less as an achievement than as a profession: he is thus, surprisingly, distantly related to the characters in Corneille's dramas. Despite its serious implications, the play abounds in wit. The English General Burgoyne murmurs as the time of execution approaches: "We must not detain Mr. Dudgeon." And when the minister rushes in at the first stroke of 12, thanking God that he is in time, Burgoyne glances at his watch and says he would never dream of hanging any gentleman by an American clock.

"Caesar and Cleopatra," "Captain Brassbound," "Man and Superman."—Caesar and Cleopatra (performed 1906), Shaw's first great play, is a study in magnanimity, and outstandingly successful because the eminence upon which Caesar is set is never allowed to become a pedestal. When the great library of Alexandria goes up in flames and an agonized scholar cries out: "What is burning there is the memory of mankind," this lonely and austere man replies: "A shameful memory. Let it burn." But he does his best to educate Cleopatra, a spoiled and vicious child—and, moreover, he moves easily (and here consummate dramatic tact is at work) amid a crowd of minor characters who are simply and triumphantly amusing. In *Captain Brassbound's Conversion* (1900), by an extension of this technique, the voice of reason and good sense is set in the mouth of an aristocratic Englishwoman who is nevertheless a delightful figure of fun. The play is a sermon against various sorts of folly masquerading as duty and justice, but there is scarcely a speech that does not exhibit character or motive in an entertaining light. And this is true—except for a long and excrescent third act—of *Man and Superman* (publ. 1903, performed 1905). In outline it is merely the story of a ruthless and resourceful girl "out to get her man," but this is made the medium of sustained and scintillating debate upon the relationship of the sexes as it might variously appear in the light of sundry persuasions—moral and scientific, traditional and experimental—actually at play in the speculative climate of the early 20th century. Its hero, Jack Tanner, is the most intellectually resilient of Shaw's characters. At the same time—and particularly in the discursive third act—we may feel that he is being employed to explore the operatic rather than the intellectual boundaries of drama. Shaw himself declared, indeed, that opera had taught him to shape his plays into recitatives, ensemble finales, and the like, so as "to display the technical accomplishments of the executants." Behind *Man and Superman* there is still a Shaw belonging to the world of Karl Marx and Henry George, Sidney Webb and H. G. Wells, who believes that the human lot is to be ameliorated, and, indeed, the destiny of the human race to be determined, by purposeful activity at the level of enlightened legislation. But already there are doubts. The inverted "marriage by capture" with which the piece ends, when Ann claims Jack Tanner, scarcely suggests that controlled scientific mating is just round the corner. And further thought on the nature of evolution was to lead Shaw to very different conclusions.

"John Bull's Other Island" and "Major Barbara."—John Bull's Other Island (1904; publ., with *Major Barbara* and *How He Lied to Her Husband,* 1907) was intended for the Dublin Abbey Theatre, and its main aim was to exhibit to an Irish audience a comic Englishman as absurd as the many comic Irishmen on the London stage. Its background in Anglo-Irish relations has necessarily proved ephemeral, and, although it is often wildly amusing, it is not well-constructed. It has, however, a point of growth in the minor character of Father Keegan, in the portrayal of whom Shaw's interest in the religious consciousness emerges strongly. This is developed in the far richer *Major Barbara* (1905). Here the heroine, who has joined the Salvation Army, finds that her father, an armaments manufacturer, holds tenets which are in a way themselves religious. Barbara ranks next to Joan of Arc among Shaw's women, and some scenes are more moving than any that Shaw had hitherto allowed himself to write. On analysis the play may lack intellectual coherence, but it gains in dramatic vitality from the freshness of the doubts that lie behind it.

"The Doctor's Dilemma" to "Pygmalion."—Shaw now entered on a period of somewhat relaxed achievement. *The Doctor's Dilemma* (1906, publ., with *Getting Married* and *The Shewing-up of Blanco Posnet,* 1911) is a successful light satire on the medical profession, knit to a less convincing representation, in the consumptive painter, Dubedat, of the strengths and frailties of the artistic temperament. Shaw, himself a great creative artist, is seldom at his best in depicting artists. *The Shewing-up of Blanco Posnet* (1909) is a one-act play on a theme similar to that of *The Devil's Disciple. Getting Married* (1908) and *Misalliance* (1910, publ., with *Fanny's First Play* and *The Dark Lady of the Sonnets,* 1914) are dramatized debates on marriage and on parents and children, respectively. *Fanny's First Play* (1911) and *Overruled* (1912) are light exercises on familiar Shavian themes, rapidly run up upon tenuous artificial situations uncommon in Shaw. *Androcles and the Lion* (1913; publ., with *Overruled* and *Pygmalion,* 1916) returns, uncertainly, to exploration of religious sentiment by way of a group of early Christians condemned to the

arena. It is slight and in some danger of appearing frivolous. *Pygmalion* (1913) is another matter. This story of a flower girl trained by a phonetician to pass as a lady, although a most effective satire upon the English class system, is less a play of ideas than is any other of Shaw's major plays. Its richer human content has made it a favourite with a wide public, and it has achieved success in both film and musical versions. It is a masterpiece of comedy. The scene in which Eliza Doolittle appears in society when she has acquired a correct accent but no notion of polite conversation is one of the funniest in English drama.

"Heartbreak House" and "Back to Methuselah."—Heartbreak House occupies a special place in Shaw's work. Begun in 1913, published in 1919 (with minor pieces), and produced in New York in 1920, it ends with casualties and destruction caused by an air raid, but there is no other sign that the action takes place in wartime. Superficially it owes much to Chekhov, its theme being the boredom and frustration of a cultivated and sophisticated upper-middle-class social group conscious of lacking a system of beliefs and a function. The play seems to be the product of a more sombre vision than is readily reconcilable with its familiar comic machinery. The central character, Captain Shotover, is old and mad; and, although he tries to recall the heroine from a cynical despair induced by disillusioned love, his own sense of the plight of the modern world is expressed in his having turned his skill as an inventor to projects of universal annihilation. The play symbolizes the human race brought to an impasse by its subjection to modern scientific determinism.

This leads on naturally to *Back to Methuselah* (publ. 1921; performed in New York, 1922; rev. ed. with postscript "After Twenty-Five Years," 1945), five linked plays in which Shaw expounds his conception of Creative Evolution. "You imagine what you desire; you will what you imagine; and at last you create what you will" (the Serpent to Eve, Act I). The superman is no longer thought of as attainable through eugenic breeding. He will come—and come with a leap—only as the product of profound travail at the unconscious roots of Life itself. And in A.D. 2170 "the thing happens." Two characters whom we have met in the 1920s and judged undistinguished prove to be still alive, and longevity has begun to endow them with wisdom far greater than that which "short livers" can enjoy. Shaw's drawing out of this theme into a long dramatic sequence is an astonishing feat, and its conclusion, in A.D. 31,920, has an impressiveness wholly unexpected in a work of speculative fantasy.

"Saint Joan."—Shaw remained vigorously and variously productive into his 90s. Only one more play, however, is to be counted among his best, and it is generally regarded as his greatest. *Saint Joan* (1923; publ. 1924) achieves what he had always sought (and had most nearly achieved in *Caesar and Cleopatra* and *Major Barbara*): the fusion of high seriousness with high comedy. The life and death of Joan of Arc are made to typify a perennial conflict between human institutions and human inspiration. And Shaw is absolute for the inner voice of the individual as the instrument through which evolutionary change accomplishes itself in the world as we know it. The strength of his conviction about this makes Joan the strongest and most moving of his characters.

Prose.—Shaw was from the first concerned to make his plays readable, believing that they would best make their way on the stage if widely known in published form. For all of them, therefore, he wrote unusually full "stage directions"; and, for nearly all, long polemical prefaces. He was a master alike of dramatic and nondramatic prose, and the prefaces are inferior to the plays only as a good parliamentary speech must necessarily be inferior to an equally good parliamentary debate. On the stage Shaw contrives the effect of seeing fair play all round; characters relegated to upholding the most absurd intellectual positions are endowed with pungent powers of repartee. The incidence of what he declared to be his master formula—"Find the right thing to say, and then say it with the utmost levity"—sometimes bears too heavily upon the prefaces to make for good persuasive writing on serious topics. But some of them are masterly. And *The Intelligent Woman's Guide to Socialism and Capitalism* (1928; new ed., 2 vol., 1937, with chapters on Sovietism and Fascism), his most sustained nondramatic work, is a vigorous, lucid, and in places eloquent book, such as could have been written only by a mature master of English prose.

S.)

SHAW, HENRY WHEELER: *see* BILLINGS, JOSH.

SHAW, LEMUEL (1781–1861), chief justice of the supreme judicial court of Massachusetts from 1830 to 1860, who left an indelible mark on the law of the commonwealth and significantly contributed to the structure of American law. Born on Jan. 9, 1781 at Barnstable, Mass., he was educated at Harvard, studied law with David Everett, and was admitted to the bar in 1804. While a practitioner and Federalist officeholder in Boston he had extensive experience with public affairs, and was counselor to many ascendant industrial interests.

Respectful of the legislative will when statutes made it clear, Shaw did not hesitate to mold the common law to meet the needs of a changing society. He made the fellow-servant rule a principle of American law (*Farwell* v. *Railroad*, 4 Metcalf); he freed unions from the abusive application of the law of conspiracy (*Commonwealth* v. *Hunt*, 4 Metcalf); and, though opposed to slavery, he denied that racial segregation in public schools created unconstitutional inequalities (*Roberts* v. *Boston*, 5 Cushing). He died in Boston on March 30, 1861.

Shaw was closely associated with the family of Herman Melville, whose father-in-law he became. At the age of 21 Shaw was engaged to Nancy Melville, the author's aunt, but she died before they could be married. He maintained his relationship with her family after his marriage to Elizabeth Knapp in 1818; the Shaws' only daughter, Elizabeth, was married to Herman Melville in 1847.

See F. H. Chase, *Lemuel Shaw . . .* (1918); L. W. Levy, *The Law of the Commonwealth and Chief Justice Shaw* (1957). (M. DEW. H.)

SHAW, SIR (WILLIAM) NAPIER (1854–1945), English meteorologist, whose scientific contributions bridge the transition from the 19th-century era to the rejuvenated state of meteorology resulting from the ideas of the Norwegian School, as represented

by the work of V. and J. Bjerknes and their colleagues, after World War I, and from the direct analysis of the upper air. Born March 4, 1854, at Birmingham, he began his career teaching physics at Cambridge, where he had been a student, a task he performed with distinction for more than 20 years. Elected a fellow of the Royal Society in 1891, he was called from Cambridge in 1900 to become secretary of the Meteorological Council, which was the governing body of the Meteorological Office. His influence led to the reorganization, with noteworthy improvements, of the Meteorological Office. In 1905 he became director of the office, serving until his retirement in 1920. He then was named the first professor of meteorology at the Royal College of Science of the Imperial College of Science and Technology, retiring in 1924. Subsequently he devoted his attention to international meteorological affairs and to completing his four-volume *Manual of Meteorology* (1926–31). He died in London, March 23, 1945.

(H. R. B.)

SHAW, RICHARD NORMAN (1831–1912), British architect who played an important role in the Domestic Revival of the second half of the 19th century in England, was born in Edinburgh, Scot., on May 7, 1831. After an apprenticeship to William Burn, Shaw attended the architectural schools of the Royal Academy, winning a traveling scholarship to Germany, Italy, and France. He subsequently entered the office of G. E. Street. His early works were in collaboration with W. E. Nesfield. In his reaction against High Victorian Gothic, Shaw adopted divergent manners (often simultaneously), including neo-Baroque (Piccadilly Hotel, London, of 1905–08), but it was in the sphere of town and country houses that his influence was strongest and his style appears most characteristically: the former rely primarily on Shaw's very individual adaptation of the Queen Anne style; the latter derive from a study of regional developments in the English manorial style of the 16th century, and are carried out with a marked respect for the differing nature of different materials. The publication of Shaw's designs carried his influence outside England and was an element in the development of the American Shingle style.

Shaw's country houses are widespread. Characteristic examples are Wispers in Sussex (1875) and Adcote in Shropshire (1877). Town houses are best seen in London at Kensington, Chelsea, and Hampstead. In the field of town planning, the "Garden Suburb" laid out by Shaw in 1876 at Bedford Park (on the western side of London) was an important pointer to future developments of this nature. Shaw died in London on Nov. 17, 1912.

Bibliography.—Sir R. Blomfield, *Richard Norman Shaw, Architect* (1940); N. Pevsner, "Richard Norman Shaw" in *Architectural Review*, lxxxix (1941); H. R. Hitchcock, *Architecture: Nineteenth and Twentieth Centuries* (1958).

SHAWINIGAN, previously called Shawinigan Falls, is an industrial city in St. Maurice County, Quebec, Can., on the right bank of the St. Maurice River, 20 mi. above Trois-Rivières. Pop. (1961) 32,169. The falls near the city drop 165 ft. and 416,000 h.p. have been developed in two plants, supplying power both locally and to Montreal and Quebec. In 1901 an aluminum smelter, and a pulp and paper mill were installed in the village of Shawinigan Falls, forming the basis for its considerable industrial expansion. Other industries produce chemicals, abrasives, and textiles. The city is divided into two residential areas by the industrial belt and railway lines of Canadian Pacific and Canadian National railways. In 1961, 96% of the population was French-Canadian and 98% Roman Catholic. Shawinigan South, on the left bank of the St. Maurice River, had 12,683 persons in 1961. Shawinigan was incorporated as a village in 1901, a town in 1920, and a city in 1921. The name is the Algonkin word for "crest," used as a place name because the portage beside the falls of the river led over a crest of rocks. (M. C. Ba.)

SHAWL, a term applied to a square, oblong, or triangular article of dress worn as a protective or ornamental covering over the shoulders, neck, or head. It is found as clothing in most parts of the world. The word is of Oriental origin deriving from the Persian *shal.* Records seem to indicate Bukhara as the birthplace of the shawl-weaving industry. Shawls have been worn since the earliest times but the 19th century is known as the "shawl period" because then the shawl reached such a height of popularity that it became a necessity in the wardrobe of every woman in western Europe and America.

The first of the handsome Oriental shawls appeared in Europe after the Egyptian campaign in 1798. The most beautiful import was the Cashmere shawl produced in the valley of Kashmir in India. There the Tibetan goat produced a long fine fleece called pashm, which was softer than any wool known. The wool was woven into shawls by expert weavers trained for generations to a sensitive feeling for design and glowing colour. There are two types of Cashmere shawls, the woven shawl and those embroidered in imitation of weaving. In shape they were both square and oblong. The characteristic design was always the "cone" pattern inspired by the jeweled ornament in the turban of the Mughal emperors.

The Paisley shawl, machine produced in Scotland to meet the demand for the Cashmere, was an adaptation rather than an imitation of the Oriental shawl. Scarves, boas, mufflers, stoles, and smaller shawls are forms of the shawl popular as articles of dress in the 20th century.

(M. B. K.)

SHAWM (from the Latin *calamus,* a reed; Old French *chalemie*), a wind instrument of Near-Eastern origin, a precursor of the oboe. Like the oboe, the shawm is conically bored and sounded with a double reed of cane. Bore, bell, and fingerholes are, however, wider than the oboe's and the tone, intended for the open air, is of great power.

The shawm first appeared in the Near East about the beginning of the Christian era. It was later widely disseminated by Islamic influence, and numerous Oriental varieties are still played in many countries from Morocco to China. At the time of the Crusades the shawm was introduced into Europe and became widely used for dance and ceremonial music. In the 16th century shawms were constructed in various pitches from treble to great bass, the larger sizes being known in French as *bombardes* and in German as *Pommern.* The shawm was rarely used in Europe after the 17th century, but in Spain it survived as the *tiple* (treble) and *tenora* (tenor) which, modernized with complete keywork, still lead the bands for the sardana, the national dance of Catalonia.

(A. C. Ba.)

SHAWN, TED (Edwin M.) (1891–), U.S. dancer, choreographer, and dance educator who significantly increased the stature of the American dance and the respect accorded to it especially as a career for men, was born in Kansas City, Mo., on Oct. 21, 1891. He was originally destined for the ministry, but turned his attention to the dance after a serious illness interrupted his studies. He was just beginning his career when in 1914 he met and married Ruth St. Denis (*q.v.*), with whom he founded the Denishawn School, where every dance technique was taught, and the Denishawn Dancers, a troupe which toured extensively in the United States and visited the Orient in 1925–26.

From 1933 to 1940, after his separation from St. Denis, Shawn devoted himself to building a group of men dancers that presented such impressively masculine works as *Labor Symphony, Olympiad* and *Kinetic Molpai.* He next developed the Jacob's Pillow Dance Festival (Lee, Mass.), which was modestly inaugurated in 1933; under Shawn's leadership it became a dance centre of international importance, with its own school and theatre. Shawn also wrote and lectured extensively.

See Katherine S. Dreier, *Shawn, the Dancer* (1933), and the chapter on Shawn in Walter Terry, *The Dance in America* (1956). (Ln. Me.)

SHAWNEE, an Algonkian-speaking Indian tribe that lived in the central Ohio Valley until the 17th century, when they were driven out by the Iroquois and scattered into widely separated areas. Some settled in what is now Illinois and others in the Cumberland Valley, while one group moved to the southeast, giving its name to the Savannah River. After 1725 the tribe united again in the region of Ohio, where they formed the principal barrier to the advance of U.S. settlers. Following their defeat by

Gen. Anthony Wayne (*q.v.*) at the Battle of the Fallen Timbers, and the failure of Tecumseh (*q.v.*) to unite the Indians of the Ohio Valley, they broke into three independent branches (Absentee, Eastern, and Cherokee Shawnee) that eventually settled in different parts of Oklahoma.

Closely related in language and culture to the Sauk, Fox Indians (*qq.v.*), and Kickapoo, the Shawnee were also influenced by their long association with the Seneca and Delaware Indians (*qq.v.*), and combined eastern woodland and prairie traits. During the summer they lived in bark-covered houses grouped into large villages where women raised corn while men hunted; in winter, small family groups realigned themselves into hunting camps. Each village had a large council house that was also used for such religious ceremonies as the ritual purification of warriors. Other important ceremonies included the spring Bread Dance held when the fields were planted; the Green Corn Dance marking the ripening of crops; and the autumn Bread Dance. The social organization included patrilineal clans and an Omaha type of kinship system based on the lineage principle (*see* KINSHIP TERMINOLOGY). Early Shawnee population was estimated at 2,000 to 3,000; in the 1960s the three main settlements in Oklahoma numbered about 2,250.

SHAWNEE, a prairie city of central Oklahoma, U.S., on the North Canadian River, 38 mi. ESE of Oklahoma City; the seat of Pottawatomie County. It was named for the Shawnee Indians who came west after the defeat of Tecumseh in 1812, joined the Potawatomi, and in 1867 were brought into the Indian Territory. In 1891 their land was opened to white settlement. The city, originally known as Shawnee Town because it was a trading place for Indians, was incorporated in 1894 as Shawnee. Farming, stock raising, oil, and diversified industries are the bases of its economy. Educational facilities include St. Gregory's College, a Roman Catholic institution for men established in 1915, a two-year college with a three-year professional school (noted for its museum and library), and Oklahoma Baptist University, a four-year coeducational institution established in 1911. Places of historical interest include the Quaker Mission Church, established in 1872.

For comparative population figures *see* table in OKLAHOMA: *Population*. (AN. L.)

SHCHERBATSKY, FEDOR IPPOLITOVICH (1866–1942), Russian philologist, whose works on Buddhist logic and philosophy became known as authoritative and valuable, was born in St. Petersburg on Oct. 1 (new style; Sept. 19, old style), 1866, of a family of old nobility. He was educated at Tsarskoe Selo and studied philology at St. Petersburg, Vienna, and Bonn. In 1904 he became professor of Indian literature at St. Petersburg. He spent a few years in Mongolia and India and selected for special study Buddhist logic and metaphysics. He was greatly influenced by Dharmakirti's logical work, of which he published a translation with a detailed commentary. His chief works are *Logic in Ancient India* (1902); *Buddhist Philosopher on Monotheism* (1904); *Theory of Knowledge and Logic According to the Later Buddhists* (part i, *Text Book of Logic* by Dharmakirti; part ii, *Study of Perception and Deduction* [1909]); *Study of the Categorical Imperative Amongst Brahmans* (1918); *The Conception of Buddhist Nirvana* (1927); and *Buddhist Logic*, two volumes (1930–32). He also published many Sanskrit manuscripts in the *Bibliotheca Buddhica* of the Academy of Sciences. He died on March 18, 1942. (S. RA.)

SHEARING MACHINES: *see* MACHINE TOOLS.

SHEARS: *see* SCISSORS AND SHEARS.

SHEARWATER, any of 40 or so medium-sized plainly coloured petrels (*q.v.*), chiefly of the genera *Puffinus* and *Pterodroma*. Most species nest in the southern hemisphere; a few, such as the sooty shearwater (*Puffinus griseus*) and the greater shearwater (*Puffinus gravis*), reach the shores of the northern hemisphere on their migrations. The Manx shearwater (*P. puffinus*) nests on the coasts of Europe. Shearwaters spend the greater part of their lives on the ocean. The single white egg is laid in a hole underground. The young are thickly covered with long down and become extremely fat. In this condition they are considered good eating, and enormous numbers are caught in some localities, especially on islands off Australia, where they are known as muttonbirds. (DN. A.)

SHEATHBILL, a bird so called from the horny case around the base of its bill. There are two species, constituting the family Chionididae. They are found only in the antarctic regions.

The sheathbills are about the size of a pigeon, which they resemble in many ways. The plumage is white. In the white sheathbill (*Chionis alba*) the bill is yellowish at the base, becoming pale pink toward the tip; the skin around the pink-rimmed eyes bears cream-coloured pimples; and the legs are bluish gray. The lesser sheathbill (*Chionis minor*), only slightly smaller than the white sheathbill, has a dark bill and legs and a differently shaped "sheath." The white sheathbill collects its food, consisting of seaweeds and shellfish, on rocks at low tide; it is also known to eat birds' eggs. Though most commonly encountered as a shore bird, it can be seen far out at sea. The eggs of both species are not unlike those of oyster catchers.

SHEBA (SABA): *see* SABAEANS.

SHECHEM (SICHEM), a city of ancient Palestine, 8 mi. SE of Samaria. It is now a large mound called Balatah about 1½ mi. E of Nablus (Roman Neapolis) in western Jordan, in the valley between Mt. Ebal and Mt. Gerizim. A few hundred yards from Balatah toward the adjacent alluvial plain are the traditional sites of Jacob's well and of the tomb of Joseph. Since the mound, despite its extent, had been almost buried by the earth and stones washed down from the mountains, it was not identified with Shechem until shortly before World War I, when Ernst Sellin recognized its significance and led a German expedition to open it up (1913–14 and 1926–34). The excavations of Sellin, followed after 1928 by G. Welter and H. Steckeweh, unearthed a massive pre-Israelite city wall, two monumental city gates, a citadel with a massive Canaanite temple and other important remains. Most of the German work was done before the chronological value of pottery was generally accepted, so the direct historical results were somewhat meagre. In 1956 excavations were resumed by a U.S. expedition headed by G. E. Wright and B. Anderson. By means of modern pottery chronology, the history of the site has been worked out in detail. Combined with the information from Egyptian and cuneiform inscriptions, as well as with biblical and Greco-Roman data, the archaeological finds on the site yield a fairly complete picture from *c.* 2000 B.C. down to the destruction of the old city in the late 2nd century B.C. During the first centuries A.D. a village occupied part of the site.

By the time of the Egyptian middle kingdom (*c.* 2000–1800 B.C.) Shechem was one of the most important towns of the Palestinian hill country, as shown by references to it as a focus of actual or feared rebellion. It must already have been a leading centre for trade and communication because of its position at the southeastern edge of the Nablus pass, which led directly across the watershed ridge of western Palestine. When the Hyksos were ruling in Egypt, Shechem became a stronger fortress than any yet excavated in Palestine. Its importance in Hebrew tradition of the early 2nd millennium B.C. is illustrated by numerous references to it in connection with the stories of Abraham and Jacob (*e.g.*, Gen. 12:6; 33:18). In the 15th–14th centuries B.C. the population was already very mixed, as shown by the personal names in cuneiform tablets from the Shechem area found at Tell el Amarna in Egypt as well as at Balatah itself. Horites (so read in Gen. 34:2, with the Greek translation, instead of "Hivite") and Indo-Aryans lived at Shechem together with Hebrews and other Semites. In the early 14th century B.C. a chieftain with the good Hebrew name of Lab'ay ("lion-man") ruled the Shechem district. In the Amarna tablets the Hebrews (Apiru) are said to have been in control of the town. (In Gen. 34 the house of Jacob is said to have conquered Shechem.)

Shechem was not destroyed at the time of the Israelite occupa-

tion of the rest of the hill country of Palestine, and in the time of Joshua it became (together with Shiloh) the chief meeting place for representatives of the tribal confederacy (Josh. 24:1). In the early 11th century it was briefly the capital of the ephemeral monarchy set up by Abimelech (Judg. 9), and Jeroboam made it the first capital of the northern kingdom (I Kings 12:25) in the 10th century. After the exile it became the religious capital of the Samaritan sect, which replaced Jerusalem by Gerizim as its holy mountain. About 130 B.C. it was occupied by the Hasmonaean king John Hyrcanus I, and it never recovered its importance.

(W. F. A.)

SHEEP. Sheep belong to the family of hollow-horned ruminants or Bovidae (*q.v.*). They pass almost imperceptibly into the goats. Both sexes often possess horns, but those of the females are small. In the males the horns are generally angulated, and marked by fine transverse wrinkles; their colour is greenish or brownish. They are directed outward, and curve in an open spiral with the tips directed outward. Although there may be a fringe of hair on the throat, the males have no beard on the chin; and they also lack the strong odour characteristic of goats. Usually the tail is short; and in all the wild species the outer coat takes the form of hair, though beneath lies a short undercoat of fine wool which has been developed into the fleece of domesticated races. Weight varies from somewhat less than 100 lb. to several hundred pounds.

Like goats, sheep have narrow upper molar teeth, very different from those of the oxen, and narrow hairy muzzles. Between the two middle toes, in most species, is lodged a deep glandular bag, having the form of a retort with a small external orifice, which secretes a strong-smelling, oily substance. This, tainting the herbage or stones over which the animal walks, affords the means by which, through the powerfully developed sense of smell, the neighbourhood of other individuals of the species is recognized. The crumen, or suborbital face gland, which is so largely developed and probably performs the same office in some antelopes and deer, is present, although in a comparatively rudimentary form, in most species, but is absent in others. It may be added that the long tails of most tame breeds are, like wool, in all probability the results of domestication.

Origin and History.—The bones of sheep are found with other evidences of early human habitation at sites ranging from the Middle East to the crannogs of Ireland. Remains at Hassuna in upper Mesopotamia and at Sialk in central Iran are indicated as very early sites. But archaeological evidence presumably accumulated considerably later than domestication took place, for the Neolithic period appears to have opened with a well-established agriculture and a rather full complement of crops and animals which are still basic to farmers. Other evidence, particularly that from religious history, also suggests early domestication—the sheep is the preferred animal for sacrifice in ancient as well as some modern religious ceremonials.

Carl O. Sauer, author of *Agricultural Origins and Dispersals* (1952), associated domestication of sheep not with hunters or nomads but with sedentary seed farming, with southwest Asia indicated as the most probable hearth of domestication. Leopold Adametz, Austrian livestock-research specialist, associated an early domestic form with spiral horns with a variety of the urial (*Ovis vignei*) living from the Salt Range of the Punjab to Baluchistan, whence they passed to the Near East and beyond. In the Copper Age a new breed (*O. aries studeri*), with massive spiral horns, appeared in Europe, and J. U. Duerst, Swiss animal geneticist, showed that it was almost certainly derived in part at least from the wild mouflon (*O. musimon*). In Sardinia, as has been known since the time of Pliny, the mouflon interbreeds freely with domesticated sheep. The bulk of modern breeds are obviously much more closely related to the sheep of the Copper Age than to the earlier type; while it thus seems likely that the mouflon played the major part and the urial a minor part in producing farm flocks, it is by no means certain that other species, such as the argali (*O. ammon*), were not concerned.

VARIETIES AND DISTRIBUTION

Wild Sheep.—Wild sheep attain their maximum development both in number and size, in central Asia. They associate either in large flocks or in family parties, the old males generally keeping apart from the rest. Although essentially mountain animals, sheep generally frequent open, undulating districts rather than the precipitous heights to which goats are partial.

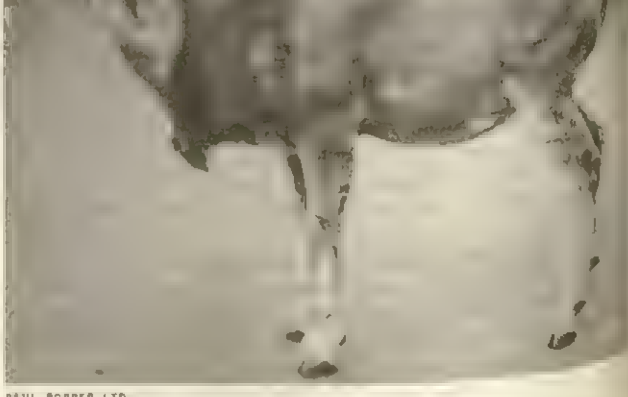
The Pamir Plateau, on the confines of Turkistan, at an elevation of 16,000 ft. (4,900 m.) above sea level, is the home of the magnificent *Ovis poli*, named after the celebrated Venetian traveler Marco Polo, who met with it in the 13th century. It is remarkable for the great size of the horns of the old rams and the wide open sweep of their curve, so that the points stand boldly out on each side, far away from the animal's head, instead of curling round nearly in the same plane, as in most of the allied species. A variety inhabiting the Tien Shan range is known as *O. karelini*, and other forms occur in the mountains and lower ground of Turkistan and in central Asia.

An even larger animal is the argali (*O. ammon*), typically from the Altai range but represented by one race in Ladakh and Tibet, by a second in eastern Mongolia, and by a third in the Gobi Desert. The largest living wild sheep, it may stand four feet high at the shoulders and weigh over 300 lbs. (136 kg.). Although its horns are less extended laterally than those of the Marco Polo sheep, they are grander and more massive. In their short summer coats the old rams of both species are nearly white. Closely allied forms are found in the Sair Mountains and Kulja.

In the Stanovoi Mountains and neighbouring districts of east Siberia and in Kamchatka occur two sheep which have been respectively named *O. borealis* and *O. nivicola*. They are, however, so closely allied to the bighorn (*q.v.*) or mountain sheep of North America that they can scarcely be regarded as more than local races. These bighorns are characterized by the absence of face glands and the comparatively smooth front surface of the horns of the old rams, which are thus very unlike the strongly wrinkled horns of the argali group.

The typical bighorn is the khaki-coloured and white-rumped Rocky Mountain animal; but on the Stikine River in British Columbia there is a nearly black race, with the usual white areas, while this is replaced in Alaska by the nearly pure-white Dall sheep, the gray sheep of the Yukon being perhaps not a distinct form. Other geographical races of the bighorn, distinguished chiefly by the colour of the coat, include the mountain sheep of Mexico, of Lower California, and of the Kenai Peninsula of Alaska.

Returning to Asia, in Ladakh, Afghanistan, and the Punjab



PAUL POPPER LTD.

URIAL OR WILD SHEEP OF THE PUNJAB

ranges is found the sheep whose local races are variously known as urial, urin, and shapo, which has tightly curved horns. It is a smaller animal than the members of the argali group, and approximates to the Persian and Armenian moufion (*O. orientalis*) and the Sardinian and Corsican mouflon (*O. musimon*), and on Cyprus a small race (*O. orientalis ophion*) hunted almost to extinction. Mouflon rams carry good, widely curving horns. In Tibet is the bharal (*Pseudois nahura*), the wild blue sheep of the Himalayas. They live in bands of 10 to 50 in mountain meadows above 10,000 ft. (3,050 m.). The ram is characterized by a black band separating the blue-gray back from the white underparts, and by smooth sigmoid horns sweeping backward in a semicircle. The udad, aoudad, or audad (*Ammotragus lervia*), the Barbary sheep, is the only sheep native to Africa, where it inhabits the mountain ranges of the north, descending eastward far into the Sudan. It is distinguished by long, abundant hair on the throat and forequarters of the rams. Both the bharal and the udad have no face glands, and in this and their smooth horns approximate goats. Additional information on varieties and distribution of wild sheep will be found in the separate articles on various countries and areas. (*See* also HUNTING: *Big Game Hunting*.)

(R. LY.; J. RI.; J. K. R.)

Domestic Sheep.—Domestic sheep differ from their wild progenitors and even among themselves in conformation, quantity, and quality of fleece, colour, size, milk production, and other characteristics. Breeds of sheep have been developed to meet environmental conditions influenced by latitudes and altitudes and to satisfy variable desires of the people for clothing and food. The commodities for which sheep have been bred include wool, fur, meat, and milk.

Of more than 200 breeds of sheep in existence in the world, the majority are of limited interest, except in the localities where they are raised. About 30 of the breeds which are most extensively raised or have otherwise attained prominence provide the principal basis for this discussion. They may be grouped into the following six types according to the kind and quality of commodities which they produce:

Fine-wool type.—Merino and Rambouillet.

Medium-wool type.—White-face sheep—Cheviot, Columbia, Corriedale, Dorset, Ile de France, Le Cotentin, Montadale, No-Tail, Oldenburg White Head, Panama, Romeldale, Ryeland, Targhee, Texel, and Welsh Mountain; dark-face sheep—Hampshire, Kerry Hill, Oxford, Shropshire, Southdale, Southdown, and Suffolk. Except for the Kerry Hill, these dark-face sheep are also called Down sheep, as they originated in the Downs of England and may have been the native sheep of the open-field farmer. The Tunis, whose modern native home was north Africa, has a brown face.

Long-coarse-wool type.—White-face sheep—English Leicester, Border Leicester, Cotswold, Lincoln, Romney, and Wensleydale; dark-face sheep—Blackface Highland of Scotland. The progenitors of these breeds, especially the Lincolns and the Romney Marshes, were probably of Flemish origin.

Fur type.—Karakul and Romanov.

Woolless mutton type.—Blackhead Persian.

Milk type.—East Fresian, La Razza Sarda, Pelvin, Sevlievo, Stara Zagora, and Svishtov.

Brief descriptions of these breeds follow.

Breeds of Sheep.—The Merino, a fine-wool sheep, originated in Spain. It was known as early as the 12th century and may have been a Moorish importation. It was particularly well adapted to semiarid climates and to transhumance. It became a prominent breed in many countries, notably Australia, the United States, the Union of Soviet Socialist Republics, South Africa, Argentina, France, and Germany. This breed has been designated by various names such as Australian Merino in Australia, American Merino and Delaine Merino in the United States, Merino Transhumante in Spain, Merino Volosh, the Soviet Merino, Ascanian, Caucasian, and Altai in the Union of Soviet Socialist Republics, Merino Argentino in Argentina, Merino Precoce in France, and Thuringia Merino-Meat in Germany. Some of these names signify strains of the parent breed that have been modified by selective mating, but all the sheep have rather heavy fleeces of fine wool that is pure white when scoured.

Merinos vary considerably in size, conformation, and extent of skin folds, but the prevailing trend in breeding is to develop sheep of medium size, fair mutton conformation, and freedom from excessive skin folds. The colour of their faces and legs is white. Although they have a considerable growth of wool on their faces, it is seldom extensive enough to cause wool blindness. The fine wool fibres of Merino fleeces are beautifully crimped and the fleeces have a tendency to carry sufficient natural fat to keep the fibres of the inner part of the fleeces soft and pliable. The fat in combination with the dust and soil of natural surroundings forms a dark covering on the outer part of the fleece that protects the beautiful, fine, white wool fibres of the inner portion. Through selective mating and crossing with other breeds, the Merino has served extensively as foundation stock in the creation of many useful breeds and strains of sheep. Of the four Merino types which became widely known and provided the basis for the expansion in apparel wool production in the 19th century, the heavily wrinkled Negretti became the basis for most of the English Merino development. The small, tighter-skinned Escurial appears to have been basic to the Rambouillet and Saxon developments, whereas the Paular and Infantado appear to have participated only slightly. After World War II considerable interest developed in Australia in polled Merino.

The Rambouillet, also a fine-wool sheep, originated in France. It was developed from excellent selections in 1786 and again in 1799 of a few hundred of the best Merino sheep in Spain. The French government made these selections and placed the flock at its national sheepfold, Rambouillet, France, where this breed originated. It is the largest of fine-wool sheep. Breeders in Germany made important contributions to the development of the Rambouillet, especially to its fleshing qualities.

Sheep of this breed were first imported into the United States in 1840. Through selective mating the breed was successfully molded to meet the needs of a large class of U.S. sheep producers. Rambouillets prevail on the western ranges where two-thirds of the sheep of the United States are produced. The face and legs of this breed are white. The face covering of wool is rather heavy, even to the extent of wool blindness in some specimens, but through selective mating breeders have made progress in developing strains free from such excessive face covering. Fleeces of Rambouillet sheep are relatively heavy. The lambs grow rapidly, attaining under good feed conditions satisfactory market weights, and finish at from six to nine months of age. The crossbreeding of Rambouillet ewes with medium-wool and long-coarse-wool rams is practised extensively for the production of choice market lambs and of rugged breeding ewes that produce heavy fleeces of attractive medium wool.

The Cheviot is a medium-wool breed. It is a hardy, white-face, hornless sheep developed in Scotland and Northumberland, Eng. Cheviots have no wool on their heads and ears or on their legs below the knees and hocks. As a consequence they present an attractive and alert appearance. The wool of their fleeces is relatively straight, of moderate length, close set, and free from black fibre. Cheviots are used in crossbreeding, especially with Border Leicesters and Lincolns, for market lambs.

The Columbia is a medium-wool, white-face, hornless breed developed in the United States by the U.S. Department of Agriculture. It was formed by crossbreeding Lincoln rams and Rambouillet ewes and interbreeding the resulting crossbred ewes and rams and their descendants without backcrossing to either parent stock. The initial crossbreeding began at Laramie, Wyo., in 1912, and after 1918 the molding of the breed was carried out at the United States sheep experiment station, Dubois, Ida. The sheep of this breed are large and rugged, and they excel in the production of both wool and lambs. The breed is popular, especially in the western U.S. range region, where private breeders organized the Columbia Sheep Breeders' Association.

The Corriedale is also a medium-wool, white-face, hornless breed. It originated in New Zealand as a result of crossbreeding Lincoln rams and Merino ewes, beginning about 1880. The breed is valued especially in New Zealand, Australia, and the United States. Corriedales are of medium size, and they produce wool and lambs of very good quality. The breed is adapted to both farms and ranges.

The Polwarth is an A[illegible] was developed in Victori[illegible] rather large sheep which [illegible] from crosses of Merino and Lincoln. Less numerous than Merino or Corriedale, it still is important in the Australian sheep industry in localities too cold and wet for Merino.

The Romeldale is a medium-wool, white-face, hornless sheep of the western United States, especially raised in California. It resulted from the crossbreeding of Romney rams and Rambouillet ewes, beginning about 1915. It is well suited to pasturage of alfalfa and heavy forage, as well as being hardy and well suited to range conditions. The Romeldale produces wool and lambs of high quality.

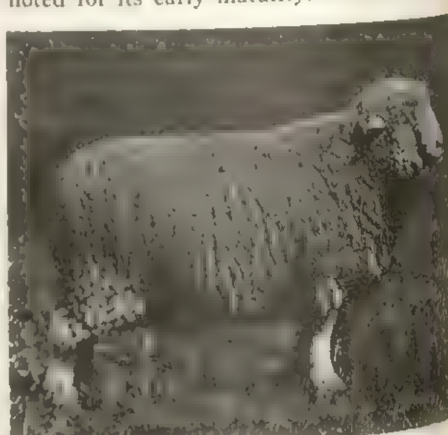
The Ryeland is a medium-wool, white-face, hornless sheep of England. The lambs grow quickly; the wool is good quality, of deep staple, and thickly set on the skin. Sheep of this breed were raised to some extent in the United States, especially in Kentucky.

The Targhee was developed at the U.S. experiment station at Dubois, Ida., after 1926 by vigorous selection and inbreeding of various Rambouillet-Columbia-Corriedale combinations to produce a true-breeding strain intermediate to the smaller fine-wool breeds and the large crossbreeds. Hardy and of medium size, it is well adapted to the range; it is of compact conformation with a moderately low-set, broad, level back, good bones, and straight legs. The rump and leg of mutton are well developed. The fleece is heavy, of desirable fineness (60s and 62s) and staple length. Ewes are good mothers and handle easily; necks are without folds and faces are open.

The Texel is a medium-wool, white-face, hornless sheep of the Netherlands, well adapted to range conditions and very prolific. The lambs grow rapidly. The fleeces of this breed are of good, heavy, white wool. The Texel is raised also in France, Belgium, Denmark, Spain, Indonesia, South America, South Africa, and Mexico.

The Welsh Mountain is a medium-wool, white-face sheep of Wales, and is of importance in other parts of the United Kingdom. The rams have horns and the ewes are hornless. It is noted for its very high-quality mutton. The fleeces are light in weight but of good quality.

The Hampshire is a medium-wool, dark-face, hornless sheep that originated in England. It is large and blocky and, as a superior mutton breed, is noted for its early maturity. It is one of the



TARGHEE RAM

BORDER LEICESTER EWE

PHOTOS COURTESY OF THE U.S. DEPARTMENT OF AGRICULTURE

most popular meat breeds in the United States, where it is raised extensively for market-lamb production in farming regions and for crossing with white-face range ewes in the western range regions for the production of market lambs. The wool of Hampshire fleeces is strong, of medium fineness and length, and desirable for manufacturing purposes except for the occurrence of black fibres in a small percentage of fleeces.

The Kerry Hill is a medium-wool, hornless sheep with markings that consist of black speckles on white faces, ears, and legs. It originated in the British Isles and is a hill sheep that combines desirable features of the Hill and Down types. Its fleece resembles that of the Shropshire but is not so good in quality. It produces good mutton and is excellent for crossbreeding.

The Oxford is a medium-wool, dark-face, hornless sheep, and it is the heaviest of the Down breeds. It was produced by mating Hampshires and Cotswolds in Oxfordshire, Eng. The ewes are good mothers and the lambs grow rapidly. Their fleeces are heavy and the wool is of good length for sheep of the medium-wool type. They are popular on farms that have abundant feed. Considerable numbers are found in England and the Great Lakes region of the United States.

The Shropshire is a medium-wool, dark-face, hornless breed that originated in the Downs of England. It is one of the most popular farm sheep in middle-western United States. It produces good wool and mutton and subsists on sparse pasturage better than breeds such as the Hampshire or Suffolk. For crossbreeding it is better adapted to farms than to range conditions. Its face covering of wool is excessive, which is more easily dealt with on farms.

The Southdale is a breed resulting from crossing the Southdown and the Corriedale.

The Southdown is a medium-wool, dark-face, hornless sheep. It is a Down breed that was raised on the Sussex hills of England. The Southdown is the oldest of all British breeds of sheep, and it has an ideal body conformation for meat production. Its fleece is close and the finest of the British breeds; but although white and of good quality, the wool is short and the fleeces relatively light in weight. The colour of its face and legs is brown to light brown or mouse colour. Southdowns are popular in many parts of the world, especially in Commonwealth of Nations countries and the United States.

The Suffolk is a medium-wool, dark-face, hornless sheep. It was developed in England by mating Norfolk horned ewes with Southdown rams during the years 1800 to 1850. Suffolks are prolific, early maturing sheep with excellent mutton carcasses. They are energetic and the whole carriage is alert, showing stamina and quality. Suffolk lambs gain rapidly and the breed is noted for mutton production. This breed is not desirable for wool production. The fleeces are short in staple and light in weight, and they have black fibres. Suffolks are popular as lamb producers.

The Tunis, a medium-sized to small, polled, coarse- to medium-wool breed, was imported into the U.S. from north Africa as early as 1799. Early grown in the southeast, they are now largely produced in the New York to Indiana section, where they are renowned for mating during all seasons, thus favouring the off-season milk lamb industry.

The Zenith is an Australian-bred sheep, founded at "Trelawney," Donald, Victoria, that came into prominence after World War II. The breed was considered fixed in 1947, when it was named. A dual-purpose comeback sheep (Merino crossed with an English breed and crossed back to Merino), it is rather large, with a dense fleece.

The English Leicester is a long-coarse-wool breed that originated in England through improvement by the noted breeder, Robert Bakewell, about 1755. This breed has white faces and legs. They are hornless, broad-backed, thick-fleshed, and early maturing. Their fleeces are heavy, with a tuft on the forehead and wool hanging in compact locks on the body. Some of the choicest wool of crossbred sheep is produced by offspring of Merino ewes and English Leicester rams.

The Border Leicester is a long-coarse-wool, white-face, hornless sheep that was developed in the border counties of England and Scotland by crossbreeding English Leicester and Cheviot sheep. The head is free from wool, bold and carried high. The whole carriage of this choice mutton body presents a square, alert, stylish appearance. The wool is long, soft, and in small locks, but fairly compact.

The Cotswold is a long-coarse-wool, white-face, hornless sheep that originated in England. The back is broad and flat, but the body is only moderate in depth. The fleeces are heavy and on the surface the wool lies in open curls. This breed is used successfully in crossing with Merinos and Rambouillets to increase size of body and length of wool fibre.

The Lincoln is a long-coarse-wool, white-face, hornless sheep, native of England. It is a large mutton sheep with heavy fleeces of tufted wool, and the poll is covered with wool. Rams of this breed are used extensively in many countries for crossbreeding with fine-wool ewes.

The Romney is a long-coarse-wool, white-face, hardy, polled sheep that originated in Kent, Eng. It is sometimes called the Kent or the Romney Marsh. Sheep of this breed are popular in South America, Australia, New Zealand, and in some western areas of the United States. Their fleeces are relatively dense and on the average are the finest of the long-coarse-wool fleeces. The rams are used rather extensively in the western U.S. for crossbreeding with Rambouillet ewes.

The Wensleydale is a long-coarse-wool, white-face, hornless breed of England. The wool is long, lustrous, and in wavy locks. The skin on the face, ears, and legs, and sometimes on the body, is of a bluish tinge. In England they are crossed with other long-coarse-wool breeds. Their mutton is of good quality, but they mature rather slowly.

The Blackface Highland is a long-coarse-wool, dark-face, horned, mountain sheep, native of Scotland. It is extremely hardy, matures quickly, and produces mutton of excellent quality. The wool of the fleeces of this breed is used extensively in the manufacture of tweeds, and the coarsest of it makes good, strong carpet wool.

The Karakul is a fur sheep, native of central Asia. Black is the prevailing colour of newborn lambs, which in most cases have beautiful tight-curled coats that, when skinned at about one to three days old, provide the commercial lambskin fur for which they are raised. A large percentage of the lambskins are classified by the trade as Persian lambskins. The wool of grown sheep is a mixture of coarse and fine fibres, of colours varying from black to various shades of brown and gray. The prevailing colour of the face and legs is black. The ewes are good mothers, and the lambs grow rapidly and produce good meat, but the breed is primarily intended for lambskin-fur production. Horned and hornless sheep occur in both sexes. Karakul sheep are raised in several countries of Asia, Europe, Africa, and the Americas.

The Romanov is a fur sheep of the Union of Soviet Socialist Republics, and it is found particularly in the Yaroslavl region. It is noted as a fur-producing sheep that excels in prolificacy. Black and white occur on face and legs and in the fibres of the fleeces.

The Blackhead Persian is a woolless fat-rumped sheep that has been highly developed for mutton production in South Africa, where it thrives on lands not well suited to wooled sheep. The head and neck are black and the body is white. This breed is indigenous to North Africa, Somaliland, and Arabia. The name "Persian" is misleading, for none of these sheep have come from Persia.

The East Fresian is a white-face milk sheep, native of Germany. It is considered to be one of the best milk breeds of sheep in Europe. In addition to its heavy milking qualities it is also well fleshed and wooled with heavy fleeces of white medium to coarse wool. The head is bare of wool and polled.

The La Razza Sarda is a milk sheep, native of Sardinia. The face is white with small black spots about the eyes and muzzle. It is noted as a heavy milk producer and also valued as a producer of long, white wool of coarse but good quality.

The Pelvin is a black-face milk sheep of Bulgaria, valued especially for milk production in one of the largest sheep-producing areas. It also produces a good weight of wool that is grayish in colour and medium to coarse in fineness.

MERINO RAM

MERINO EWE

The Dorset is a medium-wool, white-face sheep. Both ewes and rams have horns; the breed is sometimes called the Dorset Horn. It originated in England. The ewes are heavy milkers and their lambs grow rapidly. The fleece is pure white, rather short and open. The breed is valued also in the United States and other countries for the production of fancy hothouse lambs, as a portion of the ewes will breed out of season. They also cross well with Merinos for the production of crossbred ewes well suited to hothouse lamb production. Both Dorset Horns and polled Dorsets are bred in Australia.

The Ile de France is a medium-wool, white-face, hornless sheep that is an excellent producer of both meat and wool in France. It is especially noted for its early maturity and the rapid growth of its lambs.

The Le Cotentin is a medium-wool, white-face, hornless sheep of France maintained primarily as a grazing sheep. The ewes are good milkers and raise their lambs well. They have good conformation and their meat is of first quality. They are also good wool producers.

The Montadale, a medium-wool, medium-sized mutton sheep, was developed in the U.S. after 1932 from Columbia ewes and Cheviot rams.

The No-Tail, a medium-wool breed, has been developed since 1913 in South Dakota from Siberian, "fat-rumped" sheep, crossed with several fine-wool and medium-wool breeds.

The Oldenburg White Head is a medium-wool, white-face, hornless sheep of Germany, noted as a hardy grazing breed. It is very prolific and an excellent producer of both lambs and wool.

The Panama is a medium-wool, white-face, hornless breed of the western United States, originated in Idaho in 1912 by crossbreeding Lincoln ewes and Rambouillet rams. These sheep have good size, are hardy, and are well adapted to the range. The ewes are good milkers and raise their lambs well. Their fleeces of white wool are heavy.

The Polwarth is an Australian breed of rather large sheep which was developed in Victoria in the 1880s from crosses of Merino and Lincoln. Less numerous than Merino or Corriedale, it still is important in the Australian sheep industry in localities too cold and wet for Merino.

The Romeldale is a medium-wool, white-face, hornless sheep of the western United States, especially raised in California. It resulted from the crossbreeding of Romney rams and Rambouillet ewes, beginning about 1915. It is well suited to pasturage of alfalfa and heavy forage, as well as being hardy and well suited to range conditions. The Romeldale produces wool and lambs of high quality.

The Ryeland is a medium-wool, white-face, hornless sheep of England. The lambs grow quickly; the wool is good quality, of deep staple, and thickly set on the skin. Sheep of this breed were raised to some extent in the United States, especially in Kentucky.

The Targhee was developed at the U.S. experiment station at Dubois, Ida., after 1926 by vigorous selection and inbreeding of various Rambouillet-Columbia-Corriedale combinations to produce a true-breeding strain intermediate to the smaller fine-wool breeds and the large crossbreeds. Hardy and of medium size, it is well adapted to the range; it is of compact conformation with a moderately low-set, broad, level back, good bones, and straight legs. The rump and leg of mutton are well developed. The fleece is heavy, of desirable fineness (60s and 62s) and staple length. Ewes are good mothers and handle easily; necks are without folds and faces are open.

The Texel is a medium-wool, white-face, hornless sheep of the Netherlands, well adapted to range conditions and very prolific. The lambs grow rapidly. The fleeces of this breed are of good, heavy, white wool. The Texel is raised also in France, Belgium, Denmark, Spain, Indonesia, South America, South Africa, and Mexico.

The Welsh Mountain is a medium-wool, white-face sheep of Wales, and is of importance in other parts of the United Kingdom. The rams have horns and the ewes are hornless. It is noted for its very high-quality mutton. The fleeces are light in weight but of good quality.

The Hampshire is a medium-wool, dark-face, hornless sheep that originated in England. It is large and blocky and, as a superior mutton breed, is noted for its early maturity. It is one of the

SOUTHDOWN RAM

SOUTHDOWN EWE

RAMBOUILLET RAM

RAMBOUILLET EWE

CHEVIOT RAM

CHEVIOT EWE

The Sevlievo is a dark-face milk sheep of the mountain type, from Bulgaria. It is one of the more abundant milk-producing sheep and a fair producer of pigmented wool of medium fineness.

The Stara Zagora is a large, white-face, horned milk sheep of Bulgaria, developed for an abundance of milk but also valued for its white medium-wool fleece.

The Svishtov is a white-face, horned milk sheep of the region between the Danube River and the Balkan Mountains. It is noted for its abundant production of milk and for its good fleece of long, white, coarse wool. (D. A. S.; J. K. R.)

Improvement of Sheep.—The existence of more than 200 different breeds of sheep, differing in appearance as well as in function, indicates the variety of ideals held by breeders. It also indicates the wide range of genetic material available for experimentation. Unfortunately, most herdsmen in the past made little use of either line breeding or inbreeding to develop their flocks. By mid-20th century those techniques were utilized as well as progeny testing and some selection indexes and performance yardsticks. The use of artificial insemination has become more widespread, and breeding synchronization techniques employing steroid drugs to control the onset of estrus (and ovulation) have been developed. (*See* ANIMAL BREEDING.)

Most sheep are raised for two principal products, meat and wool. In the case of the Merino, the annual wool clip is more valuable to the grower than the yearly crop of lambs sold for meat. In most of the Down breeds the meat, produced chiefly as fat lambs, is more valuable than the yield of wool.

In a few parts of the world, such as in the Roquefort cheese-producing region in France and the Balkan countries, sheep are triple-purpose creatures because of their yield of milk. Even in their production of wool, sheep vary greatly. Some breeds yield long, coarse wool used chiefly in rug- and carpetmaking, like the sheep bred by the Navaho tribe of American Indians, which yield a coarse, carpet-type fleece. Merino wool can be woven into a fabric almost as sheer and resilient as silk, yet possessing greater strength and warmth. Karakul sheep yield a tightly curled, beautifully patterned and lustrous soft dark fur. It was found that the curl size of Karakul lambskin fur was shifted favourably toward a smaller curl by selection in the breeding flock over a few generations.

Environment, distance from market, and economic competition also influenced sheep types. Some breeds, such as the Rambouillet, have a natural herding instinct. They graze by day and bed down at night in closely gathered flocks, sometimes containing more than 1,000 sheep. Sheep which scatter when grazing because of lack of the herding instinct would soon be lost or fall victim to predatory animals.

Fortunately it was possible, by careful breeding, to make notable progress with the Rambouillet as to staple length of wool, mutton type, and freedom from skin folds. Not only are good mutton type and condition of flesh associated with heavier body weights and fewer skin folds, but staple length of wool and the weight of wool, either as clean or grease wool, are positively associated. Freedom from wool blindness is somewhat less closely associated. Progress was far greater from the selection of sires than from the selection of dams.

The semiarid regions of Australia, where an area three-fifths as large as continental United States averages only 15 in. of rainfall a year and offers spare grazing of a weedy, shrubby character, are unsuitable for producing choice fat lambs, but the Merino sheep with its excellent fleece of fine wool thrives there. The long distance of Australia from most of the world's markets is not a seri-

ous factor for a product as imperishable and light in weight as wool. A notable post-World War II development was the increase in "other" breeds, mainly Corriedales and Polwarths. The Merino was found to be uncommonly effective in grading up the common sheep flocks of India and the Middle East.

Shifts in the relative profitability of mutton and wool have been a cause of considerable crossbreeding in sheep production. The Corriedale breed, which originated in New Zealand, is about equally valuable for lambs and wool under range conditions. The same is true of the Columbia. The Corriedale and Columbia possess the herding instinct; their ewes have the mothering qualities so necessary in range sheep and they produce large lamb crops. The Corriedale is adaptable to areas as diverse as Kenya and Tierra del Fuego and gives a high lambing ratio. Flocks were established in most sheep regions, particularly those of the southern hemisphere. In western United States, Corriedale rams were used especially on Rambouillet ewes to give an improved quarter-bred.

Scientific crossing has given good results. Crossbred Hampshire, Shropshire, and Southdowns gave a much better survival ratio to weaning time, plus more rapid weight gains. Crossing of Columbia with Southdown gives wool production of very good staple length, quality, and quantity, as well as producing excellent feeders with a satisfactory market finish at desirable weights. Southdown and Shropshire lambs excel in edible meat production, giving the highest proportion of preferred cuts, including legs, loins, and ribs.

In the United States several state and regional experiment stations, particularly the sheep experiment station at Dubois, Ida., and the southwestern range and sheep breeding laboratory, Fort Wingate, N.M., compare different systems of breeding and develop more effective methods of selection. Various traits of lamb and wool production are analyzed for heritability and economic importance. Comparisons are made between inbred lines formed by selection within lines and by recurrent selection of sires from line-cross and top-cross progeny tests. Non-inbred selected groups are developed in each breed for comparison with inbred lines and their crosses. A genetically stabilized group is also established with selection at random to serve as a control for the selected groups.

(J. K. R.; M. A. D.)

CARE AND MANAGEMENT

This differs considerably from area to area, and more particularly between the small flock of 10 to 100 operated as an incidental part of a general farming operation and the large ranch or station band of one to several thousand head. The latter may involve moving with the season from valley to mountain to valley again (transhumance) over long trails distant from the home base.

Such far-flung operations may require spending the major part of the year on public land, returning to the home base only for wintering and the spring lambing season.

Regardless of the size or nature of the operation, skilled care and attention is required at lambing time, not only to assist with difficult deliveries but especially to make certain that the lamb does not become chilled after birth and that the ewe recognizes the lamb and allows it to nurse. Heat lamps are used to some extent to warm and dry the newborn. Protection and even rescue and perhaps supplementary feeding of the flock may be required during the worst winter months in some areas, particularly if there is deep snow.

It is seldom profitable to feed grain to breeding sheep or suckling lambs as long as they have an abundance of succulent grazing forage. Though they do best on pastures and ranges which provide

SUFFOLK RAM

CORRIEDALE RAM

CORRIEDALE EWE

BY COURTESY OF THE U.S. DEPARTMENT OF AGRICULTURE

choice grass or legume forage which is short and fine, they will consume considerable quantities of high, coarse, brushy material and weeds.

Hay and other roughage can be used, particularly in winter or drought periods. Grain may be used in small amounts for flushing at breeding time and, of course, for fattening. Fattening on grain and concentrates is carried on mostly between the ranch and the consuming market and in general is a more delicate operation than cattle fattening. In some areas lambs may be sent to market "milk fat" from the ewe at 3 to 5 months of age; the greater part of the annual lamb crop moves to market at the close of the range season at 6 to 9 months of age.

Except on alkali ranges, breeding sheep must be provided with about one-half ounce of salt a day and fattening lambs about half as much. Calcium supplements of about one-fourth ounce a day may be needed if legume forage or hay is not included. Phosphorus, if deficient in the range plants, may be supplemented by adding two parts of bone meal to one part of salt. In areas where newborn lambs are afflicted with goitre, iodized salt in moderate amounts may be fed to the pregnant ewes. Vitamin A appears to be the only one likely to be deficient and that when food is limited to cereal straws, low-quality hay, or cottonseed hulls.

Sheep need as much as $1\frac{1}{2}$ gal. of water a day, though dew on grass or snow, if available, may suffice for much of the requirement. They should not have to travel more than three to four miles between grazing and water in cool weather, or about two miles in warm weather; animals with young should be even closer. Thus the number of animals which may be supported in semiarid areas is rather strictly limited by the availability and spacing of water holes.

Shade during hot weather is desirable as is protection from predatory animals—dogs, wolves, eagles, etc. Sheep should be shorn only when the fleece is dry and settled weather is in prospect, for wet snowstorms or severe cold may cause heavy losses from exposure after shearing unless protection is available. Except in areas of bitter winter, only the simplest shelter or none at all is required.

Approximately one mature ram is kept for each 35 ewes, unless artificial insemination is employed. Range ewes are seldom kept beyond the sixth year though they may be moved to areas with softer food and used as breeding stock for one or more additional years.

There is considerable variation in lamb crop, loss of animals and, of course, in income, from year to year. Under range conditions the annual lamb crop may average less than 75% of the number of breeding ewes maintained; in smaller farm flock, with an effort to save twins and triplets, the lamb crop may exceed the number of breeding ewes. The wool clip under favourable management will average 10 lb. per head for some breeds.

Diseases.—*Bacterial and Viral Infections.*—Prior to the 20th century, sheep owners commonly accepted heavy losses in their flocks as inevitable. After the early 1900s, however, marked progress was made by the veterinary profession in the prevention and control of many of the bacterial and viral infections that were once ovine scourges.

Bacteria of the genus *Clostridium* probably cause greater death losses than any other single class of microorganisms. These spore-bearing organisms are capable, generally, of producing powerful, lethal toxins. Some of the diseases they produce in sheep, and the organisms which cause them, are as follows: enterotoxemia, struck and pulpy kidney disease, caused by *C. perfringens;* braxy or bradsot, *C. septicum;* blackleg, *C. chauvoei;* black disease or infectious necrotic hepatitis, *C. novyi;* tetanus, *C. tetani.* The symptoms effected by the different *Clostridium* infections are frequently very similar; accurate diagnosis can only be made on bacteriological isolation and identification of the causative agent.

Struck, braxy, and black disease are particularly acute and lethal diseases. As in infection by anthrax (*q.v.*), affected sheep may die in a few hours after they first show symptoms, or they may be found dead without symptoms ever having been observed. These diseases are peculiar in that they commonly affect the most vigorous and thrifty sheep in the flock. Fortunately, through proper management and vaccination, losses from these diseases may be largely controlled, if not eliminated.

Struck or lamb dysentery affects the young, as the latter name implies. Unsanitary conditions and close confinement contribute to the danger from this disease, which attacks in from a few hours to a week after birth. The mortality may be high if precautionary measures are not used. In the second half of the 20th century the anthrax problem was not as serious in the western hemisphere as in the old world, where repeated epizootics of anthrax over the decades and centuries resulted in heavy contamination, particularly in Asia, southern Europe, and Africa.

The spore form of the anthrax bacterium (*Bacillus anthracis*) is very resistant to chemical and environmental influences and can survive for years in contaminated soil and in animal products, including wool. Feedstuffs and fertilizers, moreover, may be contaminated. The main source of infection in agricultural workers is from contact with contaminated carcasses, wool, hair, hides, and insufficiently cooked meat.

Many different preparations of anthrax spore vaccines are useful for the prevention of the disease, particularly spore suspensions in glycerin-saline solution for intradermic use and spore suspensions in saponin solution for subcutaneous use. The avirulent, noncapsulated strain of *B. anthracis* used in the spore vaccine developed at the Onderstepoort Veterinary Research Laboratory, Pretoria, S.Af., was used with considerable success in many countries.

Blackleg, tetanus, and malignant edema result from infections of wounds. The freshly ruptured navel, shearing cuts, and the wounds resulting from castration, docking, and earmarking are the usual avenues for entrance. To prevent these diseases, great care should be taken in operations, using clean instruments and techniques. Lambing should be done in cleaned and disinfected buildings or, when weather permits, outside on uninfected land. Infections with pus-forming bacteria also enter through wounds, resulting in arthritis and abscesses in the internal organs, including the brain and spinal cord. An effective means of prevention is to dip the stump of the navel cord in tincture of iodine or other effective antiseptic as soon as possible after birth.

Contagious pustular dermatitis or sore mouth is an especially widespread virus disease of sheep and goats. The disease occurs in England and other parts of Europe, North and South America, and Australia. Aside from the loss of body weight that results, the disease is usually not serious. The animals usually recover, but secondary infections caused by bacteria, especially *Sphaerophorus necrophorus,* may cause death. An effective vaccine was developed as a preventive.

Bluetongue, a little-known virus, has infected thousands of sheep in the southwestern United States and is known in other countries. Studies of scrapie, a disease involving the central nervous system, indicate that its transmission may be by a viral agent linked to certain genetic factors.

Foot rot or foul foot, due to infection with *S. necrophorus*, is more or less prevalent in most sheep-raising countries of the world. Because of extreme pain in the feet, some animals on sparse pastures may starve to death through inability to travel and procure feed. Cure is tedious and painstaking. The infection may be largely avoided by preventing healthy sheep from having contact with infected sheep or soil.

Sheep rarely develop tuberculosis. The few cases observed were mostly of the avian type, contracted from tuberculous fowls. A common disease of sheep the world over is pseudotuberculosis or caseous lymphadenitis. It is a chronic, bacterial disease of the lymph nodes, caused by *Corynebacterium ovis* (*Preisz-Nocard bacillus*). It seldom causes death, except in aged animals, but it requires considerable attention from the standpoint of meat inspection.

In some flocks mastitis (inflammation of the udder, blue bag) is a serious problem. Various bacteria are implicated as causative agents. Sanitation and biological products may be applied as preventives.

Louping ill, an encephalitis caused by a virus, was reported only

from Scotland and other parts of the British Isles. The disease is transmitted by the tick *Ixodes ricinus*. An effective vaccine was developed as a preventive.

Pregnant ewes, especially those carrying twins or triplets, may develop pregnancy toxemia or pregnancy disease if they are underfed, closely confined, or subjected to sudden changes in feed or environment. Treatment is generally ineffectual for this highly fatal metabolic disease. Prevention consists in keeping ewes in a thrifty gaining condition during pregnancy, especially during the last two months.

Other diseases that affect sheep, but are generally less widespread or less serious than those mentioned, include sheep pox, Johne's disease, hemorrhagic septicemia, paratyphoid, rabies, foot-and-mouth disease (*q.v.*), Q fever, and various forms of malnutrition. (M. S. Sn.; J. K. R.)

Parasites.—Sheep probably suffer more from parasitism than any other class of livestock, the damage being greatest among lambs and young animals. The losses from the effects of protozoa, worms, and arthropods are so extensive at times as to make sheep raising an unprofitable undertaking. Fortunately, control measures for most parasites are available and, if followed, the loss can be substantially reduced.

The most injurious of the protozoan parasites are coccidia, of which there are several species. Coccidia are minute animals that develop in and destroy the cells lining the intestinal tract, causing bloody diarrhea and frequently death. Coccidiosis (*q.v.*) is particularly prevalent where lambs are concentrated in feed lots for fattening and finishing for market. It can be controlled to a large extent by sanitation and frequent cleaning of the feed troughs to prevent accumulation in them of manure containing the oöcyst or infective stage of the organisms, which may be swallowed with the feed.

The worm parasites include flukes, tapeworms, and roundworms. The common liver fluke (*Fasciola hepatica*) occurs in most parts of the world and is one of the deadliest parasites of sheep. The flat, leaflike parasite lives in the liver, causing a condition known as liver rot. The symptoms of fluke infestation are principally unthriftiness, anemia, and abdominal dropsy, and differ little from those caused by other worm parasites. An acute, frequently fatal bacterial disease known as black disease is often associated with liver fluke infestation. The life cycle of the fluke is complicated, requiring water snails (*Lymnaea* and related genera) as intermediate hosts. The larval stages develop in the snails and the infective stage, or cercaria, that escapes becomes encysted on aquatic vegetation and is swallowed by sheep while grazing.

Control of liver flukes depends upon destruction of the snails, either by drainage to destroy their breeding places or by the use of chemical poisons, such as copper sulfate, broadcast over the snail-infested areas. Medicinal treatment with small individual doses of carbon tetrachloride or hexachlorethane will destroy the adult flukes in the bile ducts. Young flukes in the liver tissue are not affected by the treatment.

Several species of adult tapeworms parasitize the digestive tract of sheep, but as a general rule they cause little injury. The fringed tapeworm (*Thysanosoma actinioides*) frequently occurs in the bile ducts, rendering the liver unfit for human consumption. So far as known, the larval stage of sheep tapeworms develops in grass mites The larval stages of several dog tapeworms (*Echinococcus granulosus*, *Taenia hydatigena*, and *T. ovis*) occur in sheep; they render the carcass or the organs affected unfit for food. As a preventive measure, all dogs on farms where sheep are kept should be examined periodically for tapeworms by a veterinarian, and the infested animal should be treated for their removal.

The important roundworms of sheep are the stomach worm (*Haemonchus contortus*), nodular worm (*Oesophagostomum columbianum*), and several species of small threadlike worms belonging to the genera *Cooperia*, *Ostertagia*, and *Trichostrongylus*. Infestations are acquired by the animals while grazing. The common symptoms are unthriftiness, anemia, and diarrhea. Death loss from stomach worms and the small roundworms is sometimes very extensive. In addition to the usual bad effects of parasitism caused by roundworms, the nodular worm ruins the small intestines for use as sausage casings, surgical suture material, and for other purposes. In areas where freezing weather prevails for long periods, the infective larvae of roundworm parasites on pastures are destroyed. Treatment of the breeding flock with appropriate doses of thiabenzole or of phenothiazine is used to control infestations.

The arthropod parasites include the sheep tick or ked, nose grub, screwworm, and several kinds of lice and scab mites. The sheep ked is a wingless fly which sucks blood and causes skin irritation; it also stains the wool and reduces its market value. Keds may be controlled by immersing infested sheep in dips containing rotenone or other insecticidal substances and also in an aqueous suspension of 0.03% lindane. Nose grubs, which are larvae of the sheep bot fly *Oestrus ovis*, live in the head sinuses. They may be destroyed by spraying into the nostrils, under pressure, a solution of saponified cresol. The larvae of the screwworm fly (*Callitroga hominivorax*) infest wounds and cause extensive damage. Screwworm infestations are best treated by the application of a smear having diphenylamine as its basic ingredient. Lice suck blood and irritate the skin; they may be controlled by the use of insecticidal dips or applications containing coal tar creosote, arsenic, or nicotine. Scab mites cause skin irritation, falling out of the wool, unthriftiness, and even death; control or eradication is accomplished by dipping in lime sulfur and nicotine dips.

A dip prepared from diazone or from benzene hexachloride (BHC) is highly effective against scale mites and requires only one dipping instead of the usual two needed when the older dips are used. The dipping vat is filled with enough clean, unheated water to cover the sheep and the required amount of diazone or BHC powder added and thoroughly stirred. The head of each sheep is submerged at least twice for an instant so that the wool about the head and face is thoroughly wet.

(E. W. Pe.; J. K. R.; M. A. D.)

WORLD SHEEP INDUSTRY

Major Producing Areas.—Distribution of sheep is, of course, limited by grazing lands and somewhat by climatic conditions. Some cold areas, even if unfavourably wet, are usable, and warm areas, if dry, are used, but sheep are not numerous in the warmer areas of the tropics.

However, northern Australia above the Tropic of Capricorn contained in the 1960s fully 5% of the more than 160,000,000 sheep population of Australia. These were about 75% Merinos and grazed successfully, except for some problems of infertility which are not uncommon in hot arid areas with approximately equal hours of daylight and darkness.

The distribution pattern of sheep differs from other livestock in the emphasis on the southern hemisphere. Entirely a development that occurred after 1850, it appears to be related, first, to the storability and transportability of wool, well adapted to frontier conditions of subhumid climates.

In such subhumid areas the Merino sheep with its fine apparel wool developed under large-scale ranching conditions. Later the development of refrigerated ocean shipping enabled some of the thinly settled areas to increase the production of lamb for the European market.

World sheep numbers in the 1960s stood near 1,000,000,000 head, about one-third more than pre-World War II. Increases in the U.S.S.R. were particularly rapid. Other leading sheep-producing countries were: India, China, Turkey, and Iran in Asia; Australia and New Zealand in Oceania; United Kingdom, Spain, and Italy in Europe; Argentina, Uruguay, and Brazil in South America; South Africa and Morocco in Africa; United States in North America. There were increases in all continents except North America, where sheep numbers decreased by 35%. The decline in the United States is difficult to understand at first glance. One might think that emphasis on soil conservation, grassland farming, new developments in better-adapted and more productive grasses, and the adoption of new ways of curing hay and making and using grass silage should have led to increased sheep production.

The explanation appears to be more in the realm of comparative

economics and cultural trends. Cattle seemingly made more profitable the use of some grazing areas which previously had been devoted to sheep, paying a better return on capital invested. Moreover, labour of the types needed for successful sheep ranching, particularly the excellent Basques, became increasingly difficult to obtain. (M. S. Sn.; J. K. R.)

Products.—For wool and meat production, *see* Wool; Lamb and Mutton. The pelt is also a major by-product of sheep slaughter. The pelts, with the wool removed, known as slats, are tanned for leather which is used for upholstery, bookbinding, gloves, clothing, and shoe uppers. With the wool, the pelts are a basic material for the manufacture of durable and warm outer clothing.

Not only the carcass as such but the liver, heart, kidney, and some other parts are used for human food. Some of the internal glands have pharmaceutical uses. The small intestines are valuable sausage casings and are significant in international trade. They also are used to make surgical and musical catgut. Wool grease or lanolin has important uses in lubricants, ointments, and cosmetics. Sheep tallow has both edible and inedible uses.

Live sheep enter international trade in comparatively small numbers, mostly as select breeding stock.

SHEERNESS, a seaport, naval establishment and urban district on the Isle of Sheppey (*q.v.*), in the Faversham parliamentary division of Kent, Eng., on the right bank of the Medway estuary at its junction with the Thames, 48 mi. E. of London. Pop. (1961) 13,691. The town is divided into three sections—naval; residential and business; and recreational. Blue Town, the oldest, contains the naval dockyard built on a site surveyed by Samuel Pepys, secretary to the Navy, in 1665. The fort at Garrison point was built after the taking of Sheppey by the Dutch in 1667. In 1797 Sheerness was involved in the Nore mutiny by the landing in force of the mutineers and it was there that Lord Nelson's body was brought ashore from his flagship, the "Victory." Mile Town, built after Blue Town, comprises shopping and residential streets; while Marine Town, lying along the sandy eastern shore, forms an additional residential area, with pleasure gardens and an open-air swimming pool.

SHEFFIELD, a city, county and parliamentary borough in the West Riding of Yorkshire, Eng., 158 mi. N.N.W. of London, 38 mi. E.S.E. of Manchester and 52 mi. S.S.W. of York by road. Pop. (1961) 494,344. Area 61.9 sq.mi. It is in the extreme south of the county, at the foot of the Pennines and at the junction of the Don with its tributaries the Sheaf, Porter, Rivelin and Loxley.

At the time of the Domesday survey Sheffield (Escafeld) was a subdivision of the large manor of Hallam. At that time the Meersbrook, the Limb Dyke and the Sheaf, which had divided Mercia from Northumbria, were the boundary between Yorkshire and Derbyshire and continued to be so until 1900. After that, extensions of the city boundary carried Yorkshire several miles into Derbyshire.

Early in the 12th century, the Norman William de Lovetot built a castle at the confluence of the Sheaf and the Don, and a parish church. These two focal buildings were in, or near to, the submanor of Sheffield, and this was no doubt why the name of Sheffield soon superseded that of Hallam for the town and manor; though Hallamshire (Sheffield, Ecclesfield and Bradfield) continued to be an area of administration cut off from the rest of Yorkshire by the great moors north of Bradfield.

In 1297 Thomas de Furnival, then lord of Hallamshire, granted to his "Free tenants of the town of Sheffield" certain privileges as burgesses. These free tenants continued to be the body most concerned with local government until in the reign of Edward VI certain property which had been left to them in trust was forfeited to the crown under the Act for the Suppression of Colleges and Chantries. On their petition it was restored by Queen Mary in 1554, and as she preferred to separate the ecclesiastical from the civil duties she created by charter a body of 12 capital burgesses who discharged their functions side by side with the free tenants. Both are now charitable trusts—the Church Burgesses and the Town Trustees. Mary, queen of Scots, spent some time at the Manor lodge during the 14 years of her captivity at Sheffield castle.

Industries.—The district is rich in sources for metalworking. From early times the local iron ore had been smelted by charcoal obtained from the abundant woodlands. Smiths, and probably cutlers, were active in the neighbourhood as early as the 14th century. The millstone grit of the district provided excellent grindstones. During the 15th century the streams which converge on Sheffield began to be used for power for grinding and forging. Though the cutlery industry was for many years a rural one, carried on in a succession of water mills which packed the banks of the rivers from their sources on the moors to the boundary of Rotherham, the importance of Sheffield was established as the market town where the wares were finished and sold. This resulted in its emergence as the main provincial cutlery town and a powerful rival to the cutlery trade of London. By 1700 the London cutlers also were defeated; thereafter Sheffield enjoyed a monopoly of the English cutlery trade. The variety and quality of products reached a very high level in the late 18th and early 19th centuries—spring and table knives, razors, scissors, surgical and mathematical instruments, edge tools, saws, agricultural and joiners' tools, files and rasps of every grade and size. The introduction of steam grinding released the industry from its dependence on the rivers but until very recent times there was little change in the organization of an essentially small-firm industry.

The crisis of Sheffield's industrial history was reached about 1740, when Benjamin Huntsman moved from Doncaster to Handsworth (now within Sheffield) to experiment in the production of a steel harder and more even than could be made by the older methods of smelting and forging. The crown of his experiments was crucible steel, the reliable tool steel which marked the beginning of special steelmaking in England. By 1830 Sheffield was recognized as the centre of high-grade steel manufacture. Shortly afterward the opening of the first local railways made possible the movement, and therefore the manufacture, of really large castings. It followed naturally that when in 1856 Henry Bessemer invented his method of making inexpensive steel in large quantities, he should set up a works in Sheffield. During the remainder of the 19th century the heavy industries grew rapidly, aided by the development, by Sir John Brown (*q.v.*) and Charles Cammell of the manufacture of armour plate for ships, and the discovery by Sir Robert Hadfield (*q.v.*) of a workable manganese steel. Development in alloy steels, including the perfection by Harry Brearley of noncorrosive ("stainless") steel, in 1912, went on apace. The area between Sheffield and Rotherham was quickly filled with the great works which clang and glow so impressively through the night in the Don valley.

About the same time that Huntsman was experimenting Thomas Boulsover, a cutler, discovered the process of plating copper with silver by fusion which resulted in the beautiful ware

known as old Sheffield plate. (See SHEFFIELD PLATE.) Factories for making it were established rapidly and played a large part in bringing to the town wealth which had eluded the older small-scale cutlery manufacturers. The discovery of the method of electroplating killed the more expensive plate trade almost overnight in 1850, and the surviving specimens have become museum pieces eagerly sought by collectors; but the silver and electroplating trades continue, and the city still has one of the few provincial assay offices (established 1773).

The cutlers organized their industry on craft guild lines very early; the first trade-mark known was granted in 1554. In 1624 they were incorporated as the Company of Cutlers in Hallamshire, with jurisdiction for six miles round Hallamshire as well. As a guild, the company relinquished most of its powers in 1812, but has since revived as a powerful influence in upholding the quality of Sheffield wares. By acts of 1883–88, the company has the right of registering trade-marks for all goods composed in whole or in part of any metal, wrought or unwrought, in its ancient area of jurisdiction, and its membership now includes the manufacturers of steel as well as cutlers.

Although the cutlery, steel and auxiliary trades still occupy the greater part of Sheffield's wage earners, there are important minor industries. Haft, handle and case making naturally accompany the cutlery trades. Sheffield has the largest type foundry in England and there are snuff factories, food factories, confectionary works, fruit and vegetable canning, iron and brass founding, paper manufacture, bookbinding and the making of optical instruments, bicycles, brushes, railway fittings, chemicals, paints and varnish.

Communications.—Sheffield lies on no great lowland route or natural highway. To the northwest and south the valleys lead to Pennine dales and lofty moorlands. For many centuries the only ways were along steep and narrow tracks, except beside the Don from Rotherham.

In 1726 improvements were made in the navigation of the Don from Doncaster west to Tinsley, to help the trade of Sheffield; in 1814 a canal from the heart of Sheffield to Tinsley completed the outlet by water. Ten turnpike roads made between 1756 and 1819 brought the town out of its isolation, but the gradients daunted the early railway engineers, and the first line, opened in 1835, only connected Sheffield with Rotherham, on the original Midland line.

The present main line through Chesterfield was not built until 1876, after the tunnelling of the Sheaf-Rother watershed. Long tunnels connect Sheffield by rail with the west and even in the 1950s relatively little of the trunk traffic of England passed through the city.

Later History.—During the period generally known as the Industrial Revolution the population expanded so rapidly that the ancient bodies of local government could not cope with the new problems of urban management. The first interest of the day was in parliamentary reform and in 1832 Sheffield was allotted two members in the reformed parliament. The Municipal Corporations act of 1835, allowing named towns to apply for a charter of incorporation as boroughs of the modern type, was adopted in 1843. In 1893 the borough was created a county borough and city and in 1897 its chief magistrate received the title of lord mayor. In 1911 the census returns showed that Sheffield had taken a place above Leeds as the largest city in Yorkshire. In this period the built-up area spread rapidly along the valleys; during the 20th century pleasant new suburbs were extended over the hillsides.

In 1914 the diocese of Sheffield was created from the see of York, the old parish church becoming the cathedral church of St. Peter and St. Paul. Only the tower and chancel of the 15th-century building (which replaced two earlier ones) remain, but the present building has some fine alabaster monuments and some interesting modern stained glass.

In 1897 the university college was created by the amalgamation of the medical school (founded in 1828), the technical school (1886) and Firth college (1879), a university extension venture for which Mark Firth, a steel manufacturer, had provided the building. In 1905 the college received its charter as the University of Sheffield. Although it provides ample opportunities for a broad cultural education, the university especially developed branches of study and research in glass and fuel technology, metallurgy, mining and engineering. Sheffield was one of the first towns to provide secondary education; at mid-20th century there were eight grammar schools, including King Edward VII school, formed in 1905 by the union of the old Royal Grammar school and two private schools, administered by the municipality. There were also colleges of arts and crafts, and commerce and technology.

BARNABY'S PICTURE LIBRARY

THE TOWN HALL, SHEFFIELD, DESIGNED BY C. W. MOUNTFORD, 1897. THE TOWER IS CROWNED WITH A BRONZE STATUE OF VULCAN

The town hall, opened in 1897, is a good example of Victorian Gothic housing the municipal offices. Twentieth-century buildings include the city hall (1932) for concerts and meetings; the city museum (1937) with excellent collections of cutlery, plate and Derbyshire antiquities, and the central library and Graves art gallery (1934). The library is a fine one, well known for material on ferrous metallurgy and for collections of local archives. In Meersbrook park was the Ruskin museum (closed 1952) containing John Ruskin's collection of works of beauty lent to Sheffield from St. George's guild by his desire.

Sheffield's growth and appearance have been adversely affected by the lack of large commercial undertakings in earlier periods, by the necessarily dirty nature of its major industries and by two heavy air raids sustained in Dec. 1940. Nevertheless, finely sited on a hill-and-valley system of great beauty, Sheffield is a pleasant and in some ways a beautiful city. There are open spaces and tree-lined streets less than a mile from the city centre, and the purple moors of the Pennines and the deep wooded dales of Derbyshire sweep up to the very edge of the residential area.

See A. Gatty, *Sheffield: Past and Present* (1873); *Handbook and guide to Sheffield*, pub. for Brit. Ass. (1910); M. Walton, *Sheffield; Its Story and Its Achievements*, 3rd ed. (1952). (My. W.)

SHEFFIELD PLATE, articles produced from copper to which a coating of silver has been fused. The process was discovered about 1742 in Sheffield, Eng., by Thomas Boulsover (Bolsover), a cutler, and was soon used to make food-serving dishes and the like. Design and workmanship were in time brought to a very high level, and these early pieces were sometimes impressed with hallmarks resembling those used on silver—a practice that was prohibited by an injunction obtained in 1773 by the London silversmiths. By 1774, however, the Sheffield plate makers were again authorized to use marks that bore the name of the maker and a distinctive device not used for silver. The industry was located almost entirely in Sheffield, where there were a number of manufacturers, and to a lesser extent in Birmingham, where the great name was that of Matthew Boulton (*q.v.*). By about 1860 the fusion process had been superseded by electroplating (*q.v.*) and the industry was defunct.

About 30 years after its disappearance as a commercial commodity, the acquisition of "old Sheffield plate" became a cult among collectors. Since the demand soon exceeded the supply, a number of manufacturers began to make pieces reproducing the old designs by electroplating on copper. The sale of such

pieces as "Sheffield plate" provoked the Sheffield Cutlers' Company to take action, and in 1911 it was established in court that the term "Sheffield plate" could only be applied to articles made by the process of plating by fusion. An intermediate category of goods was left, however, of genuine "Sheffield plate" which had been worn through to the copper by hard usage and later electroplated.

The cult of "old Sheffield plate" gradually declined and specialist collectors disappeared, although the more ornamental pieces such as candelabra and tea urns, which can be lacquered and used as decorative adjuncts to antique furniture, continued to be prized by connoisseurs.

BY COURTESY OF SHEFFIELD CITY MUSEUM

SAUCEPAN, BY JOSEPH HANCOCK, MADE ABOUT 1755, SHEFFIELD, ENG.

BIBLIOGRAPHY.—F. Bradbury, *A History of Old Sheffield Plate* (1912) remains the standard authority; S. B. Wylear, *The Book of Sheffield Plate* (1949) includes reproductions of early electroplaters' marks, which serve as a check during the period when firms were changing from fused to electroplating; E. Wenham, *Old Sheffield Plate* (1955) gives a concise account of the subject.

SHEIKH (SHAIKH or SHAYKH), an Arabic title of respect dating from pre-Islamic antiquity, strictly means a venerable man, of more than 50 years of age. It is specially borne by heads of religious orders, heads of colleges (*e.g.*, Al Azhar in Cairo), chiefs of tribes, and headmen of villages and of separate quarters of towns. It is also applied to learned men, especially members of the class of *'ulama'* (*q.v.*), and has been applied to anyone who had memorized the whole Koran, however young he might be.

Combined with other terms the word is used in various titles: *shaikh al-balad*, mayor of a town; *shaikh al-jabal* ("the mountain chief"), a popular term for the head of the Assassins mistranslated by the crusaders as "the Old Man of the Mountain" (*see* ASSASSIN). By far the most important of these is the title *shaikh al-Islam*, which by the 11th century A.D. was being given to eminent *'ulama'* and mystics and by the 15th century could be claimed by any outstanding mufti (*q.v.*). In the Ottoman Empire this title was restricted by Suleiman I (1520–66) to the mufti of Istanbul, who was equal in rank to the grand vizier and was head of the religious institutions which controlled law, justice, religion, and education. Because of his right to issue legally binding *fatwas* (opinions) this official came to wield great power. In 1924, under the Turkish Republic, the last vestiges of the institution were abolished. (W. M. WT.)

SHEIKH OTHMAN, a town of Aden state, part of the British colony of Aden, in the Federation of South Arabia, lies on the sandy mainland part of Aden, about 6 mi. N of the port. Pop. (1960 est.) 35,000. Purchased from the sultan of Lahej in 1882 as a settlement for the surplus population of the Aden Peninsula, it proved too unhealthy until sanitary measures completely changed the outlook. Governed municipally by the Settlement Committee when Aden formed part of British India, in 1945 Sheikh Othman (including the villages of Hiswah, Al Burayqah (Bureika), Bi'r Fuqum, and Little Aden) was given its own township authority. In 1955 Little Aden and the fishing villages of Al Qaissa (Al-Khaisa) and Bi'r Fuqum were granted separate status as the Little Aden Township Authority. (W. H. IS.)

SHEKINAH, a Hebrew noun (derived from the verb *shakan*, "dwell") meaning "dwelling" or "presence" with specific reference to the presence of God. It first appears in the Aramaic form *shekinta* in the paraphrastic Aramaic translations of the Old Testament known as Targums (*see* TARGUM), and is used frequently in Talmud and Midrash and other postbiblical Jewish writings. In the Targums it is used, like *memra* ("word") and *yeqara* ("glory"), as a substitute for "God" in passages where the anthropomorphism of the original Hebrew seemed likely to mislead. Thus, in Ex. 25:8, "that I may dwell in their midst" becomes in the Targum of Onkelos "and I will cause my Shekinah to rest among them." By this usage belief in the omnipresence and transcendence of God was safeguarded; and in many passages Shekinah is simply a reverential substitute for the divine name.

In rabbinic literature the Shekinah is associated with several other religious and theological terms. There is appropriateness in the thought that the Shekinah descended on the tabernacle (Hebrew *mishkan*, from the same root as Shekinah) and on Solomon's Temple, though it is said that it was one of five things which were lacking from the Second Temple (the other four being the ark, holy fire, spirit of prophecy, Urim and Thummim; *see* TEMPLE, JEWISH). The glory of God which filled the tabernacle (Ex. 40:34) was thought of as a bright radiance; and the Shekinah is sometimes similarly conceived. This idea appears in John 1:14, where the Greek verb "dwelt" or "tabernacled" (*eskenosen*) recalls the form as well as the sense of the Hebrew verb *shakan*. There is also an affinity between the Shekinah and the Holy Spirit, though the two are not identical. Both are associated with prophecy; both may be lost because of sin; and both are connected with the study of the Torah. Two later developments of the idea are that the Shekinah was a created entity, distinct from God (Maimonides), and that Shekinah was a female element in God: the bride and daughter of God (Cabala).

SHELLEY, MARY WOLLSTONECRAFT (1797–1851), English writer, who has a place in literary history as the author of *Frankenstein*, and as the daughter of William Godwin and Mary Wollstonecraft Godwin (*qq.v.*) and the second wife of Percy Bysshe Shelley, was born in London on Aug. 30, 1797.

MARY WOLLSTONECRAFT SHELLEY, PORTRAIT BY R. ROTHWELL, 1841

Mary came as near as any woman could to meeting Shelley's requirements for the partner of his life: "one who can feel poetry and understand philosophy." After his death in 1822 she published his *Posthumous Poems* (1824), edited his *Poetical Works* (1839), with long and invaluable notes, and his prose works (*Essays, Letters from Abroad*, etc., 1840). Her *Journal* is the backbone of Shelley biography and her letters are an indispensable adjunct.

Frankenstein, or the Modern Prometheus (1818) is perhaps the most widely known pseudoscientific novel. Its style is immature, but the basic idea is fascinating: the power of the scientist to form and give life to a human being and the dreadful consequences which this act produces. The treatment of psychological and social problems is extraordinary, the more so in that the book was completed before Mary's 20th birthday. Her second, historical, novel, *Valperga: or, the Life and Adventures of Castruccio, Prince of Lucca* (1823), is in literary style her best work; it was produced under Shelley's direct stimulus. But in general esteem *The Last Man* (1826) ranks as her best novel. In this and later novels—*The Fortunes of Perkin Warbeck* (1830) excepted—she made use of her rich early life by portraying Shelley, Byron, Emilia Viviani (the inspiration of Shelley's *Epipsychidion*), E. J. Trelawny (*q.v.*), and real episodes from her experience. *Lodore* (1835) and *Falkner* (1837) are inferior to the earlier novels. To Dionysius Lardner's *Cabinet Cyclopaedia* (1829–46) she contributed *Lives of the Most Eminent Literary and Scientific Men of Italy, Spain, and Portugal*

(1835–37) and *France* (1838–39). Of more permanent value are her travel books: *History of a Six Weeks' Tour* (1817), which recounted the continental tour following her elopement with Shelley in July 1814 and their summer near Geneva in 1816; and her eminently readable *Rambles in Germany and Italy* (1844).

After Shelley's death her life was devoted to educating her only surviving child, Percy Florence, and to assisting her aged father (d. 1836). Shelley's father, Sir Timothy, made only a small allowance for Percy's education, and when, in 1844, Mary achieved monetary freedom following Sir Timothy's death at the age of 90, she was by that time too ill to derive much pleasure from her relative affluence. She died in London on Feb. 1, 1851, and was buried at Bournemouth.

SHELLEY, PERCY BYSSHE (1792–1822), English Romantic poet, was born on Aug. 4, 1792, at Field Place, near Horsham, Sussex. He was the son and heir of Timothy Shelley, Conservative Member of Parliament for Shoreham, and the grandson of Sir Bysshe Shelley, bart. Even as a child he was remarkable for the subtle feeling and originality of ideas which, combined with his later mastery of language, were to give him his place in literature. His short life, dedicated to the promotion of peace and love between individuals and among humanity at large, was, paradoxically, to involve both himself and others in much suffering; this was because his powers and his ideals were often in advance of his experience. Yet out of suffering came a strength which passed into his poetry.

Early Years.—Shelley's childhood was coloured by family affections, a comfortable home, the Sussex countryside, and a world of imagination derived from books, among them the fashionable Gothic or "horror" novels. By 1808, as is shown by early letters, his cousin, Harriet Grove, had become a centre for his affections. From a private school—Syon House Academy at Brentford, Middlesex, where he acquired the rudiments of science—in 1804 he went on to Eton. The brutalities, misery, and sense of isolation he endured there must have affected him. But among the more beneficial results of his schooldays were the fluency he derived from an early training in Latin composition and that robustness of intellect which the classical tradition stimulates in those whose ability is equal to its demands. Before he left school, he published *Zastrozzi: a Romance* (1810), an early attempt at a Gothic romance in the style of Mrs. Radcliffe (*q.v.*). *Original Poetry by Victor and Cazire*, written with his favourite sister, Elizabeth, and published in the same year, revealed a fluency of versifying in metres then fashionable.

At Eton an important direction had been given to Shelley's mind by his elderly friend, Dr. James Lind (1736–1817), a fellow of the Royal Society living at Windsor, who introduced him to Plato and notably to the *Symposium*. In October 1810 he entered University College, Oxford. Though his Greek does not seem, at this stage, to have been as good as his Latin, he read other Platonic dialogues in translation and was eloquently enthusiastic. With this enthusiasm went an eager interest in chemistry, physics, and astronomy. For Shelley, however, as for Lucretius—one of his favourite authors—the "sciences" were a background to the theme of "Man in the Universe," on which he enjoyed discoursing with his fellow student, Thomas Jefferson Hogg (*q.v.*). In November 1810 appeared, supposedly edited by "John Fitz-Victor," *Posthumous Fragments of Margaret Nicholson*, a mock-revolutionary glorification of the mad washerwoman who had tried to stab George III.

At heart, however, Shelley was always repelled by the violence attending revolutionary action. And so, when he was drawn to William Godwin (*q.v.*) and the 18th-century French philosophers, it was not as a revolutionary but as a reformer. For some years he was to be primarily a writer of inquiring prose on politics and theology. But in England at that period, with its panic fear of revolutionary infection from France, even questioning could be dangerous. In disgust at churchmen who professed Christian charity but regarded those reformers who sought to apply its principles to the alleviation of human misery as heretics, Shelley came to question religion itself, and in March 1811 he circulated to the bishops and heads of colleges a pamphlet entitled *The Necessity of Atheism.* Though it was an inquiry into, rather than a denial of, religion, it provided the Oxford authorities with a reason for expelling him, with Hogg, his friend and supporter.

SHELLEY, PORTRAIT BY AMELIA CURRAN, 1819

Harriet Westbrook.—Shelley's father demanded an immediate recantation of the pamphlet and a complete break with Hogg. Refusing both, Shelley, banished from home, settled in London. The views that had already cost him his life at Oxford and at Field Place next lost him the affection of his cousin Harriet. Some clue to the emotional vacuum troubling this part of his adolescence may be found in the epigraph (in Latin) attached to some verses written before he left Oxford, which may be translated: "I was not yet in love and was in love with loving; I was looking for something to love, loving to love." This epigraph was to be used again for *Alastor; or the Spirit of Solitude* (published 1816, preface dated Dec. 14, 1815). It heralds a quest which was to run throughout his life: the quest for a Woman-Symbol, expressive of Intellectual Beauty. Harriet Westbrook, the daughter of a retired hotelkeeper and a school friend of his sisters at Clapham, whom he had met before he left Oxford, became the symbol he needed: in his eyes she was Love and Beauty, demanding to be rescued by Shelley-the-Libertarian from family prejudice, and platonically molded on the lines of the *Symposium.* Five months after leaving Oxford he eloped with her to Edinburgh, where they were married on Aug. 28, 1811; they were remarried in England in March 1814.

His father's anger at the marriage arose more from consideration of Shelley's position and prospects than from any fault in Harriet. Her social inequality has been exaggerated: she was well-bred, charming, and adaptable. All too easily she fell into Shelley's belief that incompatibilities could be smoothed away by study and by the share which a 19-year-old husband and his 16-year-old wife might reasonably expect to have in the Shelleyan agape—that love-power which was to radiate from their household for the reconstitution of mankind. Harriet threw herself enthusiastically into Shelley's schemes, from land reclamation in Wales to the emancipation of Ireland. Forward-looking idealism failed to consider the poverty that might come from this new affront to Shelley's father, combined with Shelley's extravagant generosity to the needy and importunate; nor could present happiness foresee the time when the claims of babies and the learning of Latin would pull the young wife in opposite directions. In their inexperience, Shelley and Harriet failed to recognize the threat to their marriage latent in the presence, almost invariably, of a third person in their household: first Hogg, whose brotherly love for them both soon turned to a more than brotherly love for Harriet; then Miss Hitchener, the Sussex schoolmistress who, from the status of "soul sister" in an immense correspondence, was to become, domestically, the hated "Brown Demon," pensioned off by Shelley; and, finally, the possessive Eliza, Harriet's elder sister.

But the years 1811–12, during which the Shelleys moved energetically about Scotland, England, Wales, and Ireland, were happy. They have their memorial in *Queen Mab*, finished in 1812, and in the delightful dedicatory verses addressed with it to Harriet. This is Shelley's first major poem. Mab, queen of the fairies, takes aloft the soul of the sleeping heroine, Ianthe, and explains to her the significance of what is happening on earth. The voice is the voice of Shelley explaining Godwinism to Harriet, and the exposition marks an important transitional stage in Shelley's devel-

opment as a poet. For a time, in his reaction against Oxford, Shelley had turned from the humanizing influence of Plato to the Godwinian belief in Necessity, a grim power that swayed the forces of destiny, making only a limited allowance for the power of the human will and bringing about, by the process of "mutability," cycles of good and evil in human affairs. As the talk in the poem proceeds, the Lucretian love which "recreates all things" passes into Platonism; and this gradually overlays the Godwinism, till in the end "Necessity" has become identified with the concept of the "World Spirit" (W. B. Yeats's "Spiritus Mundi"). This was to be, throughout Shelley's poetry, a substitute for God. The nine cantos of *Queen Mab* are written in unrhymed Southeyan lines of unequal length that pass into blank verse. The copious notes published with it reveal an immense reading in four languages and a remarkable gift of exposition. Like the poem, they mark the passing of Shelley the potential crank into Shelley the man of genius.

Queen Mab; a Philosophical Poem was privately printed in the summer of 1813. This summer brought new friends and influences. At Bracknell, Berkshire, where the Shelleys took a house in July, Shelley became a member of the intellectual circle of Harriet de Boinville and her daughter Cornelia Turner, with whom he studied Italian. It was at this time too that he began to be intimate with the learned and witty Thomas Love Peacock (*q.v.*). Peacock's conversation gave him some of the stimulus that he might in other circumstances have derived from contemporaries at Oxford. One of its lasting results was his throwing himself into serious study of the Greek writers in their own language. Platonism, from this time onward, became the main fabric of his thought. This by no means excluded other threads. Into the general pattern of his reading and thought went Dante, Calderón, Goethe, and ancient and modern writers too numerous to mention; much scientific literature was included. Shelley was a scholar, humanist, and, always, a man of his time.

Mary Godwin.—Personal poems relating to the accomplished Cornelia Turner, and a reference to his "contemplation of female excellence," may be clues to the comparisons that Shelley was making in 1814. As a Woman-Symbol of Intellectual Beauty, Harriet was no longer adequate. Peacock, the Boinvilles, and others that understood his world of intermingled ideas and feeling could understand this, though they naturally sympathized (as we must) with the affectionate wife who had done no wrong. When, in March 1814, Shelley met Mary Godwin (*see* SHELLEY, MARY WOLLSTONECRAFT), the daughter of Godwin and Mary Wollstonecraft (*see* GODWIN, MARY WOLLSTONECRAFT), she became the new Woman-Symbol, a role for which her parentage alone was a qualification in Shelley's eyes. Godwin's behaviour was typical. When on July 28 Shelley and Mary eloped to the continent (going first to Paris and then to Switzerland), accompanied by Claire Clairmont, Mary's step-sister, to make up the inevitable, recurrent, domestic triangle, Godwin, the philosopher who had preached against marriage, banished Shelley from his friendship. He never ceased, however, to importune him for money. Claire too was to be in many ways a burden to Shelley for the rest of his life.

In September, after financial difficulties in Switzerland, the travelers returned to London and settled at Bishopgate. In January 1815 Shelley's grandfather died, and his father, who succeeded to the baronetcy, decided to allow him £1,000 a year in respect of his expectations. As Harriet and their son, Charles Bysshe (b. 1814), had to be provided for, as well as Mary and the Godwins, this was little, and in a year of anxiety and maladjustment debts loomed large. After leaving England with Mary, Shelley had asked Harriet to join the agape-party as a sister, a Platonic arrangement that seemed to him very reasonable but one that she, not unnaturally, declined. *Alastor*, published, with other poems, in 1816, is a self-projection. It tells of a poet torn by good and evil passions symbolized by pursuing daemons.

In May 1816 Shelley, Mary, and Claire went to Geneva, and, while Claire made the most of the liaison into which she had enticed Byron (*q.v.*), Shelley and Mary enjoyed a Platonic idyll in the scenes consecrated by the lovers in Rousseau's *La Nouvelle Héloïse*. "Mont Blanc" and the "Hymn to Intellectual Beauty" are manifestoes of Shelley's poetic Platonism inspired by those days and scenes; they also inspired Mary's novel *Frankenstein* and the third canto of Byron's *Childe Harold*. Tragedy followed the Shelleys' return to England in the autumn. In November Fanny Imlay, another daughter of Mary Wollstonecraft, committed suicide at Bath, and in December Harriet Shelley was found drowned in the Serpentine, in Hyde Park, London. Harriet's suicide, if suicide it was, is surrounded by mystery. Most biographers have accepted her landlady's evidence that she "appeared to be pregnant," but there is no medical corroboration of this. Other than hearsay there is no evidence either to impugn Harriet's conduct or to suggest, beyond the fact of their separation, any responsibility on Shelley's part. Later disasters always made both Shelley and Mary view her death as the beginning of a chain of encompassing destiny. The events of 1816 ended with Shelley's marriage to Mary (Dec. 30) and the birth to Claire (in January 1817) of Byron's daughter, Allegra.

During 1817 Shelley and Mary, with Claire and Allegra, lived at Marlow, whence they paid many visits to London. It was, in many ways, a happy year. A son, called William, had been born in January 1816; a daughter, Clara, was born in September 1817. Leigh Hunt and his family were constant visitors, and Shelley enjoyed the friendly rivalry of John Keats (*q.v.*), who was then writing *Endymion*, while Shelley was busy with the poem that eventually became *The Revolt of Islam*. There were learned talks and walks with Hogg and Peacock, Claire's singing, and much boating on the Thames—boats, for Shelley, were a symbol, recurrent in his poetry, of the mind's escape from sorrow and evil to a world of goodness, love, and beauty. *The Revolt of Islam* (first printed in 1817 as *Laon and Cythna; or, the Revolution of a Golden City: a Vision of the 19th Century*, and revised under its new title in 1818) is a 12-canto poem in the Spenserian stanza (*q.v.*). It is a transcendental epic of the bloodless revolution and the paradise on earth which can be brought about by the Shelleyan-Platonic agape-love of Laon and Cythna, a hero and heroine who, by a strange adaptation of the brother-brother concept of idealized friendship in Plato's *Symposium*, are also brother and sister. Tediousness is diluted by some fine eloquence, and the dedication to Mary is a delightful example of Shelley's performance in his graceful, lighter vein.

Then came a new disaster. The lord chancellor finally, after a prolonged case, decreed that Shelley was unfit to have custody of Ianthe and Charles, his children by Harriet. Shelley's health was giving way, and he was beginning to fear that Clara and William might also be snatched from him. In March 1818 he and Mary left England forever. Claire and Allegra went with them.

Italy.—The Shelley who fled to Italy with Mary in 1818 was no longer the young reformer who had pursued liberty and justice round England, Wales, and Ireland with Harriet. Though his notebooks are full of statistics and memoranda on contemporary problems, by 1818 the reformer had become merged in the poet, and poetry and allegory, rather than political pamphlets, were to be the vehicle for his social and religious ideas. In Italy he found fulfillment. The sea and sky, the lakes, rivers, and mountains delighted the poet of Nature, while the treasures of antiquity and the Renaissance inspired and exalted the humanist. The Italian years had their sorrows. All three of the children he had brought from England died of disease: Clara in September 1818; William on June 7, 1819; Allegra on April 19, 1822. There were periods of tension with Mary, and there was chronic anxiety about the troubles of Godwin and Claire. Despite these sorrows, and despite constant travel, Shelley maintained a life of unremitting study, composition, and correspondence. Much of the Shelley of 1818–19 went into the great philosophical verse-drama *Prometheus Unbound, a Lyrical Drama in four acts*, published, with other poems, in 1820. Its hero is a libertarian and reformer, persecuted by the ruler of the universe for his attempts to improve the lot of humanity. Not till he has forsworn revenge can he unseat the tyrant. Then, following the union of Prometheus (Mind) with Asia (Love and Beauty), there ensues a reign of peace and happiness on earth. The same gospel of "Spirit, Patience, Gentleness" is the Shelleyan prescription for the workingmen of Manchester

in "The Masque of Anarchy," inspired by the Peterloo Massacre (*q.v.*) of August 1819—though the gentleness of the policy urged is in strong contrast to the ferocity of Shelley's language against purblind refusal to see the need for it. *The Cenci: a Tragedy, in five acts*, written in the summer of 1819, was a triumph of sheer ability, a pastiche written by a man ignorant of the theatre, under the conviction, shared by Keats and others, that a neo-Elizabethan play could be produced by sedulous copying of Elizabethan verse, situations, and effects. Many who, like Mary Shelley, find difficulty in understanding the philosophical content of Shelley's more essential works have followed her in rating this work higher than he did.

The writing of Act I of *Prometheus Unbound* had been followed by the death of Clara Shelley at Este. Acts II and III are full of delight in the Roman spring that preceded the death of William. October 1819 found Shelley and Mary at Florence awaiting the birth of another child. Shelley was full of grief for the revolution he believed to be impending in England and for the loss of his children; he was angry too about the fierce reviews of *The Revolt of Islam*. It seemed that an evil destiny gripped all he had ever loved: were the offspring both of his mind and his body always to perish? But as he walked in the Cascine he watched the windswept leaves, and they became for him a symbol. The symbol grew into the "Ode to the West Wind," Shelley's prayer that his ideas for mankind may be driven over the universe, quickening a new birth of thought and action as the wind quickens the leaves. There could be no better example than this great ode of the power that Coleridge called "the mystery of genius in the fine arts"—the power "to make Nature thought and thought Nature." Though intellectually divorced from institutional religion, Shelley had the power of faith of the naturally devout. Faith brought him renewed strength, out of which came a fourth act to Prometheus, a hymn of joy that corresponds to the choral finale Beethoven was at this time meditating for his Ninth Symphony.

Here are Earth's great lines about the mission of Man:

> All things confess his strength. Through the cold mass
> Of marble and of colour his dreams pass;
> Bright threads whence mothers weave the robes their children wear . . .

Shelley goes on to what seems almost a prevision of the airplane and the atomic age:

> The lightning is his slave; heaven's utmost deep
> Gives up her stars, and like a flock of sheep
> They pass before his eye, are numbered, and roll on!
> The tempest is his steed, he strides the air;
> And the abyss shouts from her depth laid bare,
> Heaven, hast thou secrets? Man unveils me; I have none.

Nor did Shelley omit to set down some thoughts for more immediate dissemination. In *A Philosophical View of Reform* he urges the rulers that the way to avoid revolution and anarchy is not through bloody repression but through gradual change. As *A Philosophical View* was first published in 1920 it cannot be said that its ideas influenced his countrymen; but since it was in this way that the reforms of the 19th century were achieved in England it must be remembered that Shelley was the precursor, if not the inspirer, of constitutional reform.

A Defence of Poetry (written, 1821; published, 1840) is his most effective prose work. In it he gives a warning of what can happen when "science" progresses more rapidly than the arts and humanities, so that man acquires a mechanical power which he lacks the wisdom to use. Mary Shelley's *Frankenstein* had already given a similar warning. Other thoughts of Shelley's about uses for contemporary science appeared in his scheme in 1819, that *annus mirabilis* of his poetry, for starting a service of the newly invented steamboats between Leghorn and Marseilles.

Epipsychidion, a long poem in rhymed couplets, composed in January 1821 and published anonymously later in the same year, is the culmination of Shelley's quest for the Woman-Symbol. It derives from the situation in a Pisan convent of Emilia Viviani, a young noblewoman whom he believed to be the victim of parental tyranny. He imagines a space voyage with his Platonic love to an enchanted isle, radiant, like the Cave of Asia and Prometheus, with truth, beauty, and freedom. By the spring of 1821 he had turned against both Emilia and his poem. "The error," he wrote, "consists in seeing in a mortal image the likeness of what is perhaps eternal." So much for the ideal that had cost so much to the idealist and to several who loved him.

But close upon this disillusionment came news that roused Shelley to unsurpassed thought and feeling: Keats had died in Rome in February. Quite wrongly, Shelley believed him to have been killed by the stupidity and malice of reviewers. *Adonaïs: an Elegy on the Death of John Keats* (1821) is less a lament for a friend than the elegy of one bard for another. Into Spenserian stanzas adapted in the Greek pastoral style, he poured the accumulated power of philosophic imagery culled from Plato, Dante, and Calderón. The darkness of ignorance has put out a light of poetry: so, at any rate, it seems to us, on our side of the veil, but, asks the poem, how can we judge the reality of the world of eternity by our own transitory world of semblances? Among the poem's images is that of winter passing into spring, by which thoughts of Keats's immortality are joined to Shelley's mood of strength-through-sorrow in October 1819, when the might of the west wind became the symbol both of his own poetry and of the poetic power itself. It is, indeed, in language seeming to borrow the strength of the wind that the elegy on Keats thunders past the miserable, ephemeral reviewer—"Thou noteless blot on a remembered name"—bearing Shelley toward the vision wherein

> The soul of Adonaïs, like a star,
> Beacons from the abode where the eternal are.

No "error" now. Shelley has found "the likeness of what is eternal" symbolized not in a living woman, but in a dead poet.

The year 1821 was concluded triumphantly, with the composition of *Hellas, A Lyrical Drama* (published 1822). This is a paean of joy in which liberated Greece stands for the whole heritage of Western civilization. What new turnings of thought his final masterpiece, "The Triumph of Life," might have had can only be guessed. It was unfinished when, on July 8, 1822, in his little boat, the "Don Juan," he was drowned in a storm off the Tuscan coast. His body was cremated on the shore in the presence of his friends Leigh Hunt, Byron, and E. J. Trelawny (*q.v.*), the Cornish adventurer.

Conclusion.—Shelley believed it to be his special function and ability

> . . . to apprehend minute and remote distinctions of feeling, whether relative to external nature or to the living beings which surround us, and to communicate the conceptions which result from considering either the moral or the material universe as a whole.

This function and ability are shown throughout his major poetry. There must always be many who are unable to apprehend feelings as subtle as Shelley's and conceptions so broad and deep. Many will be attracted to Shelley's poetry by a limited understanding of it. Much that has been written about it is based on misjudgment of the complexities of his life, rather than on true judgment of the complexities of his thought. Shelley's lyrics are much anthologized. Personal, minor poetry for the most part, they have a hard philosophical core which is often unperceived. Their more obvious beauties demand no very high level of understanding, and for this reason they have been disproportionately praised while being anomalously described as "fragile." This critical cliché, combined with Matthew Arnold's biographical one—"the ineffectual angel"—has done much to popularize a distorted impression of Shelley and his poetry. By the mid-20th century, scholarship, in conjunction with the evidence of his manuscripts, had established Shelley as a thinker in advance of his time. His translations, from both classical and modern languages, his power of Byronic wit (in "Peter Bell the Third," for example), and his Aristophanic satire (as in *Swellfoot the Tyrant*) still await the evaluation that is their due. His music and language have influenced many poets. Only Yeats, perhaps, among later poets writing in English, has approached his metaphysic.

Shelley saw himself and contemporary writers as ". . . the companions and forerunners of some unimagined change in our social condition or the opinions which cement it." Among those to whom his ideas have been "companions and forerunners" have been reformers from Robert Owen and William Morris to George Orwell and movements ranging from the Chartists and Fabians to the Ger-

man revolutions of 1848, the beginnings of the Risorgimento, and the anti-Fascist campaigns of Gaetano Salvemini and Lauro De Bosis.

BIBLIOGRAPHY.—*Editions, Correspondence, etc.*: The most nearly complete edition of Shelley's *Works* is the Julian edition, by R. Ingpen and W. E. Peck, 10 vol. (1926–30; reprinted 1965). Of many collected editions of the *Poetical Works* the standard is that by T. Hutchinson (1904; rev. by B. P. Kurtz, 1934). Earlier editions still of value are that of Mary Shelley, with preface and important critical and biographical notes, 4 vol. (1839); and the 2-vol. edition by C. D. Locock, with notes and introduction by A. Clutton-Brock (1911). *See* also C. H. Taylor, *The Early Collected Editions of Shelley's Poems* (1959). Unpublished poems are contained in *The Esdaile Notebook*, ed. by K. N. Cameron (1964); *see* also *The Esdaile Poems of Percy Bysshe Shelley*, critical edition by N. Rogers (1966). *Shelley's "The Triumph of Life,"* by D. H. Reiman (1965), is valuable both as a textual and as a critical study.

Shelley's Prose (excluding letters and the romances) is edited by D. L. Clark (1954). *A Philosophical View of Reform* and *A Defence of Poetry* are included in *Political Tracts of Wordsworth, Coleridge, and Shelley*, ed. by R. J. White (1953). The edition of the *Letters* by F. L. Jones (2 vol., 1964) supersedes that by R. Ingpen (2 vol., 1909; rev. 1914). For Mary Shelley's valuable journal and letters, *see* the bibliography to the article on her.

Life.—Early lives by T. J. Hogg (2 vol., 1858), E. J. Trelawny (*Recollections of the Last Days of Shelley and Byron*, 1858; revised as *Records of Shelley, Byron, and the Author*, 1878), and T. L. Peacock (*Memoirs of Shelley*, in *Fraser's Magazine*, 1858–62; ed., with Shelley's letters to Peacock, by H. F. B. Brett-Smith, 1909), were collected and ed. by Humbert Wolfe, for Everyman's Library (1933). Later biographies include that by E. Dowden, 2 vol. (1886; rev. and condensed, 1896); N. I. White, *Shelley*, 2 vol. (1940; "corrected," 1947; abbreviated as *Portrait of Shelley*, 1945); E. Blunden, *Shelley: a Life Story* (1946); A. M. D. Hughes, *The Nascent Mind of Shelley* (1947). Documents in the Carl H. Pforzheimer Library are chronologically presented in *Shelley and His Circle, 1773–1822*, ed. by K. N. Cameron, 8 vol. (1961–).

Criticism.—See Mary Shelley's critical notes to the edition mentioned above, included in *Keats and Shelley: Complete Poetical Works* (1932); H. N. Brailsford, *Shelley, Godwin and Their Circle* (1913); C. Baker, *Shelley's Major Poetry* (1948); J. A. Notopoulos, *The Platonism of Shelley* (1949); K. N. Cameron, *The Young Shelley: Genesis of a Radical* (1950); N. Rogers, *Shelley at Work* (1956); D. King-Hele, *Shelley: His Thought and Life* (1960). *See* also *The Keats-Shelley Memorial Bulletin*, ed. by D. Hewlett (1950), and *The Keats-Shelley Journal*, ed. by M. Steele (1952–), with annual bibliographies. (N. W. Ro.)

SHELL MOUNDS (KITCHEN MIDDENS; Dan. *kjökkenmöddinger*) are prehistoric refuse heaps or mounds, found distributed throughout the world, that consist chiefly of the shells of edible mollusks intermingled with fragments of animal bones, implements of stone, bone, and horn, and other evidence of human occupancy.

Midden living first developed after the retreat of the glaciers and the disappearance of large Pleistocene fauna hunted by prehistoric man (*see* PLEISTOCENE EPOCH). Primitive peoples adopting these hunting-collecting economies became more settled; thus the oldest pottery of northern Europe, eastern North America, and Central America occurs in shell mounds (*see* ARCHAEOLOGY: *The Materials of Archaeology*).

Many shell mounds have been examined, notably on the eastern coast of Denmark (*see* SCANDINAVIAN ARCHAEOLOGY). Such accumulations indicate seasonal or year-round waterside sites. These were at first thought to be raised beaches, but cursory examination readily indicated their origin in human activities. Further investigation showed these shell mounds to belong to the late Mesolithic Ertebølle culture (*c.* 4000–2500 B.C.). These mounds contained the remains of quadrupeds, birds, and fishes apparently used as food by prehistoric human inhabitants. Among the bones were those of the wild bull or aurochs (*q.v.*), beaver, seal, and great auk, all now extinct or rare in this region. Moreover, shell mounds may contain full-sized remains of the common oyster, which at present cannot live in the brackish waters of the Baltic except near its entrance, the inference being that the shores where oysters flourished were open to the salt sea at the time the mounds were made. Thus also the shells of edible cockle, mussel, and periwinkle that abound in some kitchen middens are of full ocean size, whereas those now living in the adjoining waters are a third of full size for want of salinity. This extension of the North Sea is called the "Littorina Sea." In some places the debris is 10 to 20 ft. deep.

The more recent of these mounds give evidence that their builders had long-range contacts with emerging civilizations of western Asia (yielding remains of cultivated plants, domesticated animals, polished stone implements, and pottery), but incomplete acceptance of the agricultural orientation of the "Neolithic Revolution" (V. G. Childe). The kitchen middens of Denmark apparently were not mere summer quarters: ancient fishermen seem to have stayed in the neighbourhood for much if not all of the year; the mounds contain bones of wild animals that often give reliable clues to fix the time of year when they were killed. Remains of a winter visitor, the wild swan (*Cygnus musicus*), that leaves the Danish coast in March and returns in November, are found in abundance. Additional evidence is found among mammalian remains in the light of such periodic events as the shedding of stag's antlers and the birth and growth of young. Flint implements found include flakes, axes, awls, slingstones or net weights, and rude lance heads. One fragment of a polished axe had been worked into a scraper. Small pieces of coarse pottery are also encountered, typical vessels having pointed bases.

Middens of the British Isles (Oban, Scot., and others), of France (Tardenoisian: Téviec; *see* BRITTANY: *Archaeology*), of Italy, Spain, and Portugal (Asturian, Mugem), and of North Africa (Capsian: Ibero-Maurusian: Mechta, Afalou) also cluster along the Mesolithic-Neolithic transition line. In remote regions like southern Africa (Wilton C) and northern Japan (Jômon; *see* JAPAN: *History*), where Neolithic cultures endured longer, midden accumulations continued until the coming of iron; and in the Pacific islands they accumulated until recently.

In the Americas middens are represented by radiocarbon dates of 5000–2000 B.C. from Panama and eastern North America (*see* GEOCHRONOLOGY). Middens of Brazil, Argentina, northern Chile, Peru, and California probably antedate 2000 B.C. As in the Old World, midden living persisted outside the high civilizations, continuing in California, Florida, West Indies, and Patagonia until European conquest.

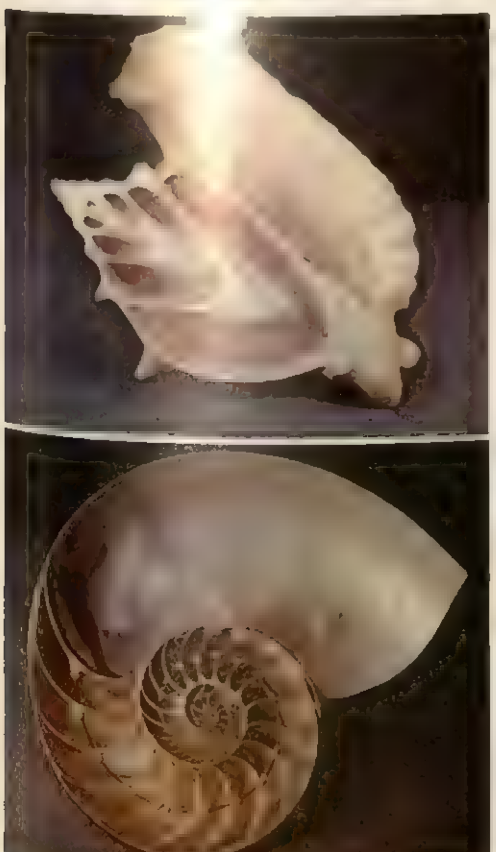
SHELLS AND SHELL COLLECTING. Shells of mollusks, because of their bright colours, rich variety of shapes and designs, and abundance along sea shores, have probably from the earliest times attracted the attention of man. He used them for ornaments, tools and coin, and dined on the mollusks that formed them. Aristotle and Pliny wrote extensively about them. In the ruins of ancient Pompeii and in a crypt in a Mayan pyramid in Yucatán shells were found that may well be the remains of ancient collections.

Shell collecting as we understand it today, however, on the same plane as coin, stamp and china collecting, is of quite recent origin. Shell collecting reached its apex in England during the late 18th and early and middle 19th centuries. This was the period of the burgeoning Pacific and China trade; new islands were being discovered and the shells found there were first imported as curiosities, later as specimens for the collectors among the newly rich merchant princes. This period reached its highest point in the 1850s and '60s when shell auctions became a common occurrence and relatively high prices were paid for particularly rare and perfect specimens. There followed a period of relative decline, probably because many formerly rare shells suddenly became common as their haunts were discovered and exploited. The shells were then dumped on the market and the prices suffered a sudden decline. An example is *Voluta junonia* of Florida which fetched $50 or $60 for choice specimens when that state was still relatively unexplored and difficult of access. Then when Florida became one of the nation's winter playgrounds and *V. junonia* was collected in large quantities, the price fell rapidly until superb specimens brought no more than $5. This drop happened in hundreds of other cases too.

Nevertheless, shells are so strikingly interesting and beautiful in themselves that the hobby was rapidly revived. The U.S. troops stationed on lonely islands in the Pacific after the fighting

Shells of unusual shape [illegible] Spindle shell, *Tibia fusus* (Philippines); (2) *X*[illegible] *pallidula* (Japan); (3) *Murex tenuispina* (Ry[illegible]ands); (4) *Brechites radix* (Torres strait); (5) [illegible] *bednalli* (Australia); (6) *Trophon triangulatus* [illegible]rnia); (7) *Malleus albus* (Japan); (8) *Arca to*[illegible] (China); (9) Bubble shell, *Hydatina albocincta* [illegible] (10) *Latiaxis deburghiae* (Japan); (11) *Terebr*[illegible]*ata* (Japan); (12) *Murex pele* (Hawaii); (13) *An*[illegible]*pis hirasei* (Japan)

Florida shells: (1) Sunrise tellin, *Tellina radiata;* (2) Thorny oyster, *Spondylus americanus;* (3) Lace murex, *Murex florifer;* (4) common sea snail, *Janthina janthina;* (5) Long-spined star-shell, *Astraea longispina;* (6) Fargo's worm shell, *Vermicularia fargoi*



Left: Cross sections of the common giant conch, *Strombus gigas* (above) and the chambered nautilus, *Nautilus pompilius*

Below: The ear shell or abalone, *Haliotis,* found on the California coast. Exterior of shell is shown at top left; polished exterior after outer coating has been removed is shown at right. The inside of the shell, bottom left, shows the mother-of-pearl lining. Holes in the shell are used for breathing by the abalone

had moved on learned to gather shells to while away the time. Stay-at-homes became interested in shells and soon the hobby began to rival stamp and coin collecting in popularity. Shells, because of their beauty and exotic points of origin, will long cause large numbers of persons to be interested in them.

The shell itself is the exoskeleton (external skeleton) of a soft bodied animal that secretes it to serve as protection as well as support for its various organs. The animal is bound securely to the shell and can no more survive separation from it than we can from our bony framework. After a mollusk has died other marine animals may become occasional inhabitants of the shells. Such an animal is the hermit crab, which makes use of the shell as a temporary abode. Most marine mollusks are able to shut themselves off completely from their watery world when they find themselves in danger, by closing their aperture by a horny or calcareous door, or operculum. The careful collector makes it a point to preserve the door with the shell in his collection.

The rarest, the most valuable, and in many senses the most beautiful shells are those that are found in the sea, but large numbers of species live only on land or in fresh water. The aristocrats of the shell world are the various members of the families Cypraeidae (cowrie shells), Conidae (cone shells), Volutidae (volute shells), and Muricidae (rock shells). One of the rarest and most desirable single species is *Conus gloria maris*, the glory of the sea. This is a handsome cone shell, of which only about 30 exceptionally beautiful specimens have ever been known. They always command a very good price on the market—$1,250 in 1957. It is also the only shell known to have been stolen from a large museum.

The question might be asked: why are some shells rare, others relatively common, and still others exceedingly abundant? The answer is intimately bound up with the habits of mollusks. Many species can tolerate only the conditions of life that are found in the intertidal zone on sandy or rocky shores. Such shells are most easily collected, since one need only wait for a low tide to begin gathering them. In the intertidal zone some very handsome shells are found, *e.g.*, the glistening, richly coloured Olividae (olive shells), the Naticidae (moon shells), and Strombidae (strombs) as well as Terebridae (augur shells) and many bivalves (clams) that burrow in water-soaked sand. On the rocks and under them are found Littorinidae (periwinkles), Turbo (turban shells) and limpets, as well as the Chitonidae (pill bug or coat of mail shells) that have the curious habit of curling up like the land crustacean (pill bug) for which they are popularly named.

Other shells live only in the shallow water below the extreme low tide line. These shells are washed up on the beach after storms. Since luck and some degree of effort—dredging or straining—is involved in capturing them, they tend to be scarcer and more costly than the intertidal species.

The really rare shells are species that can live only in deep water. There live the rarest and costliest volutes, cones, cowries and rock shells. They can be obtained only by expensive and difficult deep-sea dredging operations from specially designed ships. Such shells would be quite unavailable to the average collector if he had to depend only upon these sources for his specimens. Luckily, however, they are frequently obtained as a side line in shrimp or fish dredging. Many fishermen, especially in Japan, have discovered that selling shells can supplement their regular incomes. They keep the shells on board instead of discarding them with the muck that their dredges bring up and sell them to dealers or collectors. Some of our greatest rarities, such as *Busycon coarctatum* (the turnip shell) are obtained in this manner.

Another source of deep-water shells are fish stomachs. Many ground-feeding fish species such as haddock and cod are frequently caught with their stomachs full of nicely cleaned and faultless shell specimens. A few rare shells such as the costly *Cypraea fultoni* (Fulton's cowrie shell) are known only from this sort of "habitat," *ex pisce* as the scientist puts it. SCUBA and skin divers bring up many rare specimens from depths up to 30 ft. Many shells that hide regularly in coral crevices can be collected in no other manner.

Although most mollusks live in the sea, many colourful species are air-breathing land dwellers. These shells are found everywhere that their few simple requirements of shade, moisture and food (usually plant or fungi) are satisfied. The largest majority are tiny (some only a few millimetres in size) and quite plain looking. They excite the interest of only the dedicated scientist or the enthusiastic amateur collector who makes a specialty of the shells of special regions. Some of these shells, however, are brightly coloured, large and quite showy. Best known are the *Liguus* (tree snail) of southern Florida and Cuba, *Papuina* of Papua, *Helicostyla* of the Philippines and the very large *Achatina* of Africa. These shells are not so popular among most enthusiasts as are marine shells because few collectors are willing to undergo the discomforts and dangers of collecting them. The tree snail of Florida shares its habitat with diamondback rattlers and cottonmouths, as well as voracious mosquitoes; *Papuina* and *Helicostyla* are found on trees in hot malarial regions haunted by savage headhunters; the ground-dwelling *Achatina* of Africa frequently live in the very heart of the continent.

The shells that live in fresh water are even less popular with collectors, chiefly because none of them are colourful, and only very few have any claim to beauty. The river mussels of the midwestern United States have a beautiful internal pearllike covering, or nacre, and are sometimes handsomely ornamented with tubercles and wavy ridges. They are often sold in bulk to button manufacturers. Few if any command a respectable price per specimen. Their slight claims to beauty are further impaired by the erosion of the shell caused by acids in solution. Fresh-water snail shells are of considerable interest to the student of tropical diseases, since some snails serve as unwilling hosts of severe human and animal diseases.

One of the pleasantest aspects of shell collecting is that the shells need little service to be stored. They do not require the careful attention and handling necessary in a butterfly, beetle or herbarium collection. They are not as heavy as minerals. They are not subject to insect or fungus attack. Once the shell is reasonably well cleaned and provided with a complete label, it can remain unaltered for years in the drawer or cabinet to which it has been consigned.

Most collectors tend to specialize, since they realize very soon that their chance of obtaining even a fair proportion of the about 100,000 shell species known is very slight. Most collectors confine their interest to the aristocrats mentioned earlier. Others limit themselves to localities, collecting only the shells of Florida or California or even more immediate locales. Such specialists frequently contribute valuable scientific data in the form of exact locality records and observations on life habits of many mollusks. Another type of collector gathers only specimens of the type genus of shells, that is the single species of a shell that characterizes a particular genus. Such a collection is a valuable lesson in taxonomy and evolution and gives a perspective view of the entire field of conchology, the study of shells.

There are also specialists in land shells. Land shells have the virtue of being less bulky than marine shells and lend themselves to easier storing. They are also less expensive than marine shells, and complete family or generic collections can be made at low cost. The *Liguus* enthusiasts are a class apart, and in their zeal for completeness of their collections are sometimes ready to pay respectable prices for particularly desired specimens.

Shell collecting also can form the base for many interesting studies. All stamps and coins of the same type are machine made and therefore identical; however, like all living organisms, no two shells are exactly alike. Many an amateur has become interested in the variations of a single species and has often accumulated so much data that he could prove that what were considered two distinct and valid species are actually only the extreme variations of a single species. This aspect adds an element of excitement to shell collecting that is not found in many other collecting hobbies. In fact, many of the best-known scientists in the field of conchology began as amateur shell collectors.

A word might be said about the equipment of the shell collector. All that most collectors use are a basket or a small quantity of bags and small boxes; some sort of tool to scrape away

the sand or leaves; a knife to detach rock clingers from their perches; a hammer and chisel to remove rock borers from their nests; a sieve to strain out specimens from shallow water; a notebook to record locality and ecological data and a stout back for much stooping. In addition there should also be a library of books on shells, limited only by financial means and availability of the classics of the shell world. These books, together with recourse to museum collections, are the only sources of the proper Latin names for shell species.

SHELL SHOCK, a nonspecific term applied to World War I combatants suffering from the condition that was generally called combat fatigue in World War II. *See* COMBAT FATIGUE.

SHELTON, THOMAS (fl. 1612–1620), English translator of *Don Quixote,* seems to have been employed by Theophilus Howard, 2nd Baron Howard de Walden and afterward earl of Suffolk, to whom he dedicated *The History of the Valorous and Wittie Knight-Errant Don Quixote of the Mancha* (1612). In his dedication he states that he did the work "in the space of fourty dayes" at the request of "a very deer friend." Shelton did not use the original edition of Cervantes (1605) but that published at Brussels in 1607. On the appearance of the Brussels reprint of the second part of *Don Quixote* in 1616 he translated that into English also, and published it in 1620 with a revised version of the first part.

Shelton's version is the happiest English translation of the great Spanish classic, combining robust vigour with grace and ease. It is possible that the translator was the Thomas Shelton who wrote the sonnet prefixed to *A Restitution of Decayed Intelligence* by Richard Verstegan (1605).

Shelton's *Don Quixote* was edited by J. F. Fitzmaurice-Kelly, four volumes (1896), A. W. Pollard (1900), and F. J. H. Darton (1923).

SHELTON: *see* ANSONIA.

SHEM was the eldest of Noah's three sons (Gen. v, 32; x, 1). In the Old Testament genealogical tables tracing the origins and connections of the various peoples, the Hebrews, Aramaeans and Arabs are counted among the descendants of Shem, and from the name is derived the adjective Semitic. Certain other peoples (as the Elamites) are referred to also as his descendants, on a geographical or political rather than linguistic basis. Roughly speaking, the nations supposed to share Shem as their ancestor lie geographically between the descendants of his brothers Japheth (*q.v.*), on the north, and those of Ham (*q.v.*) on the south.

SHEMA (Heb. "hear"), the initial word of the scriptural verse "Hear, O Israel: the Lord our God is one Lord" (or ". . . the Lord our God, the Lord is One"; Deut. 6, 4), the watchword of Jewish faith. It is chanted at various points of the Jewish liturgy and recited mornings and evenings as a part of a text that includes Deut. 6:4–9 (defined as "the acceptance of the yoke of the kingdom of God"), 11:13–21 ("the acceptance of the yoke of the commandments"), and Num. 15:37–41 ("the remembrance of the redemption from Egypt"). It is inscribed on certain ritual objects. Following the example of the Palestinian sage and martyr Rabbi Akiba (2nd century A.D.), the Shema is uttered by the Jewish martyrs through the ages as the final profession of faith in the one God of mankind and of love for him. This theme was variously elaborated by medieval liturgic poets. *See* further LITURGY, JEWISH.

SHENANDOAH NATIONAL PARK, in Virginia, U.S., was established in 1935 to preserve 193,646 ac. (78,369 ha.) in the Blue Ridge Mountains. The most easterly of the Appalachian ridges, the Blue Ridge is geologically ancient, and has been eroded to its present elevation through countless thousands of years. (*See* APPALACHIAN MOUNTAINS.) In general, mountain profiles are rounded, but rocky outcrops and precipitous ledges appear in a few places, such as on the highest point, Hawksbill Mountain, 4,049 ft. (1,234 m.) above sea level, on Old Rag Mountain and at Franklin Cliffs.

The park is noted for its scenery, which affords some of the widest views in the eastern states. Skyline Drive runs the length of the park, winding among the summits, dipping through highland valleys and gaps for about 105 mi. (170 km.), from the town of Front Royal on the north to Jarman Gap on the south. Except for a few grassy meadows along the crest, the park is heavily forested with hardwood trees, including black gum, yellow, gray and black birches, linden, tulip tree, and several species of oak. Among the conifers are eastern hemlock, Virginia, white, Table mountain, and pitch pines, red spruce, and, on the highest peaks, Fraser fir. Wild flowers typical of eastern woodlands are abundant. In spring, from April to June, there is a succession of blooms—redbud, flowering dogwood, azalea, and mountain laurel—and in autumn a display of brilliant foliage. White-tailed deer, bobcat, red and gray fox, and gray and flying squirrels inhabit the park, and the greatest number of bird species occurs in spring, when such migrants as rose-breasted grosbeak, brown thrasher, towhee, scarlet tanager, and numerous warblers arrive to make their summer homes.

This park is joined to Great Smoky Mountains National Park (*q.v.*) by the 470-mi. (756 km.) Blue Ridge Parkway. (Dx. B.)

SHENANDOAH VALLEY, in Virginia, U.S., extends southwest from the vicinity of Harpers Ferry on the Potomac River and lies between the Blue Ridge Mountains and the Alleghenies. It is a part of the Great Valley of Virginia. In a narrow sense the Shenandoah Valley embraces only nine counties drained by the Shenandoah River: Berkeley and Jefferson in West Virginia, and Frederick, Clarke, Shenandoah, Warren, Rockingham, Page, and Augusta in Virginia.

In popular usage, however, the Shenandoah Valley extends to the James River and includes Rockbridge County: it is approximately 95 mi. (153 km.) long and averages 25 mi. (40 km.) in width. From the floor of the valley near Harrisonburg rises Massanutten Mountain, which stretches to the northwest for 50 mi.; it divides the two forks of the Shenandoah River. Among the historic passes through the Blue Ridge are Swift Run Gap and Rockfish Gap.

The valley was once inhabited by Indians of the Tuscarora and Shawnee tribes whose Indian road ran the length of the valley. The road became the famous Valley Pike, a main artery in the westward movement, and is now a U.S. highway. In 1707 Louis Michelle explored the lower valley, and in 1716 Gov. Alexander Spotswood led an expedition over the Blue Ridge to the Shenandoah River. Settlement of the valley by white men began about 1730; at this time buffalo and elk abounded. Most of the early settlers, German Lutherans and Scotch-Irish Presbyterians, came from Pennsylvania, though some English came across the Blue Ridge. The various national groups usually settled in separate communities. In antebellum days the Shenandoah Valley was a region of family-operated farms and few slaves. During the Civil War "Stonewall" Jackson won immortality by his "Valley campaign" (*see* JACKSON, THOMAS JONATHAN). Near the end of the conflict the valley was devastated by Federal forces.

The backbone of the valley's economy is agriculture, with emphasis upon purebred cattle, sheep, poultry, and dairy farming. Harrisonburg is a turkey capital and Winchester is noted for its apple orchards. Industry has enjoyed a remarkable growth with carpets, chemicals, cutting instruments, electric appliances, and rubber goods being particularly important. The native limestone is suitable for building. The labour force tends to commute from rural areas instead of moving to mill towns.

Colleges in the valley include Madison in Harrisonburg, Mary

Baldwin in Staunton, and Virginia Military Institute and Washington and Lee University in Lexington. There are numerous military preparatory schools in the area and many summer camps.

Large numbers of tourists are attracted by the Skyline Drive and Blue Ridge Parkway (both on the crest of the Blue Ridge), the Shenandoah National Park (*q.v.*), the Natural Bridge, near Lexington, and many limestone caverns. (G. M. BE.)

SHENANDOAH VALLEY CAMPAIGNS. In the American Civil War (*q.v.*) the Shenandoah valley was often the scene of military operations, some of them of considerable importance. This valley lies between the Blue Ridge and the Allegheny mountains. The river from which it takes its name rises below Lexington, Va., and flows 155 mi. to Harpers Ferry where it enters the Potomac river. It is part of the great valley that extends on up into Maryland and Pennsylvania providing a well-sheltered route for invading the North. On the eastern side of the valley a series of gaps opens the way through the Blue Ridge mountains to the Piedmont plateau. The low Massanutten mountain rises abruptly from the floor of the valley for about 50 mi. between Strasburg and Harrisonburg, affording excellent opportunities for military maneuvering. The inhabitants of the valley were mostly southern in their loyalties, making it an important recruiting ground as well as a rich source of cattle and grain.

The valley was more useful to the Confederates than to the Federals. Movement up and down, and in and out on the eastern side, was made easy by a network of good roads connecting all the towns and running through the several gaps into eastern Virginia. In the upper part of the valley two railroads served Richmond and at the northern end the Baltimore and Ohio railway, connecting Washington, D.C., with the west, ran along the line of the Potomac river. Whenever a Confederate army moved north it drew nearer to Washington, but when a Union army moved up the valley it was pulled away from Richmond. When a southern army crossed the Potomac it cut across the Baltimore and Ohio railroad and was 60 mi. N. of Washington. Hence the presence of a Confederate army in the northern part of the Shenandoah valley was often considered a sufficient menace to justify calling back troops from campaigns elsewhere to ensure the security of the capital. The southerners used the advantages offered by the valley so effectively that it often became for the North the "valley of humiliation" until late in the war when the Union forces took undisputed control.

The initial campaign of the war in the east turned on the use of forces posted in the lower valley. In July 1861, when the Federal invasion of Virginia began, this Shenandoah army united with the forces of *Gen. P. G. T. Beauregard* on the field of Bull Run (*q.v.*) in time to meet the attacks of Gen. Irvin McDowell and turn the tide in favour of the southerners. (To aid the reader the names of Confederates are put in italics.)

In the spring of 1862 when Gen. George B. McClellan was advancing up the Yorktown peninsula toward Richmond, instead of calling *Gen. T. J. "Stonewall" Jackson* from the Shenandoah to the defense of Richmond, *Lee* sent *Gen. Richard S. Ewell* with reinforcements so he could threaten Washington. Operations in the valley opened with *Jackson* retiring from Winchester on March 12, and Gen. N. P. Banks with 20,000 Union troops taking possession. Banks then sent Gen. James Shields on to Strasburg and a week later *Jackson* withdrew his small force to Mt. Jackson. When Banks recalled Shields, *Jackson* followed him, but Shields turned on him at Kernstown and defeated him with a force that outnumbered his two to one. Banks then decided to drive *Jackson* from the valley, but *Jackson* took refuge in the passes of the Blue Ridge where he could await reinforcements and a favourable opportunity to fall upon the Federals. In May, leaving *Ewell* to watch Banks, *Jackson* proceeded secretly by rail through Rockfish Gap with the remainder of his command to join *Gen. Edward Johnson's* brigade, then beset by Gen. Robert H. Milroy west of Staunton, and together they claimed their first victory on May 8. Meanwhile Banks's army near Strasburg had largely been sent elsewhere, and *Jackson* moved quickly through Luray valley on the east side of the Massanutten mountain. He surprised part of Banks's army at Front Royal on May 23 and followed the retreating Banks through Winchester, driving him across the Potomac. At this turn of events, Washington authorities rescinded the order for McDowell's corps at Fredericksburg to join McClellan. McDowell was ordered to send Shields to converge with Gen. John C. Frémont's troops in the southwestern part of the valley and intercept *Jackson's* army as it returned. *Jackson* had luck, a good road and *Ewell's* division to slow up Frémont. The result was that the Confederates were able to defeat Frémont on June 8, at Cross Keys, and were also able to cross the valley to intercept and defeat Shields at Port Republic the next day. *Jackson* then went on to aid *Lee* and the main army before Richmond, and Lincoln recalled the divisions of Frémont, Banks and McDowell, leaving the valley at peace for a time.

When *Lee* entered Maryland in the campaign that was to reach its climax at Antietam (*q.v.*) in Sept. 1862, he expected the Federals to leave Harpers Ferry to defend Washington. When they failed to do so, he planned while moving to Hagerstown to take Harpers Ferry and reopen communications with the Shenandoah valley. *Jackson* marched with three divisions to invest the town from the rear, another division took up a position on Maryland Heights overlooking Harpers Ferry from north of the Potomac, while a fifth climbed Loudon Heights across the Shenandoah from the city. Surrounded and subject to a triple fire the Federals surrendered and *Jackson* rejoined *Lee*.

The concentration of Federal forces in northern Virginia in May of 1864 in preparation for Gen. U. S. Grant's advance upon Richmond from the north involved a fresh series of operations in the

BY COURTESY OF THE LIBRARY OF CONGRESS

BATTLE OF WINCHESTER, VA., MARCH 23, 1862; A PENCIL DRAWING BY A. R. WARD WHICH APPEARED IN "HARPERS WEEKLY," APRIL 12, 1862

valley. The Confederates defeated a containing force there under Gen. Franz Sigel. Sigel was replaced by Gen. David Hunter who was to co-operate with Grant's army of the Potomac. Grant sent Gen. Philip H. Sheridan with the cavalry to cut the valley's communications with the Confederate capital, but *Gen. J. E. B. Stuart* stopped him at Yellow Tavern, losing his life in the encounter. *Lee* then sent *Gen. Jubal A. Early* to the valley once again to remove the pressure on Richmond by threatening Washington. *Early* was as famous in his way as *Jackson*, the other great Confederate leader in the valley campaigns. He was an aggressive fighter, an exponent of the quick march and the audacious action later to be associated with the blitzkrieg. Grant detached Sheridan to join Hunter at Charlottesville, but *Lee* sent *Gen. Wade Hampton's* cavalry to intercept him and compel him to return and leave Hunter to his fate. To divert northern troops from *Lee's* front, *Early* drove Hunter out of Virginia by the Kanawha river route and moved down the valley unopposed. He crossed the Potomac, reached Hagerstown and Frederick in Maryland and on July 11 led 8,000 men past Silver Spring, Md., and into sight of the U.S. capital. Though he frightened official Washington he made no attempt to take the city.

This raid added insult to injury. Grant therefore sent Sheridan to clear the valley of Confederates by intercepting *Early* on his return from Maryland, or, failing that, to drive him up the valley and to destroy all the supplies he could not use himself. Sheridan made Harpers Ferry his headquarters and on Aug. 10 moved out in strength, only to find that *Early* was also reinforced. In a series of encounters beginning on Sept. 19 near Winchester, and shortly after at Fisher's Hill, he drove *Early* back to Mt. Jackson and finally defeated him, but not without one more reminder of the "valley of humiliation." After the victory at Fisher's Hill, Sheridan retired to Winchester apparently feeling that *Early* would trouble him no more. But *Early* followed him to prevent his sending aid to Grant at Petersburg. Two of the three corps of Sheridan's army were routed in a well-planned and well-executed attack at Cedar creek but *Early* failed to follow up and complete his victory. Sheridan was absent from the first part of the fighting but returned to the scene in time to rally his forces, attack and drive back the Confederates, recovering all the ground lost and recapturing his abandoned guns and baggage. *Early* then retreated up the valley to Waynesboro where, on March 2, 1865, he suffered the defeat that ended Confederate resistance in the valley. Sheridan meanwhile had destroyed supplies and communications in the valley in a manner reminiscent of Gen. W. T. Sherman's march through Georgia and the Carolinas.

See J. Davis, *The Shenandoah* (1945); D. S. Freeman, *Lee's Lieutenants*, 3 vol. (1942–44). (C. W. Te.)

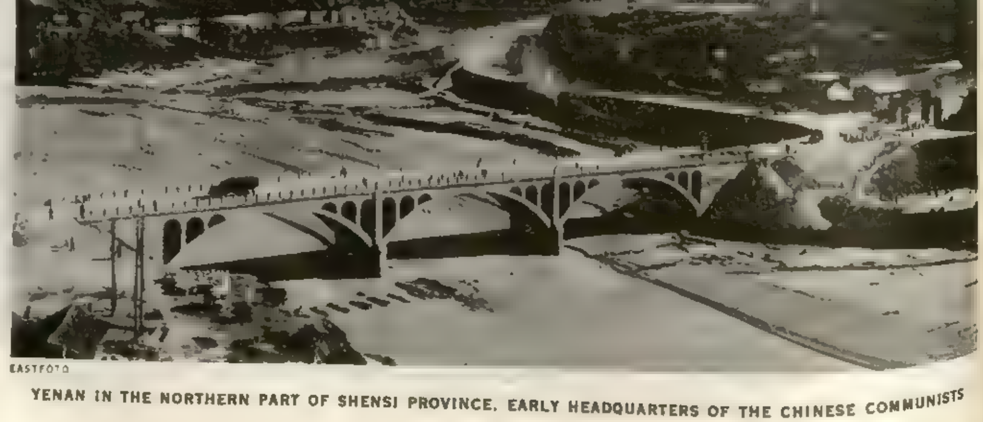
SHENSI (Shen-hsi Sheng) is a northwest province in the loesslands of China between Kansu and Shansi provinces. It was one of the earliest seats of Chinese civilization, the site of a historic capital centred in the vicinity of Sian (*q.v.*), the present provincial seat. Area 75,598 sq.mi. (195,800 sq.km.); pop. (1957 est.) 18,130,000.

Topographic barriers and the fertile productivity of the well-watered Wei Ho (river) Plain supported its command over strategic gateways to central Asia in the northwest, Inner Mongolia in the north, Szechwan across the Tsinling Shan in the south, and the Yellow River Plain in the east. Shaped in a slender wedge 300 mi. (480 km.) long east and west, the Wei Ho Plain begins with a width of about 1 mi. at Pao-chi in the west and widens near Sian to 30–40 mi., continuing thus to the fortress city of T'ung-kuan at the Yellow River elbow. Northward the land rises through a region of deeply gullied badlands to plateau remnants 3,000–6,500 ft. (900–2,000 m.) high near the Ordos Desert and eastern Kansu. Halfway between the Wei Ho and the Ordos Desert lies the town of Yenan, the Chinese Communist capital from 1935 to 1949. In the east, the land overlooks the deep gorge of the Yellow River which drops turbulently there and is only about 330 ft. (100 m.) wide through much of its course until Lung-men is reached. From there to T'ung-kuan the river broadens to 1–2 mi., then turns and leaves the province to flow eastward. Southward of the Wei Ho, the northern front of the Tsinling Shan rises abruptly from the plain, mantled with the same yellow loess on its northern slopes as that covering northern Shensi. Southern Shensi comprises the south slopes of the Tsinling Shan and the north slopes of the Ta-pa Shan and represents an entirely different landscape. Between them in the Han Shui Valley lies the Han-chung Basin, about 50 mi. long by 6 mi. wide.

North and south Shensi have greatly differing climates. The Tsinling Shan blocks the cold winter winds from moving south, while it greatly reduces the moisture in summer winds moving north. Thus in winter the Han-chung Basin is mild and damp, while northern Shensi is cold and dry. Precipitation reaches a yearly average of 30 in. (760 mm.) south of the Tsinling Shan where the annual average temperature is 15° C (60° F), similar to that of Szechwan. By contrast, the Wei Ho plain gets under 20 in. (510 mm.), while in the north this is reduced to as little as 4 in. The January average at Sian falls to 0° C (31° F), while at Yu-lin in the extreme north it falls to −7° C (17° F). July averages at these two cities are 27° C (82° F) and 23° C (75° F) respectively. The autumn rainfall concentration is combined with great fluctuations in annual amounts and seasonal occurrences, presenting great farming hazards. Canal and well irrigation is practised where possible.

The Wei Ho Plain, the economic heart of the province, is especially noted for winter wheat and summer cotton production. In the north, spring wheat and millet are significant crops. Beans, kaoliang, corn, and tobacco also are grown. In the Han-chung Basin, paddy rice in summer is followed by winter wheat. Fruits grown include pears, apples, apricots, and grapes. Farm sidelines include the raising of sheep, horses, donkeys, mules, goats, and pigs. Forest remnants exist in the heights of the Tsinling Shan, but north Shensi is rather barren and brown. Sand encroachment from the Ordos Desert in the north is countered with planted shelter belts.

Shensi has important coal deposits which are largely located in the drainages of the Ching and Lo rivers. Petroleum is being



EASTFOTO

YENAN IN THE NORTHERN PART OF SHENSI PROVINCE, EARLY HEADQUARTERS OF THE CHINESE COMMUNISTS

exploited in the Yen-ch'uan and Yen-ch'ang districts. Oil shale occurs in the Han-chung Basin. Alluvial gold is panned in the streambeds of the upper Chialing Chiang and the south-slope rivers of the Tsinling Shan. Salt is obtained from lakes in the Wei Ho Plain. Manganese and graphite also are mined in the province.

Cotton manufacturing is an important industry at the chief cities of Sian, Hsien-yang, Pao-chi, and Han-chung. Sian is the major industrial, cultural, and political centre. The Lunghai Railroad from Honan follows the Wei Ho Plain westward into Kansu. From Pao-chi on this line, a railroad crosses the Tsinling Shan to Szechwan. Highways radiate from Sian to Yenan and Yu-lin in the north, Kansu in the west, and Honan in the southeast. A highway also crosses the Tsinling Shan from Pao-chi.

Much industrial progress has taken place since the Communists consolidated their power and took control. In the 1960s output of electric power, coal, and crude oil was reported to be much higher than before 1949. Many other new industries were introduced, including textile plants, flour mills, and brick factories.

(H. J. Ws.)

SHENSTONE, WILLIAM (1714–1763), English poet, essayist, landscape gardener, and arbiter of taste, who was a key figure in the movement away from Augustan poetry and aesthetics (*see* ENGLISH LITERATURE: *The 18th Century*). Born on Nov. 18, 1714, at the Leasowes, Halesowen, Shropshire, he was educated at the village school, whose "dame," Sarah Lloyd, he celebrated in "The School-Mistress," and at Solihull. In 1732 he entered Pembroke College, Oxford. In 1735 he inherited the Leasowes, and from 1745 devoted his income of £300 a year to making it what he described as a "*ferme ornée*" (*i.e.*, an ornamented, but still useful, farm), blending classical elegance with early Romantic sensibility. His ideas on landscape gardening (a term he was the first to use) are explained in "Unconnected Thoughts on Gardening": "landscape should contain variety enough to form a picture upon canvas . . . Objects should . . . be less calculated to strike the eye than the judgment or . . . imagination."

WILLIAM SHENSTONE, DETAIL OF A PAINTING BY E. ALCOCK

"The School-Mistress," Shenstone's most famous poem, one of the earliest 18th-century imitations of Spenser, uses the Spenserian stanza with delicate humour. Included in his *Poems on Various Occasions* . . . (1737), it was expanded in 1742 and 1748, when it appeared in Robert Dodsley's *Collection* . . . (vol. i, 2nd ed.). Of the later volumes Shenstone became, in effect, editor. "A Pastoral Ballad," with its fresh, lyrical measure, appeared in vol. iv (1749), and many other of his verses in vol. v (1758). He was frequently consulted, and his influence is revealed in his correspondence—notably that with Bishop Thomas Percy (*q.v.*), proving that Shenstone's collaboration in *Reliques of Ancient English Poetry* (1765) amounted to co-editorship. He helped to revive the ballad (*q.v.*), and established easy lyrical movement and rural simplicity as criteria for poetry, foreshadowing many of the preoccupations of Romanticism (*q.v.*). He edited a poetic miscellany to illustrate his theories, but died (Feb. 11, 1763, at the Leasowes) before he had submitted it to his friend John Baskerville for printing. It remained in manuscript until 1952. His *Essays on Men and Manners* (1764) is notable for its development of the maxim, or *pensée*, and, as Dodsley said, shows "the acuteness of his understanding and his profound knowledge of the human heart."

BIBLIOGRAPHY.—*The Works in Verse and Prose* . . . , ed. by R. Dodsley, 2 vol. (1764), vol. iii (1769) adds *Letters to Particular Friends. The Letters*, ed. by M. Williams, and by D. Mallam (both 1939); *Shenstone's Miscellany, 1759–1763*, ed. by I. A. Gordon (1952); *Men and Manners*, ed. by H. Ellis (1927). Johnson's *Life of Shenstone* (1781) fairly assesses his poetry, but ridicules him as a person; R. Graves, *Recollections of . . . . Shenstone* (1788), presents a fairer assessment. *See* also M. Williams, *William Shenstone and his Friends* (1933), *William Shenstone* (1935); A. R. Humphreys, *William Shenstone* (1937).

(I. A. G.)

SHEN-YANG: *see* MUKDEN.

SHEOL, in the Old Testament, one of several names used to designate the abode of the dead; it is the commonest of these names, being used 66 times. The exact meaning of the term is not known, though it appears to have some connection with necromancy; that is, revealing the future through communication with the dead. *See* also HELL: *Judaism*.

SHEPHERD, JOHN (*c.* 1520–?), English composer of sacred music. In 1542 he succeeded Thomas Appleby as instructor of the choristers at Magdalen College, Oxford. He appears to have resigned in 1543, to be replaced by Thomas Preston, but in 1545 he was reappointed, this time remaining, apparently, for two years. In 1552 he was made a Gentleman of the Chapel Royal and continued so under Queen Mary, being described in several manuscripts as "of the queen's chapel." In 1554, however, he was again in Oxford, supplicating for the degree of doctor of music and described as a student of music for 20 years. In June 1555 he was in trouble with the authorities of Magdalen College over two incidents that reflect unpleasantly on his character; in 1557 he was once more at the Chapel Royal. The date of his death is unknown. A substantial quantity of Shepherd's music for both the Latin and the English rites remains. It embraces a variety of liturgical forms including five complete Masses, antiphons, responds, hymns, psalm-motets, troped lessons, processionals, English services, anthems, and keyboard pieces. The quality of his work suggests a reason for the tolerance with which his employers seem to have regarded his restless instability. One of the manuscripts containing his setting of *Haec dies* bears the annotation "a good songe, an excellent good songe" and "the best songe in England."

(Jo. D. B.)

SHEPPARD, JOHN (JACK) (1702–1724), English criminal, became famous for his daring escapes from Newgate Prison. Many tracts and plays were written about him, and *A Narrative of all the Robberies, Escapes . . . of John Sheppard* (1724) is attributed to Daniel Defoe. Sheppard was made the hero of much romance, notably in Harrison Ainsworth's novel, *Jack Sheppard* (1839).

He had a short career. He was born at Stepney, near London, on March 4, 1702, the son and grandson of carpenters, was brought up in the Bishopsgate Workhouse, and in April 1717 was apprenticed as a carpenter by one of his father's employers. At a neighbouring Drury Lane tavern, in 1723, young Sheppard met Elizabeth Lyon, known as "Edgeworth Bess," a woman with whom he lived. To gratify her tastes, he committed many of his crimes. At the end of 1723 he was arrested as a runaway apprentice, and thenceforward he said "I fell to robbing almost everyone that stood in my way." Joseph Blake, known as "Blueskin," was a frequent accomplice.

In the first six months of 1724 he twice escaped from prison, and toward the end of that period he was responsible for an almost daily robbery in and around London. Eventually, however, his independent activity provoked the bitter enmity of Jonathan Wild, controller of a large criminal organization, who procured his arrest on July 23.

Sheppard was tried at Old Bailey on Aug. 13 and condemned to death. Largely thanks to Edgeworth Bess he managed to escape from the condemned cell on Aug. 31, and was soon back in his old haunts. Rearrested on Sept. 10, he was imprisoned in the strongest part of Newgate, where he was handcuffed and chained to the floor. By a combination of skill and strength he freed himself and, after climbing through the chimney to the room above, forced five doors and lowered himself from the prison roof into an adjoining house. After a few days concealment he reappeared in the Drury Lane quarter, where he was recaptured, hopelessly drunk, in a

Clare Market tavern on Oct. 31. He was again taken to Newgate, and this time his cell was watched night and day. He was hanged at Tyburn on Nov. 16, 1724, before a crowd estimated at 200,000.

See H. W. Bleackley, *Jack Sheppard*, ed. by S. M. Ellis (1933); C. Hibbert, *The Road to Tyburn* (1957).

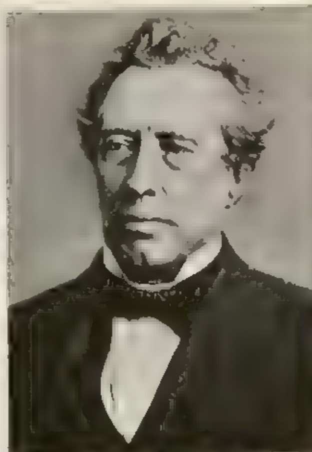
SHEPPEY, an island off the Kentish coast of England, the largest of several low islands separated from the mainland by the ramifying creeks about the mouth of the Medway. The Kingsferry road and rail bridge over the Swale is the only direct link with the mainland. Pop. (1961) 27,211. Area 35 sq.mi. (91 sq.km.). Sheppey is 10½ mi. in extreme length from east to west, and 5 mi. wide at its broadest point.

It is low lying with a small elevation near the north coast which presents slight cliffs toward the shallow sea. There are occasional incursions from the sea but protective measures have been taken to prevent further erosion and flooding. Except for the higher ground, the island is treeless but very fertile, producing grain and vegetables; its name, meaning the "island of sheep," is still appropriate. Leysdown and Minster are rapidly developing as holiday camping resorts. On the west are the ancient borough and port of Queenborough and the naval establishment of Sheerness (*qq.v.*).

SHEPSTONE, SIR THEOPHILUS (1817–1893), British South African statesman, was largely responsible for the peaceful development of Natal (*q.v.*). He was born at Westbury, near Bristol, Eng., on Jan. 8, 1817, the son of the Rev. William Shepstone, a Wesleyan minister. The family emigrated in 1820 to Cape Colony, where Shepstone was educated at his father's mission station. He acquired great proficiency in the Xhosa (Kaffir) languages and insight into Xhosa culture, both of which later helped to make him an outstanding administrator. He served as headquarters interpreter on the staff of the governor of Natal, Sir Benjamin D'Urban (*q.v.*), in the sixth Kaffir War (1834–35), and at the end of the campaign remained on the frontier as clerk to the agent for the native tribes. In 1838 he was one of the force sent to occupy Port Natal at Durban, and when the force was recalled in 1839, Shepstone was appointed British resident among the Fingo and other tribes in Kaffraria.

After Natal was placed under separate government in 1845, Shepstone was made agent for the native tribes. In 1848 he became captain general of the native levies, and in 1855 judicial assessor in native causes. When Natal became a colony, he was secretary for native affairs and a member of the executive and legislative councils from 1856 to 1877. The main line of his policy was to maintain tribal customs as far as was consistent with humane principles, and not to attempt to force civilization on the tribes. When the Zulu king Dingane was murdered in 1840 Shepstone resettled the tribal remnants scattered by the king's reign of terror on new locations under the successor king Panda (Mpande). So well was a tribal structure of sorts achieved that the only subsequent major risings in Natal were in 1873 and 1906. His policy was based on security of tribal tenure and the custom based on that tenure, both subject to his own authority as supreme chief. Also, apart from the crisis of 1873, he kept Natal tribes from being involved in frontier wars.

On two occasions he moved into Zululand (*q.v.*) on political errands. In 1861 he persuaded Panda formally to recognize his son Cetshwayo (*q.v.*) as successor, and in 1873 Shepstone attended the proclamation of Cetshwayo as king and made him swear to rule without illegal violence. During Shepstone's absence from Africa in 1879, Cetshwayo rejected an ultimatum to stop his forays over the border in pursuit of fugitives, was himself captured and exiled, but at his partial restoration in 1883, Shepstone was specially commissioned to install him. In 1874 Shepstone was consulted in London on native policy by the secretary of state for colonies, and in 1876 Sir Theophilus attended the conference there on South African affairs to discuss how to achieve a federal approach to native problems. He returned with a commission empowering him to confer with the Transvaal (*q.v.*) executive on the question of the federation of South African states and, should he deem it necessary, to annex the country, subject to the confirmation of the British government. He went to Pretoria in January 1877 with a force of 25 mounted policemen, and on April 12 issued a proclamation announcing the establishment of British authority over the Transvaal though he did not have majority approval of the *volksraad*. Outwitted and obstructed in the Transvaal and ill supported both by the Cape government and the Colonial Office, Shepstone remained in Pretoria as administrator until January 1879, when he was replaced and summoned home to London to advise the Colonial Office on South African affairs. On his return to Natal in 1880, he retired. During his retirement he was the victim of controversy, not the least was because he opposed the grant of responsible government to Natal out of fear that native policy would become a political football between two parties. He died in Pietermaritzburg on June 23, 1893.



RADIO TIMES HULTON PICTURE LIBRARY

SHEPSTONE

Shepstone was knighted in 1876, and the town of Port Shepstone, Natal, was named after him. The natives called him "father" and "Somsteu," in reference to his hunting abilities.

His younger brother JOHN WESLEY SHEPSTONE (1827–1916) was in the civil service in Natal, acting as secretary for native affairs and judicial assessor (1861, 1874, 1876–83).

Of Sir Theophilus' six sons, Theophilus (1843–1907) was advocate of the supreme court of Natal and a member of the legislative council; Arthur J. (1852–1912) served in various native expeditions, as assistant commissioner in Zululand (1887–89, 1889–90), in the South African War (1899–1902), and also as magistrate at various times from 1901 through 1907.

See C. J. Uys, *In the Era of Shepstone* (1933); E. H. Brookes, *The History of Native Policy in South Africa from 1830*, 2nd ed. (1927); D. R. Morris, *The Washing of the Spears* (1965). (W. A. ML.; X.)

SHER ALI KHAN (1825–1879), amir (king) of Afghanistan from 1863 to 1879, was born at Kabul in 1825. When his father, Dost Mohammed Khan (*q.v.*), died in 1863 he left behind him more than a dozen sons, of whom five aspired to the throne, though the amir had nominated Sher Ali, his third surviving son, as his heir. Sher Ali promptly proclaimed himself amir, but from the outset he was confronted by innumerable difficulties with his two elder brothers, Muhammad Azam and Muhammad Afdal, and with his nephew, Abd al-Rahman, son of Afdal. In 1866 Abd al-Rahman seized Kabul and in the next year drove Sher Ali from Kandahar. Afdal having died in 1867, Abd al-Rahman shifted his support to Azam, but Sher Ali and his eldest son Yakub defeated them in 1868.

In the early part of his reign Sher Ali was on excellent terms with the British, particularly with Lord Lawrence, the viceroy of India. In March 1869 he accepted an invitation from Lord Mayo, Lord Lawrence's successor, and met the new viceroy at Ambala. Sher Ali imprisoned Yakub when he rebelled at the naming of his younger brother, Abdullah Jan, as successor. Mayo refused to recognize him, thus arousing Sher Ali's resentment. Similarly British arbitration of a border dispute which gave a good part of the most fertile lands in Seistan to Persia in 1873 further alienated the amir. In the same year British failure to assure Sher Ali of support against Russian territorial advances turned the amir to Russia, who assured him they would not support Abd al-Rahman. In 1876 Lord Lytton succeeded Lord Northbrook as viceroy of India. An advocate of the "forward policy," Lytton moved British troops closer to Afghanistan and sought to have a British mission received by Sher Ali. The amir refused the request, in 1878 received a Russian mission, and turned back a British mission at the border. Abdullah Jan died. Thus the British government drifted into the Second Afghan War (1878–81). On Nov. 21, 1878, the three great passes leading into Afghanistan were entered by British armies, which took Kabul. Sher Ali, hoping to get help from the Russians, left Yakub Khan in Kabul

as regent and went to Mazar-i-Sharif, hoping to get help from the Russians. The Russians advised him to make his peace with the British. The amir, already worn out by physical disease and mental worry, died at Mazar on Feb. 21, 1879. *See* also AFGHANISTAN. (MD. A.)

SHERATON, THOMAS (1751–1806), English furniture designer, was born at Stockton-on-Tees, County Durham, the son of a working cabinetmaker. He appears to have been apprenticed to a cabinetmaker (an obituary notice in *The Gentleman's Magazine* [London, 1806] stated that Sheraton "worked for many years" at that trade), but he was ever a strange blend of mechanic, inventor, artist, mystic, and religious controversialist. Indeed, it is as a writer on theological subjects that we first hear of him. In 1782 he published at Stockton *A Scriptural Illustration of the Doctrine of Regeneration*, to which was added *A Letter on the Subject of Baptism*, describing himself on the title page as a "mechanic, one who never had the advantage of collegiate or academical education." He settled in London probably about 1790, and his trade card gave his address as Wardour Street, Soho, where he "teaches perspective, architecture and ornaments, makes designs for cabinetmakers, sells all kinds of drawing-books." Nothing is said of him as a maker of furniture, and all he tells us in his works is that "having possessed a strong attachment for carving in my youth, I was necessarily inclined to make attempts in this art . . . and was employed in the County occasionally in it."

Supporting himself "mainly by his exertions as an author" Sheraton published in four parts between 1791 and 1794 *The Cabinet-Maker and Upholsterer's Drawing Book*, by far his most important undertaking. The first part, which throws a curious sidelight on the author's mentality, is devoted to verbose dissertations on perspective, architecture, and geometry, which strike the reader as a naïve attempt to display the author's learning. But the notes on the plates are much fuller than in any other comparable publication and reveal sound technical knowledge. They leave no doubt that Sheraton's primary aim was "to exhibit the present taste in furniture"; as he put it himself, "I have made it my business to apply to the best workmen in different shops, to obtain their assistance in the explanation of such pieces as they have

(LEFT) "A NEW DESIGN OF A BOOKCASE & WRITING DRAWER" FROM THE CABINET-MAKER AND UPHOLSTERER'S DRAWING BOOK BY THOMAS SHERATON, 3RD ED., 1802. (RIGHT) 18TH-CENTURY SATINWOOD WORKTABLE MADE FROM A DESIGN IN THE SAME BOOK: IN A PRIVATE COLLECTION

been most acquainted with." In one or two instances he even informs the reader where specialized pieces of furniture may be obtained; a worktable is "taken from one executed by Mr. McLean in Marylebone Street . . . who finishes these small articles in the neatest manner." It is on the designs in the second part of the *Drawing Book* that Sheraton's reputation (in a great measure misleading) is certainly based. Throughout they are admirable in draftsmanship, rarely at fault in form or proportion, while the distribution and propriety of the ornament may be explained in part by the author's "strong attachment and inclination for carving."

In 1803 Sheraton brought out his *Cabinet Dictionary* (with plates), containing *an Explanation of all Terms Used in the Cabinet, Chair and Upholstery Branches With Dictionary for Varnishing, Polishing and Gilding*. It does not fulfill the promise of the title: the selection of terms is arbitrary and eclectic, suggesting that the author's marked tendency to eccentricity was on the increase. It is, however, sober and informative compared with Sheraton's final project, the *Cabinet-Maker, Upholsterer and General Artists' Encyclopaedia*, of which only one volume covering A to C appeared in 1805, the year before his death. The text warrants the inference that he suffered at least from mental instability, while the garish colour plates may be said almost to travesty the prevailing Regency style, so marked is the eccentricity of some of the designs.

Adam Black, a Scottish publisher and politician who was employed by Sheraton in connection with the encyclopaedia, refers to the latter's "painfully humble circumstances" and describes his house as "half shop, half dwelling-house"—firsthand evidence which should alone have sufficed to refute the legend that Sheraton was a fashionable cabinetmaker. Even now, however, pieces are often described as "by Sheraton" in catalogues and press reports of sales. There are several examples which are either virtually identical with, or closely resemble, a Sheraton design, but this affords no presumption that he was the maker. Sheraton's books, like those of the other great cabinetmakers of the second half of the 18th century, were intended not for the general reader, but for the practical use of the trade, which, no doubt, copied their designs extensively; indeed, hundreds of cabinetmakers and joiners were among the subscribers to the *Drawing Book*. It was in fact a trade catalogue, the plates of which were reproduced throughout the country with varying degrees of accuracy. It is reasonable to suppose that he himself obtained orders by the publication of his books and employed other cabinetmakers to manufacture the work; it seems certain that he himself never possessed anything more than a small shop. Of his own manufacture only one piece is known with certainty—a glass-fronted bookcase, stamped "T. S." inside one of the drawers.

Though Sheraton doubtless borrowed what served his turn, there is good reason to suppose that the bulk of the plates in his publications were engraved from his own designs. The version of the neoclassical style represented in Hepplewhite's *Guide*, which appeared only three years earlier than the *Drawing Book*, conveys a general impression distinctly different from that associated with Sheraton. The style in the earlier book, simple, elegant, and notably free from extravagance and eccentricity, as interpreted by Sheraton becomes more refined and feminine in character; the eccentricity so conspicuous in Sheraton's later works is as yet scarcely perceptible. The designs bear the mark of a single controlling intelligence, eclectic and even now and again ready to reproduce existing models, but gifted with an innate sense of proportion and style. Much of what he borrowed he adapted and improved upon. The term "Sheraton" has been recklessly bestowed upon vast quantities of late 18th-century painted and inlaid satinwood furniture, but properly understood and used in a generic sense it is an appropriate recognition of the most powerful source of inspiration behind the furniture of the century's closing years. Sheraton writes slightingly of Hepplewhite's *Guide* in his preface, and it is significant that in the 3rd edition of the *Guide* (1794) the designs for chairs are drastically amended, some of those with square backs then newly introduced being scarcely distinguishable from the chairs illustrated by Sheraton.

That Sheraton can have been personally popular is incredible. His books make it evident that his character was tart, angular, and self-assertive, and that he was little disposed to be generous toward the work of predecessors or rivals. Such an attitude toward the world would suffice to explain his lack of substantial success. He appears to have preached occasionally to the end, and even in his furniture books he sometimes falls into improving remarks of religious character. He died in Soho on Oct. 22, 1806.

See R. Edwards and M. Jourdain, *Georgian Cabinet-makers*, 3rd ed. (1955); R. Fastnedge, *Sheraton Furniture* (1962). (R. ED.)

SHERBORNE, a market town and urban district in the West Dorset parliamentary division of Dorset, Eng., 19 mi. (31 km.) NNW of Dorchester by road. Pop. (1961) 6,053. Area 2.6 sq.mi. It lies near the border of Somerset on the southern slope of a hill overlooking the River Yeo, in a fertile, well-wooded district. In 1951 traces of Romano-British occupation were found in the southern part of the town, dating from the 2nd–3rd century A.D. Other sites include a large Roman settlement, 10 ac. in extent, overlying occupation of the British (Belgic) period. It is first mentioned in 705 as the place where St. Aldhelm fixed his bishopstool for the new diocese of Western Wessex. In 1075 the see of Sherborne was transferred to Old Sarum and the cathedral of Sherborne became the abbey church of St. Mary the Virgin. Roger de Caen, bishop of Old Sarum from 1107 to 1139, replaced the Saxon church by a Norman building, parts of which remain today. Pre-Norman work appears in the western wall, and there are an Early English chapel and some Decorated windows. The church, however, was almost entirely reconstructed in the Perpendicular period; the colour decorations in the choir and the stone-vaulted roof with fan tracery being particularly fine. The completion of this work in 1490 gave existence to the Pack Monday Fair, which is still held annually on the first Monday after Oct. 10. Of the original building of the old castle, also built by Bishop Roger, only the gatehouse, portions of the curtain wall, the chapel, the keep, and certain domestic buildings remain. In 1139 the castle was seized by Stephen and remained with the crown until 1355, when it was returned to the bishops and retained by them until 1599, when it was given by Elizabeth I to Sir Walter Ralegh who built the present castle, now used as a museum. During the Great Rebellion the old castle was twice besieged, Cromwell himself being present in 1645 when it fell to Gen. Thomas Fairfax after a defense lasting 16 days. The almshouse of St. John Baptist and St. John the Evangelist was refounded in 1437 and retains a Perpendicular chapel, hall, and other portions. The town is an educational centre. Sherborne Boys' School now occupies the site of the school for which Edward VI granted a charter in 1550. There are also Sherborne Girls' School and Lord Digby's School for Girls, founded in 1743. Silk weaving was introduced by Huguenots in 1740 and the town also specializes in glove making and agriculture. It has a milk factory, light engineering and printing works, and a brewery.

SHERBROOKE, ROBERT LOWE, VISCOUNT (1811–1892), British statesman, leader of the opposition to the Reform Bills of 1866 and 1867, chancellor of the exchequer from 1868 to 1873, was born on Dec. 4, 1811, at Bingham, Nottinghamshire, the son of an Anglican minister. He was educated at Winchester and at University College, Oxford, where he distinguished himself by taking first place in classics and a second in mathematics, besides taking a leading part in the Union debates. He was fellow of Magdalen College (1835–36) until he married Georgiana Orred. Lowe became renowned as the outstanding tutor of his day, a savage examiner, and an energetic controversialist. Called to the bar in 1842, he emigrated in the same year to New South Wales, where he was soon prominent in the courts and in the Legislative Council as a supporter of efficient but representative government. Lowe made his mark in the political world by his clever speeches, particularly on finance and education, and besides obtaining a large legal practice, he was one of the principal writers for the *Atlas*, a weekly newspaper. In 1850 he returned to England in order to enter political life there, "with a tolerable fortune and a detestation of democracy," and became a familiar figure in society, his previous university reputation and connections, his colonial experience, and his caustic wit standing him in good stead. He began writing leaders (editorials) for *The Times* in 1851, and until J. T. Delane left the editorship in 1877 Lowe's influence remained considerable.

Lowe was Liberal member of Parliament for Kidderminster, Worcestershire (1852–59), and afterward represented Calne, Wiltshire (1859–68), and the University of London (1868–80). He was joint secretary of the Board of Control for India (December 1852–February 1855) under Lord Aberdeen, and vice-president of the Board of Trade (August 1855–March 1858) and vice-president of the Committee of Council for Education (June 1859–April 1864) under Lord Palmerston. In these minor offices he helped to establish competitive entry to the Indian civil service; his Joint-Stock Company Acts of 1856 and 1857 accepted the principle of limited liability; and he introduced the Revised Code (1862) of "payment by results" in elementary education (*see* EDUCATION, HISTORY OF), opposition to which caused his resignation in 1864. He rather scandalized his old university friends by the stress he laid on physical sciences as opposed to classical studies.

Lowe proved an effective speaker and a capable administrator; but his brusque manner and sarcastic contempt for both vested interests and eager reformers gave much offense. An albino, and almost blind, he ascribed his faults to "physical rather than moral deficiencies." However, there can be no doubt of his intellectual arrogance, confidently and lucidly expressed, nor of the rigour with which he applied his harshly Benthamite views, stressing the sole criteria of merit for the individual and of utility and economy for the actions of the state. Fortified by experience in both England and Australia, and on his visit to the United States in 1856, Lowe regarded democracy as the enemy of good government, which he considered should be based upon a limited, informed electorate. He was satisfied with Palmerston's benign conservatism, tempered by Gladstonian efficiency. In 1866, by a series of shrewd and brilliant speeches, he caused the defeat of Lord John Russell's Reform Bill and brought down the Liberal ministry. Few men have more completely (or unexpectedly) dominated the House of Commons.

As leader of the Adullamites (*q.v.*), the group of antireform Liberals, Lowe's influence attained its zenith; yet his very success stimulated the demand for parliamentary reform and thus inadvertently helped to produce Benjamin Disraeli's more drastic measure, the Second Reform Act (1867). Despite Lowe's mutiny of 1866, Gladstone made him chancellor of the exchequer in 1868, admiring his talents and trusting his opinions on finance; and Lowe gave the reforms of Gladstone's most notable administration his full support. Maintaining Gladstone's tradition at the Treasury, Lowe was at first a success; but after 1871 his old lack of tact became a liability. He was transferred to the Home Office in 1873, but his active political life came to an end with the ministry's defeat in the following year. When the Liberals returned to power in 1880, Lowe, already almost forgotten, was created Viscount Sherbrooke. His first wife having died in 1884, Lowe married Caroline Sneyd in 1885. He had no children by either marriage. He died at Sherbrooke Lodge, Warlingham, Surrey, on July 27, 1892, and the title became extinct.

See Asa Briggs, *Victorian People* (1954). (A. F. T.; X.)

SHERBROOKE, a city and seat of Sherbrooke County, Quebec, Can., is about 100 mi. (161 km.) E of Montreal and 30 mi. (48 km.) N of the U.S. boundary at Derby Line, Vt. It was named after Sir John Coape Sherbrooke (1764–1830) who from 1816 to 1818 was governor-general of Canada. Its situation at the confluence of the Magog and St. Francis rivers first brought it importance as a trading centre where the French bought furs from the Indians. Later, along with the surrounding regions (known as the Eastern Townships), it was further developed by United Empire Loyalists and their descendants as a water-powered grist mill centre for the grain from their agricultural holdings. It was incorporated as a town in 1852 and as a city in 1875. The population in 1966 was 74,229, more than 85% being of French origin. The intersection there of the principal east-west and north-south road and rail routes of the Eastern Townships, plus a large labour force and ready markets, have contributed toward the emergence of Sherbrooke as an important industrial, commercial, and cultural centre.

It is the seat of a Roman Catholic bishopric and of the Université de Sherbrooke, a French-language Roman Catholic university chartered in 1954. Hydroelectric power developed from neighbouring rivers helped in attracting over 100 industries to the city. The principal of these are engaged in the manufacture of textiles, transportation, quarrying, and mining equipment, machinery, oil burners, gloves, dairy products, leather and rubber goods, boots and shoes, hosiery and paper. A television station broadcasts mainly in the French language. Tourism and summer

cabin settlements are important in the surrounding hilly areas and lake districts and favour the city through increased trade and commerce in the summer months. (W. F. Ss.)

SHERIDAN, PHILIP HENRY (1831–1888), most successful Union cavalry leader of the American Civil War, was born March 6, 1831. Sheridan left his birthplace in doubt, at different times listing Albany, N.Y., Boston, Mass., and Somerset, O. No supporting evidence can be found for any one of the three. He entered West Point from his boyhood home of Somerset in 1848, and, while there, his habit of fighting cost him a suspension that delayed his graduation until 1853. Later this aggressive spirit, under better control, marked Sheridan as a military leader. Nine years of duty, mostly at frontier posts in the Southwest and the Northwest, brought him into the Civil War as a quartermaster officer in Southwest Missouri.

THE GRANGER COLLECTION
GENERAL SHERIDAN, PHOTOGRAPHED BY MATHEW BRADY

His desire to get into combat was satisfied in the spring of 1862 when he was appointed colonel of the 2nd Michigan Cavalry. On July 1 at Booneville, Miss., Sheridan skilfully split his outnumbered command to rout a large Confederate force, and Gen. W. S. Rosecrans declared that he was worth his weight in gold. He was made a brigadier general. At Perryville, Ky., (Oct. 8) he led the 11th Division, Army of the Ohio, as it held its position against repeated attacks. At the battle of Stones River (Dec. 31, 1862, to Jan. 3, 1863) he was made a major general of volunteers for his unyielding defense of the Union right centre. Later the Army's move south to drive the Confederates from Tennessee brought defeat to Rosecrans at Chickamauga, Ga. (Sept. 19–20). Though forced to withdraw, Sheridan managed to regroup his division but he was too late to aid Gen. G. H. Thomas, which exposed Sheridan to some criticism after the war. In the assault on Missionary Ridge below Chattanooga (Nov. 25, 1863), Sheridan brought his fighting in the west to a brilliant close, and Grant called him east in the spring of 1864 to head the cavalry of the Army of the Potomac.

Sheridan at once lifted the morale of the troops by re-outfitting the command, curtailing picket and escort duty to give the command more independence of action, and dismounting his men whenever possible to exploit the firepower of their new repeating weapons. Following action in the Wilderness (May 5–6), Sheridan led a raid toward Richmond that destroyed supplies and rolling stock, and resulted in the death of the South's great cavalry leader, "Jeb" Stuart.

On Aug. 4 Sheridan took command of the Army of the Shenandoah, charged with clearing that rich valley of Confederates and destroying their means of subsistence. A six-week delay for preparations taxed Northern patience, but in the battle of Opequon (Sept. 19) Sheridan drove Gen. Jubal Early out of Winchester. Further victories at Fisher's Hill (Sept. 22) and Cedar Creek (Oct. 19) quickly made him a major general. It was at Cedar Creek that Sheridan arrived after his famous ride from Winchester to stabilize his front and reverse what might have been a defeat. This battle also brought him the thanks of Congress. Meanwhile, on Grant's orders, Sheridan had destroyed the capacity of the Shenandoah Valley to support operations by the South. Near the end of March 1865 he rejoined his cavalry before Petersburg. With the 5th Corps Infantry added to his command, he circled south and west of the city to cut Lee's rail communications. On March 31 at Dinwiddie Court House and next day at Five Forks, Sheridan broke into the Confederate right and rear, forcing Lee to retire westward from his Richmond–Petersburg lines. But Sheridan, despite his success, felt that General Warren had lagged in pressing the attack of his 5th Corps and so removed him from command. The order brought Sheridan under considerable fire both at the time and later. To Grant, however, he remained the ideal officer, one who had shown that driving ahead at all cost was the only way to win the war. Sheridan continued his pressure against Lee's southern flank and at the end helped close off his escape near Appomattox. By now Sheridan's driving force had made him a dynamic and popular general. Soldiers responded enthusiastically to his banner-waving gallops along the lines. His reputation as a combat leader was secure.

The war over, Sheridan was ordered to the Gulf, where his presence along the Texas border hastened the fall of Maximilian, the French puppet emperor in Mexico. But later, as military commander of Louisiana and Texas in 1867, Sheridan's failure to adjust to the complex requirements of civilian authority led to his removal. He spent the next years until 1883 in western command. He planned and conducted a successful Indian campaign during the winter of 1868–69, after which he was promoted to the rank of lieutenant general. Abroad in 1870–71, Sheridan remained for two months as an observer at German headquarters near the close of the Franco-German War. Back at his Chicago headquarters, he married Irene Rucker, daughter of a fellow officer, in 1875. He became general in chief of the Army Nov. 1, 1883, and on June 1, 1888, received his commission as full general. He spent his last months writing his *Personal Memoirs* (2 vol., 1888), and died on Aug. 5 of that year in Nonquitt, Mass.

See Richard O'Connor, *Sheridan the Inevitable* (1953).

(E. J. N.; X.)

SHERIDAN, RICHARD BRINSLEY BUTLER (1751–1816), Irish-born dramatist remembered for his brilliant comedies of manners, but also important in his own period as a Whig politician, as adviser to the prince of Wales (later George IV), and as a political orator, was the third son of Thomas and Frances Sheridan. The date of his birth is not known, but he was baptized (mistakenly as "Thos. Brinsley") at St. Mary's Church, Dublin, on Nov. 4, 1751. His family later moved to London, and he never returned to Ireland. He was educated (1762–*c.* 1767–68) at Harrow, and in 1770 moved with his family to Bath.

While there he corresponded with Nathaniel Halhed, a schoolfriend then at Oxford. Together they wrote *Jupiter*, a farce, which after revision, Sheridan renamed *Ixion*. They also collaborated in a metrical version (1771) of the epistles of Aristaenetus. Sheridan's poems "The Ridotto of Bath" and "Clio's Protest" also date from this period.

In Bath, Sheridan met Elizabeth Ann Linley (1754–92), whose fine soprano voice had, from an early age, delighted audiences at the concerts and festivals conducted by her father, Thomas Linley (*q.v.*). She thought herself persecuted by a Welsh squire, Thomas Mathews of Llandaff, and decided to take refuge in a French nunnery. In March 1772, Sheridan accompanied her to Lille, but returned to fight duels with Mathews, in London on May 4 and at Bath on July 1, 1772. Meanwhile, Elizabeth had returned home with her father, and Sheridan was ordered by his father to Waltham Abbey, Essex, to pursue his studies. He was entered at the Middle Temple on April 6, 1773, but broke with his father and a legal career on April 13, when he married Elizabeth at Marylebone Church, London.

Dramatic Career.—After his marriage, Sheridan turned to the theatre for a livelihood, and his comedy, *The Rivals*, was produced at Covent Garden Theatre on Jan. 17, 1775. It ran for an hour longer than was usual; and, because of the offensive nature of the character of Sir Lucius O'Trigger, and also because this part was poorly acted, it was hardly a success. Drastically revised for its second performance on Jan. 28, and with a new actor as Sir Lucius, it won immediate applause. The situations and characters were not entirely new, but Sheridan gave them freshness by the buoyancy of his wit and his richly humorous presentation. The scenes between Sir Anthony Absolute and his son are particularly striking, and the whole play reveals Sheridan's remarkable sense of theatrical effect. Characteristic too, is the genial mockery of affectation: the absurdities of Lydia Languish and Acres are unforgettable. Even the "malapropisms" that slow down the play give a

proper sense of caricature to the character of Mrs. Malaprop.

Some of the play's success was due to Lawrence Clinch's acting as Sir Lucius. Sheridan showed his gratitude by writing for Clinch's benefit night (May 2, 1775) the amusing little farce, *St. Patrick's Day: or, The Scheming Lieutenant*. Another example of his ability to invent an interesting plot from well-worn materials is *The Duenna* (Covent Garden, Nov. 21, 1775). The characters, except for the delightful Isaac Mendoza, are undeveloped, but the clever intrigue and charming lyrics, and the music by Thomas Linley and his son, gave this ballad opera great popularity. Its 75 performances even exceeded the record number of 62 credited to Gay's *The Beggar's Opera* (1728), and it is still revived.

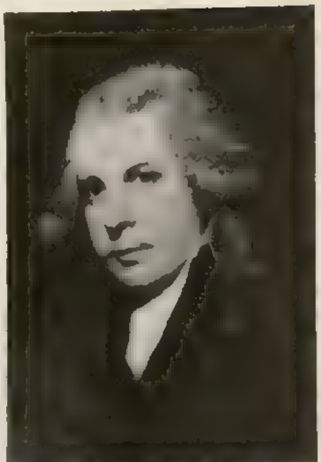
Thus, in less than a year, Sheridan had brought himself to the forefront of contemporary dramatists. David Garrick (*q.v.*), looking for someone to succeed him as manager and proprietor of Drury Lane Theatre, saw in him a young man with energy, shrewdness, and a real sense of theatre. A successful physician, Dr. James Ford, agreed with this estimate and decided to increase the amount of money he had thought of investing in the playhouse. In 1776, Sheridan and Linley became partners with Ford in a half-share of Drury Lane Theatre, and they bought the other half from Willoughby Lacy, Garrick's partner, two years later. Sheridan had only £1,300 in the concern, and the transaction was only possible because Garrick and Ford backed him with mortgages in the belief that Drury Lane would flourish under his direction.

In fact, Sheridan's interest in his theatre soon began to seem rather fitful, but he was responsible for the renewed appreciation of Restoration comedy that followed the revival at Drury Lane of the plays of William Congreve (*q.v.*). In February 1777, he also brought out his version of Vanbrugh's *The Relapse* (1696) as *A Trip to Scarborough*. This again showed his talent in revision. He gave the rambling plot a neater shape, and removed much indelicacy from the dialogue, but the result was disappointing, probably because the play had lost much of its gusto.

What Sheridan learned from the Restoration dramatists can be seen in *The School for Scandal* (Drury Lane, May 8, 1777), which earned him the title of "the modern Congreve." Although resembling Congreve in that its satirical wit is so brilliant and so general that it does not always distinguish character, it contains two subtle portraits in Joseph Surface and Lady Teazle. There were several Restoration models (*e.g.*, Mrs. Pinchwife in Wycherley's *The Country Wife*, and Miss Hoyden in Vanbrugh's *The Relapse*) for the portrayal of a country girl, amazed and delighted by the sexual freedom of high society, but Sheridan softened his Lady Teazle to suit the more refined taste of his day. The part combined innocence and sophistication and was incomparably acted by Frances Abington (*q.v.*). The other parts were written with equal care to suit the members of his company, and the whole work is a triumph of intelligence and imaginative calculation. Further, its spirited ridicule of affectation and pretentiousness makes it the best comedy of manners in English.

The auction and screen scenes in *The School for Scandal* demonstrate Sheridan's flair for stage effect, shown again in his delightful satire on stage conventions, *The Critic*, which, ever since its first performance (Oct. 30, 1779), has been thought much funnier than its model, *The Rehearsal* (1671) by the 2nd duke of Buckingham (*q.v.*). Sheridan himself considered the first act his finest piece of writing. Its character sketches are cleverly drawn and, although Puff is little more than a type, Sir Fretful Plagiary is not only a caricature of the dramatist Richard Cumberland (*q.v.*), but an epitome of the vanity of authors in every age.

Political Career.—Sheridan continued to adapt plays and to improvise spectacular shows at Drury Lane, but, as a succession of acting managers took over the burden of direction, his time was increasingly given to politics, and his only full-length later play was the worthless but popular patriotic melodrama, *Pizarro* (Drury Lane, May 24, 1799), based on August von Kotzebue's *Die Spanier in Peru* (1796). Sheridan had become member of Parliament for Stafford in September 1780, and was under-secretary for foreign affairs in Rockingham's ministry (1782) and secretary to the treasury in the duke of Portland's coalition ministry (1783). He



BY COURTESY OF THE LORD PLUNKET

RICHARD BRINSLEY SHERIDAN, DETAIL OF A FULL-LENGTH PORTRAIT BY SIR JOSHUA REYNOLDS, 1788–89

took office again, in the "ministry of all talents" (1806), as treasurer of the navy (1806–07), and became a privy councilor. The rest of his 32 years in Parliament were spent in opposition. His critical acumen and command over language had full scope in oratory, and were seen at their best in his speeches as manager of the impeachment of Warren Hastings (*q.v.*). Although recognized as one of the most persuasive orators of his time, however, he never acquired the political influence he and others thought he deserved, because he was regarded as an unreliable intriguer. There is some support for this view in his behaviour during the Regency crisis (1788–89), when he acted as the prince of Wales' adviser, and in the party squabbles (1791–93) with Edmund Burke (*q.v.*).

He was one of the few members courageous enough openly to defend those who suffered for their support of the French Revolution. Indeed, Sheridan liked taking an individual stand, and although he supported Charles James Fox (*q.v.*), he came out on the side of government when he condemned the Nore mutineers (1797). Much to Fox's disgust, he also gave Addington's administration (1801–04) some support.

In November 1806, Sheridan succeeded Fox as member for Westminster (although not, as he had hoped, as leader of the Whigs), but he lost the seat in May 1807. The prince of Wales then returned him as member for the pocket borough of Ilchester, but his dependence on the prince's favour rankled with Sheridan, because they differed in their attitude to Catholic emancipation. Sheridan, who was determined to support emancipation, stood for Stafford again in 1812, but could not pay those who had previously supported him as much as they expected, and as a result was defeated.

Last Years.—His financial difficulties were largely brought about by his own extravagance and procrastination, as well as by the destruction by fire in February 1809 of Drury Lane Theatre (which had been rebuilt in 1791–94). When he lost his parliamentary seat, and his income from the theatre, he became a prey to his many creditors. His last years were unhappy because of these difficulties, and because of worry over his circulatory complaints, and the cancer that afflicted his second wife, Hester Jane Ogle, daughter of the dean of Winchester. He had married her in April 1795, three years after Elizabeth's death. Sheridan himself died in London on July 7, 1816, pestered by bailiffs to the end. Even in decline, he made a strong impression on Byron, who wrote a *Monody on the Death of the Right Honourable Richard Brinsley Sheridan* (1816), to be spoken at Drury Lane Theatre.

Conclusion.—Sheridan's genius both as dramatist and politician lay in humorous criticism, and ability to size up situations and relate them effectively. These gifts were often exercised in the House of Commons on other men's speeches, and at Drury Lane in the revision of other men's plays. They are seen at their best in *The School for Scandal*, where he shaped, from two mediocre draft-plays of his own, a plot and dialogue of unusual brilliance. In person he was often drunken, moody, and indiscreet, but he possessed great charm and powers of persuasion. As a wit he delivered his sallies against the follies of society with a polish that makes him the natural link between Congreve and Wilde.

THOMAS SHERIDAN (1687–1738), grandfather of the dramatist, was born at Cavan, Ire., in 1687. He is chiefly known as a companion and confidant of Jonathan Swift, whom he offended by fulfilling an old promise to tell Swift if he ever saw signs of avarice in him. He died in poverty at Rathfarnham, Ire., Oct. 10, 1738.

THOMAS SHERIDAN (1719–1788), son of the above, was noted for his *Pronouncing Dictionary* and for his advocacy of a scheme of public education, in which elocution was to play an important part. He was born in Dublin in 1719 and died at Margate on Aug. 14, 1788.

FRANCES SHERIDAN (1724–1766), wife of the above and mother of the dramatist, gained some fame as a playwright. She died on Sept. 26, 1766, at Blois.

BIBLIOGRAPHY.—*Editions and Bibliography: The Plays and Poems of R. B. Sheridan*, ed. by R. Crompton Rhodes, 3 vol. (1928) is the standard text. It should be supplemented by R. L. Purdy's excellent edition of *The Rivals, a Comedy, as it was first Acted at the Theatre Royal in Covent Garden* (1935), and by G. H. Nettleton's texts of *The Rivals, The School for Scandal*, and *The Critic*, in *British Dramatists from Dryden to Sheridan*, ed. by Nettleton and A. E. Case (1939). No full bibliography of Sheridan's works has been published: valuable bibliographical material is to be found in J. P. Anderson's lists in L. C. Sanders' *Life of R. B. Sheridan* (1890); in *The Major Dramas of R. B. Sheridan*, ed. by G. H. Nettleton (1906); in the works by Sichel (*see* below) and Rhodes (*see* above); and in I. A. Williams, *Seven XVIIIth-Century Bibliographies* (1924). On bibliographical points *see* also F. W. Bateson, "Notes on the Text of Two Sheridan Plays," in *Review of English Studies*, vol. xvi (1940); G. W. Williams, "A New Source of Evidence for Sheridan's Authorship of *The Camp* and *The Wonders of Derbyshire*," in *Studies in Philology*, vol. xlvii (1950); W. van Lennep, "The Chetwynd Manuscript of *The School for Scandal*," in *Theatre Notebook*, vol. vi (1951); C. Price, "Hymen and Hirco: a Vision," in the *Times Literary Supplement* (July 11, 1958), and "The Text of the First Performance of *The Duenna*," in *Papers of the Bibliographical Society of America*, vol. liii (1959).

Biography and Criticism: Thomas Moore's *Memoirs of . . . Sheridan*, 5th ed., 2 vol. (1827) is indispensable. William Smyth's *Memoir of Mr. Sheridan* (1840) is a brief but vivid account from personal acquaintance. W. Fraser Rae, *Sheridan*, 2 vol. (1896) and W. Sichel, *Sheridan*, 2 vol. (1909) are full accounts, printing much new material, but are not altogether reliable. R. C. Rhodes, *Harlequin Sheridan* (1933), provides a scholarly review of evidence about disputed passages in Sheridan's life. L. Gibbs, *Sheridan* (1947), gives a useful summary of accepted material. J. Dulck, *Les Comédies de R. B. Sheridan* (1962), is a close examination of Sheridan's achievement from the French point of view. (C. J. L. P.)

SHERIFF (HIGH SHERIFF), a senior executive officer in an English county or smaller area, who performs a variety of ancient administrative and judicial duties. Officers of this name also exist in Scotland, Northern Ireland, and the United States.

England.—The office of sheriff is of pre-Conquest origin. In the 10th century the Anglo-Saxon shire was controlled by the ealdorman, who presided in its court jointly with the bishop and the king's reeve, the sheriff. By the 11th century the ealdorman had become responsible for a whole province rather than a single shire; and the separation of the ecclesiastical from the secular courts under William I left the sheriff supreme in the county and as president of its court. He convened and led the military forces of the shire, executed all writs, and for the first century after the Conquest judged both criminal and civil cases. But the increasing use, from the time of Henry II, of itinerant justices from the *curia regis* ("king's court") and the reservation to the *curia* and its developing branches of all serious criminal and some civil cases, severely restricted his jurisdiction. Henceforth his duty was to investigate allegations of crime from within his shire, to conduct a preliminary examination of the accused, try lesser offenses, and detain those accused of major crimes for the judge's assize. Twice a year he made his "tourn" in the hundred (*q.v.*) courts. He was also responsible for all dues owed to the Exchequer, to which the sheriff alone had audience and direct obligation for his shire. In the later part of the 12th century this duty was also limited by the supervisory powers of itinerant justices and eventually he ceased to attend the Exchequer.

In the late 11th and the 12th centuries the sheriffs wielded great power. There was always danger of the office becoming hereditary. In 1170 Henry II held an inquest on the conduct of his sheriffs and many were dismissed. A statute of 1300 ordering sheriffs to be elected by the county was superseded in 1315 by one arranging for their appointment by various officers of state. In 1340 the office became annual only. The new offices of coroner (first mentioned in 1194), of local constable (first mentioned in 1242), and of justice of the peace (first known, in the 12th century, as *custodes pacis*, "keepers of the peace") all took work and duties from the sheriffs. The office was not included in the Tudor reorganization of local government, and since that time has been largely ceremonial. English law was consolidated in the Sheriffs Act, 1877; local variations disappeared in a unified set of duties. The sheriff attends on the judges at assizes and election petitions and is responsible for the execution of writs; he prepares the panel of jurors for assizes, is liable for the safe custody of prisoners, and acts as returning officer at parliamentary elections. Until the Murder (Abolition of Death Penalty) Act, 1965, he was responsible for the execution of sentences of death. The sheriff still holds his county court for a few limited purposes, but this court is quite distinct from the modern County Courts established by statute in 1934. His administrative duties have been reduced also by his subordinacy in the county to the Lord Lieutenant, the principal executive officer. Sheriffs are usually nominated by government for the counties, and by corporations for cities and towns which formerly gained the right by royal charter to have sheriffs of their own.

Scotland.—The sheriff, as a ministerial and judicial officer, appears in records from the 12th century, and, despite the later introduction of the office of justice of the peace, the sheriff has retained considerable and greater powers. Sheriffs and sheriff substitutes for the 15 sheriffdoms are appointed and removed by the crown on recommendation or order of the secretary of state for Scotland. Grounds for removal are personal unfitness. A sheriff must be an advocate or sheriff substitute of five years' standing; a sheriff substitute, who is a judicial officer salaried by the crown, must be an advocate or solicitor of similar standing. The appointment, tenure of office, and judicial duties of the sheriff and substitute are fixed by the Sheriff Courts (Scotland) Acts, 1876, 1907, and 1913. The original jurisdiction of the Sheriff Court is largely exercised by sheriff substitutes, and in certain civil matters appeal lies to the sheriff, and through him to the Court of Session. The civil jurisdiction of the Sheriff Court extends to nearly all actions, and the Small Debt Court is also presided over by the sheriff or sheriff substitute. Only grave crimes are excepted from the criminal jurisdiction of the Sheriff Court, these being tried by the High Court. Honorary sheriff substitutes are appointees of sheriffs; the sheriff of Chancery is appointed by the Crown.

Northern Ireland.—The sheriff and salaried under-sheriff for a county are appointed by the governor, and their duties, similar to those in England, are set out in the Sheriffs (Ireland) Act, 1920.

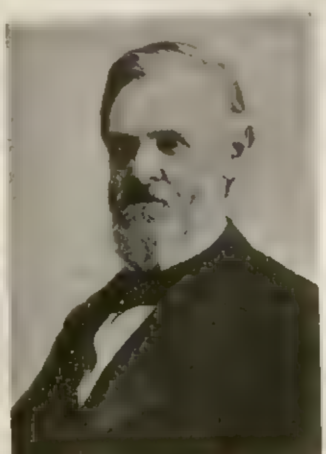
United States.—The sheriff ordinarily is an elected public officer in his county, the chief executive officer and an officer of the court, with a term usually from two to four years. The deputy is appointed by the sheriff and is delegated duties. The sheriff and deputy are peace officers, and thus have the power of police officers in the enforcement of the criminal law. They may assume the functions of the local police department, but carry personal responsibility. The city marshal plays a similar role in his city or municipality, but is generally regarded as chief of police. As a means of preserving public order the sheriff is empowered to call out the *posse comitatus* (*q.v.*). The sheriff's judicial duties principally concern the service and return of process, and the execution of writs, particularly judgments by sale or distress. Though usually a salaried official, he is sometimes paid from fees, which, in populous counties, can be lucrative.

See W. S. Holdsworth, *A History of English Law*, vol. 1, 7th ed. (1956); P. W. Wager (ed.), *County Government Across the Nation* (1950). (D. W. M. W.)

SHERIFFMUIR, a battlefield near the western end of the Ochil Hills, in the parish of Dunblane, Perth County, Scot., and 2½ mi. (4 km.) E by N of the town. It was the site of a drawn battle (Nov. 13, 1715) between the Jacobites, about 12,000 strong, under John Erskine, earl of Mar, and 4,000 Hanoverians, under John Campbell, 2nd duke of Argyll. About 500 men were lost on each side. Both armies claimed the victory, but Mar felt it prudent to withdraw, and the encounter, occurring one day before the defeat of the Jacobites at Preston in England, was fatal to the Jacobite cause. The "Gathering Stone of the Clans," upon which

the Jacobites are supposed to have sharpened their dirks before the battle, can still be seen. (G. S. P.)

SHERMAN, JOHN (1823–1900), U.S. statesman, financial administrator, and author of major legislation concerning the currency and regulation of commerce. He was born at Lancaster, O., on May 10, 1823, a younger brother of William Tecumseh Sherman (*q.v.*), who was to win fame as a general in the American Civil War. The son of a judge of the state supreme court, he studied law with an uncle and a brother at Mansfield, O., and was admitted to the bar in 1844. Law was his major concern for ten years, although he also took an interest in politics and was a delegate to two Whig national conventions. After the repeal of the Missouri Compromise by the Kansas-Nebraska Act of 1854, he joined the Anti-Nebraska movement against the extension of slavery and was elected to Congress in the autumn. He won early distinction in the House of Representatives by drafting the majority report of a committee sent to investigate troubles in Kansas in 1856 (*see* KANSAS: *History*). In 1859 he was the Republican choice for the speakership but fell short of a majority in the badly divided House. Elected to the Senate in 1861, he served in that body until 1897, except for the years 1877–81 when he was President Hayes's secretary of the treasury.



THE GRANGER COLLECTION

SHERMAN

In both House and Senate his major interest was in financial legislation, and after 1867 he was chairman of the Senate finance committee. He was associated with the enactment of important war and postwar fiscal measures. For a time he favoured payment of government bonds in Civil War greenback currency, a concession to western inflationist sentiment, but in 1875 he was largely responsible for the Specie Resumption Act that provided for redeeming them in coin at face value. In 1879, as secretary of the treasury, he carried out the policy successfully. He opposed free coinage of silver, but accepted the limited coinage authorized by the Bland-Allison Act of 1878.

During the Harrison administration the Anti-Trust Act of 1890 and the Silver Purchase Act of the same year bore his name, but both represented compromises which had only his qualified approval. (*See* UNITED STATES [OF AMERICA]: *History*.)

Sherman's name was presented to three Republican national conventions—1880, 1884, and 1888—but the presidential nomination eluded him. His middle-of-the-road course on monetary policies suited neither the inflationist West nor the conservative East; his sober, colourless personality attracted no devoted following; and his candidacy lacked whole-hearted support in his state.

During the last years of his senatorial career he was chairman of the Senate committee on foreign affairs. Upon the accession of President McKinley he accepted the position of secretary of state, thus creating a senatorial vacancy for Marcus A. Hanna, McKinley's campaign manager. Difficulties with Spain over Cuba made his new duties too exacting for his strength, and in April 1898 he resigned. He died at Washington, D.C., on Oct. 22, 1900.

Kerr, *John Sherman, His Life and Public Services* (2 vol., 1908); *John Sherman's Recollection of Forty Years in the House, Senate and Cabinet*, 2 vol. (1895); Rachel Sherman Thorndike, ed., *The Sherman Letters* (correspondence between John Sherman and William Tecumseh Sherman from 1837 to 1891; 1894). (E. H. Ro.)

SHERMAN, ROGER (1721–1793), American political leader of the Revolutionary era and signer of the Declaration of Independence. He was born at Newton, Mass., April 19, 1721, and grew up in Stoughton, Mass. In 1743 he moved to New Milford, Conn., where he combined shoemaking with farming and studying until he was appointed to the lucrative post of county surveyor. After being admitted to the bar in 1754 he practised law, engaged in trade, and wrote an almanac. Moving to New Haven, Conn., in 1761, Sherman established a general store and took an active part in the affairs of his church, town, and colony. He was treasurer of Yale College, 1765–76; a member of the governor's council, 1766–85; and mayor of New Haven from 1784 to 1793. Though Sherman's stand on questions ranging from paper money to religion was consistently conservative, during the dispute with England he was among the first to realize the impossibility of reconciling the British and American points of view.

As a delegate to the Continental Congress, Sherman signed the Non-Importation Articles of Association in 1774 and the Declaration of Independence in 1776. He helped draft the Articles of Confederation and approved the peace treaty with England. Perhaps his greatest service was performed during the Constitutional Convention of 1787 when he helped to bring about a compromise (often called the Connecticut Compromise) between the large and small states and thus prevented a deadlock. (*See* CONSTITUTIONAL CONVENTION [U.S.].) In Congress under the new Constitution, first as a representative (1789–91) and then as a senator (1791–93), he supported Alexander Hamilton's program for assuming state debts, establishing a national bank, and enacting a protective tariff. Sherman's rugged homespun qualities served as a symbol of patriotic dedication and puritan simplicity to his own and later generations. He died in New Haven on July 23, 1793.

SHERMAN, WILLIAM TECUMSEH (1820–1891), one of the ablest Union generals in the American Civil War, leader of the famous march through Georgia in 1864, was born on Feb. 8, 1820, at Lancaster, O. When his father, a judge of the supreme court of Ohio, died in 1829, leaving a widow with a family of 11 children, Thomas Ewing, a prominent Ohio politician and close friend of the father, took William into his home. When the boy came of age he entered West Point and graduated near the head of his class in 1840. His first field service was in Florida against the Seminole Indians. Thereafter, amid the usual changes of station and detached duty, he studied law. When the war with Mexico began in 1846 he asked for field duty and was sent to join an expedition going to California by sea. He became executive officer in the administration of local government until California became a part of the United States in 1848. In 1850 he married Ellen Ewing, daughter of his adoptive father, who was then serving as the first secretary of the interior in the president's cabinet.

Three years later Sherman resigned from the army and, attracted by the possibilities he had observed in California, went to San Francisco to manage a branch of a St. Louis bank. The panic of 1857 interrupted a promising career in business. He then engaged in business in New York for a brief time and practised law in Leavenworth, Kan., before becoming superintendent of a newly established Louisiana military academy, which opened its doors on Jan 1, 1860. When the southern states seceded Sherman resigned his post and returned to St. Louis. His devotion to the Union was strong but he was greatly distressed at what he considered an unnecessary conflict between the states.

He offered his services to the U.S. army and on May 4, 1861 was appointed colonel of a new infantry regiment. He was soon assigned to command a brigade in Brig. Gen. Irvin McDowell's army and served with it in the disastrous first battle of Bull Run. Promoted to the rank of brigadier general of volunteers, he was ordered to Kentucky to serve as second-in-command to Gen. Robert Anderson, who had commanded Fort Sumter when the first shots of the war were fired. In October Sherman succeeded to the command of the department of the Cumberland but soon lost it when he reported to his superiors that he needed 200,000 men for the Kentucky campaign. At this point in his career his eccentric behaviour and suspicion of news reporters led some newspapers to describe him as insane. He was nevertheless placed at the head of a division of new recruits and accompanied Grant's army to Pittsburg Landing. At the nearby battle of

Shiloh his raw troops received the first shock of the Confederate assault. His conduct won him promotion to the rank of major general.

Sherman took part in the succeeding attack on Corinth, Miss. At the close of 1862 he led the Mississippi column in the first Vicksburg campaign. Though he suffered defeat at Chickasaw Bluffs, his capture of Fort Hindman, near Arkansas Post, served to restore his reputation. In Grant's final Vicksburg campaign Sherman commanded the right of the line.

After the capture of Vicksburg on July 4, 1863, Sherman was sent to oppose Gen. *Joseph E. Johnston* near Jackson, Miss. (For convenience in identification, Confederate leaders are italicized.) His star, along with Grant's, was now in the ascendant. Their careers would thereafter be closely linked as they worked together to bring about the end of the conflict. When Grant was placed in supreme command of the west, Sherman succeeded to the command of the Army of the Tennessee and in that capacity he took part with Grant in the battle of Chattanooga in November. In March 1864, when Grant became general-in-chief of the Union armies, Sherman was made commander of the military division of the Mississippi, including the Army of the Tennessee, then under Gen. J. B. McPherson, the Army of the Cumberland under Gen. G. H. Thomas, and the Army of the Ohio under Gen. J. M. Schofield. After detaching some troops for garrisons and minor operations in a theatre of war over 500 mi. wide, he assembled near Chattanooga his three armies, aggregating 100,000 men, and began in May the invasion of Georgia. *Johnston* retreated slowly and strategically ahead of him. Outside Atlanta, *Johnston* was replaced by *Hood*, who gave battle but was forced back into the city and compelled on Sept. 1 to evacuate and leave the field to Sherman. The war was not going well in the east and this much-needed victory restored northern morale and helped ensure the reelection of Lincoln in November.

CULVER PICTURES, INC

SHERMAN

Hood in early October began a vigorous movement designed to carry the war back into Tennessee. He moved across Alabama to northern Mississippi but Sherman refused to be diverted. Union superiority in manpower was beginning to tell. Sherman could leave Thomas and Schofield behind to deal with *Hood* while he went ahead with his celebrated "March to the Sea" from Atlanta to Savannah with 60,000 men. This was total war with a vengeance. Cutting loose from his supply base, he set out for Savannah, living off the country, destroying railroads and supplies, reducing the war-making potential of the Confederacy and bringing the war home to the people themselves.

He reached Savannah in time for Christmas. In Jan. 1865, once more abandoning his base, Sherman marched northward toward Virginia where Grant and *Lee* were approaching a final showdown. *Johnston*, recalled to raise an army to stop him, could not muster a sufficient force, and Sherman was in Raleigh, the capital of North Carolina, by April 13. During this march Columbia, the capital of South Carolina, had burned. Though Sherman denied responsibility for it, Carolinians charged him with it. His army had destroyed much property, had burned some homes and had done considerable plundering along the way, making their commander the symbol to southerners of the ruthless invader. The war was now drawing to a close. Thomas and Schofield had utterly destroyed *Hood's* army and Schofield had joined Sherman in North Carolina. *Lee's* position in Virginia was increasingly desperate, and Sherman with 90,000 men was steadily pushing *Johnston* ahead of him as he moved toward *Lee* from the south. A few days after *Lee* surrendered *Johnston* also gave up the struggle. Sherman gave him even more generous terms of surrender than Grant had given *Lee* but was compelled to recall those parts dealing with the political settlement to follow the end of the conflict.

Sherman remained a soldier to the end, though his view of warfare was succinctly put in his oft-quoted assertion that "War is hell." A century later, in the nuclear age, it is tragically amusing to read that Sherman believed that another war could not last four years because the new weapons of destruction, such as semiautomatic rifles and quick-firing artillery, would leave nobody to fight that long. Unlike Grant, Sherman refused to become involved in politics, saying he would not run if nominated and would not serve if elected. At the end of the war he went first to St. Louis and continued his interest in the growing west by working with the army to pacify Indians and build the transcontinental railroad. When Grant became a full general in 1866 Sherman moved up to the rank of lieutenant general. When Grant became president in 1869 he made his old comrade-in-arms commanding general of the army, a post he held until Nov. 1883. One of his lasting achievements was the establishment of a centre for military training at Fort Leavenworth, Kan.

Early in the year 1884 Sherman retired from active duty, living for a time in St. Louis and then in New York city. He lived until Feb. 14, 1891, a well-known and popular, if sometimes controversial, figure to the end. He published two volumes of memoirs in 1875.

See AMERICAN CIVIL WAR; *see* also references under "Sherman, William Tecumseh" in the Index.

(C. W. TE.)

SHERRINGTON, SIR CHARLES SCOTT (1857–1952), English neurologist noted for his studies of reflex action, in 1932 received (with E. D. Adrian, *q.v.*) the Nobel Prize for Medicine for discoveries regarding the function of neurons. He was born in London on Nov. 27, 1857. He was educated at Gonville and Caius College, Cambridge, receiving his B.A. (1883) with a first-class honours in natural science; and at St. Thomas Hospital Medical School, London, (M.B., Cambridge, 1885). After conducting research on epidemic cholera in Spain and Italy, he was a fellow of Caius College and lecturer at St. Thomas Hospital (1887–93). In 1891 Sherrington became Brown professor of Pathology, London, and superintendent of the Brown Animal Sanatory Institution; in 1895 Holt professor of physiology, Liverpool; and was Waynflete professor of physiology, Oxford, 1913–35, retiring in 1936. He also held the Fullerian chair of physiology at the Royal Institution, 1914–17. Made a fellow of the Royal Society in 1893, he served as president, 1920–25. He was knighted in 1922.

While at Caius College, he investigated the anatomy of nerve paths between the brain and the spinal cord. Later he turned to the physiology of the spinal cord after isolation from the brain and proved the presence of sense organs in skeletal muscles, thus ending the ancient controversy about "muscle sense." Next, he showed how complex was spinal reflex action in the scratch reflex. He suggested that the lability of reflex nerve centres came from physicochemical states in the points of contact between nerve cells, which points of adjunction he called synapses. His Silliman lectures at Yale in 1904, published as *The Integrative Action of the Nervous System* (1906; reprinted 1947), became a standard work and established his worldwide reputation, marking out new fields for physiological research. (*See* REFLEX: *Development of Reflex Theory*; FEELING, PSYCHOLOGY OF: *Theory of Feeling: Sense Organs Involved.*)

Sir Charles died at Eastbourne, Sussex, on March 4, 1952.

(E. G. T. L.; X.)

's HERTOGENBOSCH, capital of North Brabant Province, Neth., lies at the confluence of the Dommel and Aa rivers, which unite to form the Dieze, and 29 mi. (47 km.) SSE of Utrecht. Pop. (1960) 71,597. Founded by Henry I, duke of Brabant, the town was granted city rights in 1185 and remained an important fortress until 1874. St. John's Cathedral, with a well-preserved

interior, is one of the finest in the country, and the Baroque town hall has a carillon of 30 bells. Opposite the town hall stands the statue of the painter Hieronymus Bosch (*q.v.*), who was born there. The covered cattle market (1933) is the largest in Western Europe. An international vocalist competition and a summer course for vocalists are held annually. The town is a rail and road junction, with links to all parts of the Netherlands and to Belgium and Germany.

SHERWOOD, ROBERT EMMET (1896–1955). U.S. author whose plays reflect the gradual shift of the intellectual position of his generation—from irresponsible detachment to responsible involvement in human problems. He was born in New Rochelle, N.Y., April 4, 1896. He was an indifferent student at Milton Academy and Harvard, failing the freshman rhetoric course while performing well and happily on the *Lampoon*, the humour magazine, and Hasty Pudding, the college musical comedy show. He left before graduation to enlist in 1917 in the Canadian Black Watch Battalion, served in France, was gassed, and was discharged in 1919. He was drama editor of *Vanity Fair* (1919–20) and with his colleagues there, Dorothy Parker and Robert Benchley, found his way to the Algonquin Round Table, the centre of a New York literary coterie that included Harold Ross, Alexander Woollcott, Heywood Broun, Franklin P. Adams, Frank Sullivan, Marc Connelly, George S. Kaufman, and Donald Ogden Stewart. Sherwood was associate editor (1920–24) and editor (1924–28) of the humour magazine *Life*. His first play, the urbanely witty historical *The Road to Rome* (1927), criticizes war as pointless. The heroes of *The Petrified Forest* (1935) and *Idiot's Delight* (Pulitzer Prize, 1936) begin as detached cynics but realize their own bankruptcy and sacrifice themselves for their fellowmen. In *Abe Lincoln in Illinois* (Pulitzer Prize, 1939) and *There Shall Be No Night* (Pulitzer Prize, 1941), in which his pacifist heroes decide to fight, Sherwood shows that only by losing his life for other men can a man make his own life significant. In 1938 Sherwood formed with Maxwell Anderson, Sidney Howard, Elmer Rice, and S. N. Behrman the Playwrights' Company, which became a major producing company.

© KARSH, OTTAWA
SHERWOOD

The Lincoln play led to Sherwood's introduction to Eleanor Roosevelt and ultimately to Pres. Franklin Delano Roosevelt, for whom he served as speechwriter and adviser. Sherwood's speechwriting did much to make ghostwriting for public figures an accepted practice. Between service as special assistant to the secretary of war (1940) and secretary of the Navy (1945), Sherwood served as director of the overseas branch of the Office of War Information (1941–44). From his wartime association with Roosevelt came much of the material for *Roosevelt and Hopkins: an Intimate History*, for which he received his fourth Pulitzer Prize in 1949. Except for his Academy-award-winning film *The Best Years of Our Lives* (1946), Sherwood's theatrical work after World War II was negligible. He married Mary Brandon in 1922, and, after divorcing her in 1934, married Madeline Hurlock in 1935. Sherwood died in New York, Nov. 14, 1955.

See John Mason Brown, *The Worlds of Robert E. Sherwood* (1965). (Js. T. N.; X.)

SHERWOOD FOREST, one of the ancient English forests, in Nottinghamshire. It extended from Nottingham northward to Worksop, being over 20 mi. (32 km.) long by 5 to 9 mi. (8 to 14 km.) broad. Though subject to forest law, it is not mentioned in Domesday Book because it was not liable for tax. Sherwood, a crown forest from the time of Henry I, is traditionally noted as the retreat of the outlaw Robin Hood. It once contained vast numbers of deer. Today about 12,500 ac. (5,059 ha.) are under national ownership, administered by the Forestry Commission as productive plantations, mostly of pines; many veteran oaks remain and there is some birch and beech, and much bracken. The forest is on the Bunter sandstone and much of the ground is too poor for agriculture, but in the 18th century great parks, with extensive woodlands, were laid out to form the "Dukeries." Deep-lying coal seams have been extensively developed and colliery settlements built. Mansfield (*q.v.*) is the main town. (H. L. En.)

SHESHONK (SHISHAK, SHOSHENQ), pharaoh of Egypt, in the 22nd dynasty, from *c.* 945 to 924 B.C. In the Old Testament he is called Shishak. He came from a line of princes or sheikhs of Libyan tribal descent, whose title was "great chief of the Meshwesh" and who appear to have settled in Heracleopolis, in middle Egypt, though Manetho says the family came from Bubastis in the eastern delta. Sheshonk appears to have ascended the throne without a struggle, and he married his son Osorkon to a daughter of Psusennes II, the last king of the foregoing dynasty.

The Bubastite portal at Karnak (*see* THEBES) bears a relief and inscriptions celebrating this king's victories in Palestine. This was the occasion (*c.* 930 B.C.) when "Shishak king of Egypt came up against Jerusalem" (I Kings 14:25–26) in support of Jeroboam, the pretender, who challenged the right of Solomon's son Rehoboam to succeed to the Israelite throne. The biblical account speaks of the looting of the palace and Temple, though the name Jerusalem has not survived in the Egyptian record. A fragment bearing Sheshonk's name has, however, been found at Megiddo.

There were three other pharaohs of the same name later in the dynasty. *See* also EGYPT: *History*. (M. S. Dr.)

SHETLAND, or ZETLAND, as it is spelled officially, is a group of about 100 islands, islets, and skerries (fewer than 20 of them inhabited) lying about 130 mi. (209 km.) to the north of the Scottish mainland, constituting the most northerly county of Scotland. The main island, Mainland, is much the largest, being, though narrow, about 50 mi. (80 km.) long. The total area of land in the county is 550.5 sq.mi. (1,426 sq.km.). Lerwick, the county town, lies about a third of the way up Mainland on the east side.

Physical Features.—The scenery of Shetland is wild and in places very fine. Its most distinct characteristics are perhaps the voes or sea lochs which indent all the coasts, often enclosed by steep hills and giving from the higher ground fine views over sea and coast. Though subject to fierce storms in fine weather (especially in summer when the light lasts all night) sea and land take on intense and sometimes rather unearthly colourings. There are few trees. The winds are so continuous and strong that even vegetables require shelter. As the main form of agriculture is crofting, each croft having a few acres of arable land and the right to keep so many sheep on the *scattald* or common grazings, the lower ground bears the typical aspect of crofting districts. The croft houses are usually low cottages and the arable ground lies around them giving way up the hillsides to rock and heather. There are streams and some freshwater lochs but no rivers.

The common seal is abundant in the Shetland waters, especially between Lerwick and the north isles. Brilliant red and purple sea urchins occur along the shores, due to the presence of the Atlantic drift.

The geological character of the islands resembles that of northern Scotland. Old Red Sandstone, red grits, sandstones, and marls and conglomerate occur in a narrow belt on the east side of Mainland. The remainder of the island is occupied by metamorphic schists and gneisses with which are associated dikes and masses of intrusive igneous rock.

Mainland is almost cut in half just north of Brae. The northern portion, Northmaven, is sparsely inhabited. It contains Ronas Hill, the highest point in the islands (1,475 ft. [450 m.]). The western parishes, stretching out to Walls and Sandness, are also thinly populated. Tingwall, the site of the ancient "Ting" or Norse parliament, lying directly north of Lerwick, is the most fertile part of the island and contains one or two sizable farms. South of Lerwick in Dunrossness there is some good land, and the districts are more thickly populated.

To the north of Mainland are Yell, the next in size, and Unst, the most northerly and populous of the islands. Offshore and 1 mi. NW of the entrance to Burra Firth is Muckle Flugga Lighthouse, the most northerly point of the British Isles. Ponies are bred on Fetlar, northeast of Mainland, and Whalsay, lying farther south, is inhabited by fishermen.

Off the western seaboard are six inhabited islands (including Muckle Roe, now joined to Mainland by a bridge). Among these Papa Stour has fine caves. Foula lies in the Atlantic, 16 mi. (26 km.) from the west mainland and is rocky and exposed. Fair Isle, 20 mi. (32 km.) S of Sumburgh Head, the southernmost point of Mainland, belongs to the National Trust for Scotland and has two lighthouses, and an ornithological observatory under the Fair Isle Trust. Noss has been a nature reserve since 1955.

History.—Zetland or Shetland is a modernized version of the old Norse name *Hjaltland*. The original inhabitants were probably a primitive people who lived in rough, sunken dwellings. Various stone circles survive as well as brochs (circular stone towers) of Pictish origin. In the 7th or 8th century the islanders began to be converted to Christianity by missionaries of the Celtic Church from Ireland or the west of Scotland, although the work was not completed until later. In the 8th and 9th centuries the islands were invaded by the Norsemen who ruled them until the 15th century. The Norsemen left a heavy imprint on the people and the local place-names, most of which are Norse in origin. The language, Norn, survived down to the 18th century, and various sea birds and parts of boats are generally known by their Norse names. In 1469 the islands, like Orkney in 1468, were given as a pledge for the dowry of Margaret, princess of Denmark, who married (1469) James III of Scotland. The pledge was never redeemed, and both groups were annexed to the Scottish crown in 1472. Large tracts of land were granted to Scottish nobles, and from the 16th century began a steady influx of Scots which, since many of them came as oppressive lairds, was by no means always popular with the native Shetlanders. For several centuries the islands have been famous for wool and knitwear, and fish. The origins of the "Fair Isle" patterns are disputed. They are probably native, although it has been suggested that they came from the crew of a Spanish Armada galleon which was wrecked on the Fair Isle. Development of herring fishing, which at one time supported stations in almost every voe and packed Bressay Sound and Baltasound with ships, was largely due to the Dutch in the 18th century; but the Shetlanders have always been great seamen. Many local customs, mostly of Norse origin, survive, such as Up Helly A', the winter festival (*see* LERWICK). The islands, however, on the whole have stood outside the mainstream of Scottish history; the kilt has never been a native dress nor Gaelic a native language. In fact, they have no share in the Celtic traditions of the Highlands. There are many dwellings and burial places dating from Pictish or Norse days, particularly Jarlshof at Sumburgh and the broch on Mousa. Shetland is the scene of *The Pirate* by Sir Walter Scott.

Stimulated by a Viking conference attended by representatives of the major Norse countries and held at Lerwick in 1955, archaeological investigations were begun in the south of the island. In 1957 considerable remains of a Celtic church were discovered. This church is believed to be one of a chain of such churches associated with St. Ninian and, in fact, to have been the mother church of the island.

Some months later a remarkable treasure of bronze ornaments was discovered beneath this church including 12 bronze brooches, six bowls, and a hanging lamp, as well as two unusual carved objects which may also have been used as brooches. These objects are believed to have been placed near the "founder's tomb" of the church. They form a particularly fine and well-preserved collection of Celtic work decorated with semiprecious stones.

Population and Administration.—The total population of the county was 17,812 in 1961, a decrease of 1,540 since 1951. There were 269 people on Bressay (335 in 1951), 127 (161) on Fetlar, 1,148 (1,101) on Unst, 764 (859) on Whalsay, and 1,155 (1,483) on Yell.

Lerwick (*q.v.*), a small burgh, is the capital and main port. Pop. (1961) 5,908 (5,538 in 1951). The only other town is Scalloway, the ancient capital, which lies almost opposite Lerwick on the west coast. It is a considerable fishing centre. It has the ruins of a castle built by Patrick Stewart, one of the most notorious of the Scottish landlords.

Shetland unites with Orkney to return a member to parliament. The island is divided into six districts. It forms a sheriffdom with Orkney and Caithness, and there is a resident sheriff-substitute at Lerwick. The system of udal tenure is still in existence on the islands.

Agriculture and Industries.—The soil of Shetland, except in certain districts, is poor and the climate inimical to many kinds of agriculture. The system of land tenure is mostly crofting and

J. ALLAN CASH FROM RAPHO GUILLUMETTE

(Above) Seagulls following fishing boats at Scalloway, Shetland (Right) Shetland ponies on the island of Unst. (Left) Eroded cliffs at Eshaness, Shetland. (Below) Typical small farm on Weisdale voe, Shetland

the main source of the crofters' income is wool. The Shetland breed of sheep produces a light fleece of very fine wool which is knitted by the crofters' wives and daughters into gloves, pullovers, socks, berets, etc., in the patterns known as "Shetland" or "Fair Isle." Many of the crofts do not yield a sufficient income for a family, however, and Shetland men often seek supplementary means of livelihood, usually at sea by fishing or in the navy, merchant service, or Antarctic whaling expeditions. Efforts were made to break out more land from the hill and increase the number of cattle, the native breed of which gives fair supplies of milk and, though light, the beef is of good quality. However, Aberdeen Angus and crossbred cattle have to some extent taken their place. Shetland ponies which once did all the work on the crofts are found in considerable numbers, especially on Unst. But demand for both croft and farm work and for the mines has much diminished, and the main market is now for childrens' ponies.

Lerwick is an important herring port; boats arrive there from the east coast of Scotland and England to join the local boats for the summer fishing. At Scalloway, too, much herring is landed early in the season. There is a fish-meal plant on Bressay and a quick-freezing factory at Lerwick, as well as curing facilities. Most of the herring stations in the countryside and the outlying islands have, however, been closed. and the number of boats fishing from Lerwick has decreased. All the year round white fish of all kinds, principally haddock and whiting, are caught by seine nets. The main fishing centres are Whalsay, Burra Isle, Lerwick, and Scalloway. For lack of adequate piers at Whalsay and Burra Isle most of the boats land at Lerwick or Scalloway. White fishing is also carried on elsewhere, notably from Out Skerries, Cullivoe, and Voe. Many crofters keep small boats from which they catch some haddock, whiting, or piltock for their own use. Fishing boats of other nations frequently call at Shetland harbours, the Norwegian dogfish and shark boats being a common sight. For many years the Swedes voyaged every summer to Baltasound to fish ling, but this decreased. Whales are occasionally seen around the Shetland coast, but whaling locally has ceased and the caaing whale is no longer driven ashore as it once was for food and lamp oil.

Apart from agriculture, wool, knitting, and fishing, the main native source of livelihood is a small amount of weaving. The stone in Unst is also quarried for talc. From time to time, efforts were made to start the working of peat and iron ore, but without success. Unemployment in the 20th century has been high.

Communications.—The north isles and Whalsay can be reached by regular ferry services and by steamer from Lerwick. The remainder of the islands are served by mail boats. There is an airport at Sumburgh from which there are daily services to Orkney, Inverness, and Aberdeen, and there are regular sailings between Lerwick and Orkney and Aberdeen.

SHEVKET, MAHMUD (MAHMUD SHEVKET PASHA) (1858–1913), grand vizier of Ottoman Turkey in 1913, was born in Baghdad in 1858, the son of a junior administrator (*mutisarrif*). After attending a primary school in Baghdad he went to the Cadet School in Constantinople and graduated as a staff captain in 1882. He then served on the general staff of the Ministry of War and was posted to Crete for a short time before returning to Constantinople to teach at the Cadet School. In 1886 he joined the commission which was sent to Germany to supervise the manufacture of war materials for Turkey. On his return he was appointed director of the Inspection and Control Department, with the rank of general.

After the Young Turk Revolution of 1908 Mahmud Shevket became commander of the 3rd Army which marched on Istanbul to suppress the counterrevolution of April 13, 1909. He supervised the suppression of the uprising and forced Sultan Abdul-Hamid II to abdicate. He then became inspector of the 1st, 2nd, and 3rd armies and minister of war. On Jan. 23, 1913, during the first Balkan War, some members of the Committee of Union and Progress marched on the Sublime Porte, killing the war minister, Nazim Pasha, and forcing Kiamil Pasha to resign. Mahmud Shevket Pasha was then made grand vizier. He preferred soldiering to politics but served his country well as grand vizier during his tenure of office. He was assassinated in Istanbul on June 11, 1913. He wrote several books on mathematics and military science, and a history of the Ottoman Army. *See* also TURKEY: *History*. (M. P. P.)

SHEWBREAD, in the Old Testament, an archaic English form of SHOWBREAD, to indicate that it is bread on display; also known as BREAD OF THE PRESENCE, for it is presented and shown in the Temple, in the presence of God.

The bread consisted of 12 loaves, arranged on a table in two rows of 6 each (Lev. 24:5 f.). This arrangement of the loaves was an important aspect of the presentation; I Chron. 9:32 and 23:29, and Neh. 10:33 literally speak of "the bread of the arrangement." The table, which stood at the west end of the "holy place" of the Temple, next to the Holy of Holies, was also important. In Ex. 25:23–30 is a description of its construction, and it is called "the table of the bread of the Presence" (Num. 4:7). The bread was changed every sabbath and the priests ate that which had been on display; though in emergency it was given to David and his men (I Sam. 21:6).

The 12 loaves stood for the 12 tribes of Israel. They were a symbolic acknowledgment that God was the resource for Israel's life and nourishment; at the same time they served as Israel's act of thanksgiving to God for this. Many aspects of the Christian Eucharist show influence of Israel's showbread. (J. C. RY.)

SHIBARGHAN, a town and capital of the minor province of Shibarghan in northern Afghanistan, lies 80 mi. (129 km.) W of Mazar-i-Sharif. Pop. (1962 est.) 50,264. It was formerly the capital of a small independent Uzbek khanate, which was allotted to the Afghans by the Anglo-Russian boundary agreement of 1873. It has a citadel but is not otherwise fortified, and is surrounded by gardens. It is on the main road from Kabul to Herat via Mazar-i-Sharif.

SHIBARGHAN PROVINCE (pop. 1962 est. 395,560) stretches northward over the desert plains of Afghan Turkistan to the Amu Darya (Oxus) and the Soviet frontier, and is bounded east by Mazar-i-Sharif and west by Maimana. In the south and southwest it extends to the provinces of Herat and Kabul and includes part of the northern foothills of the Band-i-Turkistan range. The province is drained by the Ab-i-Safed River and its chief crops are cotton, maize (corn), and melons. Carpet weaving, sheep grazing, and the preparation of karakul lambskins are the main occupations; the province produces the highest quality karakul. Oil has been found at Sar-i-Pul (south) and around Aq Chah (north). (J. P. C. N. H.)

SHIDEHARA KIJŪRŌ, BARON (1872–1951), Japanese diplomat and statesman who opposed the growth of militarism in his country, was born in Osaka on Aug. 11, 1872. A graduate of the Law College of the Tokyo Imperial University in 1895, he entered government service, serving briefly in the Agriculture and Commerce Department. Then he entered the diplomatic service serving as consul at Chemulpo, a Korean Japanese treaty port (1899), at London (1899), Antwerp, and other cities. He was secretary at the Head Office in 1911, Counsellor to the embassy at Washington (1912) and at London (1914), and minister to the Netherlands (1914–15). In 1915 he was vice-foreign minister and ambassador to the United States in 1919. In that capacity he argued in vain against U.S. immigration laws that discriminated against the Japanese. He was created a baron in 1920 and was a member of the House of Peers in 1925. As the chief Japanese delegate to the Washington Conference (1921–22) he accepted agreements favouring China, and as Japan's foreign minister from 1924 to 1927, and again from 1929 to 1931 he became known as an advocate of conciliation toward China and of peaceful policies generally. Forced from office by the militarists in 1931, he did not again play a significant role until October 1945 when, at the age of 73, he was accepted by the military occupation authorities as prime minister during the demilitarization period (until May 1946). He was then elected as a conservative to the lower house of the Diet where he served as speaker until his death on March 10, 1951. The

paradox of his liberalism abroad and conservatism at home may in part be explained by his long association with Mitsubishi financial interests. His wife, Iwasaki Masako, was the daughter of the founder of that *zaibatsu* combine. His book *Gaikō Gojūnen* (1951) describes his public career. (F. H. Co.; X.)

SHIEL, LOCH, a glacially excavated ribbon lake in the northwest Highlands of Scotland draining to a bay on the southern shore of Loch Moidart (a sea-loch) by the 31-mi.-long (50 km.) River Shiel. The loch is 17 mi. (27 km.) long, from 200 yd. to 1 mi. (1.6 km.) wide, and only 11½ ft. (3.5 m.) above sea level, with a maximum depth of 420 ft. (128 m.) (mean depth 81½ ft [24.8 m.]). The loch acts as a boundary between Moidart in Inverness and Sunart and Ardgour in Argyll. The lower 5 mi. (8 km.) runs east-west among gentle hills rising to about 600 ft. (183 m.); but Glen Finnan and the upper loch run fairly straight northeast-southwest among fine-conical glaciated hills rising to about 3,000 ft. The area around the head of the loch and the mouth of Glen Finnan has roads running east to Loch Eil and Fort William and west to Loch Ailort, Morar, Mallaig, and thence to Skye. A monument commemorates the raising of Prince Charles Edward's standard in 1745. On St. Finnan's isle are an ancient chapel and the traditional burial place of the Macdonalds. (A. T. A. L.)

SHIFNAL, a market town (formerly known as Idsall) of Shropshire, Eng., lies 17 mi. (27 km.) ESE of Shrewsbury by road. Pop. (1961) 3,896. The 12th-century church of St. Andrew is cruciform, combining examples of every period from late Norman to late Perpendicular. The town was destroyed by fire in 1591 and now consists chiefly of half-timbered and brick houses of the 17th and 18th centuries. Bishop Thomas Percy (*q.v.*) reputedly found the manuscript upon which he based his *Reliques of Ancient Poetry* (1765) in an old house in the marketplace. Trade is mainly agricultural, with some engineering. There are fat and store stock sales every Monday, but the November fairs have been discontinued. (M. C. Hl.)

SHIGA, prefecture (*ken*) northeast of Kyōto in South Honshu, Japan. Area 1,551 sq.mi. (4,017 sq.km.). Pop. (1965) 853,370. Biwa-ko (*q.v.*), the largest lake in Japan, and the surrounding mountainous district form Biwa-ko recreational park and occupy about 25% of the total area of Shiga. The percentage of paddy fields is the highest in Japan. Ōmi cows are famous as beef cattle. The textile industry at Ōtsu (*q.v.*), Hikone, and Nagahama owes its development in part to the chemical qualities of the lake water. Ōtsu, the prefectural capital, is also an important tourist centre. The tomb of Bashō (1644–94), greatest *haiku* poet, is at Shiga. From Ōtsu boats provide tours to the scenic "Eight Views" and other points on Biwa-ko. (R. B. H.)

SHIGA NAOYA (1883–), one of the deans of modern Japanese fiction, whose writings have served as model and inspiration for many younger authors, was born on Feb. 20, 1883, at the village of Ishinomaki in Miyagi prefecture but in 1885 was taken by his parents to Tokyo to live in his grandfather's home. From about 1899 he was drawn to Christianity, but later abandoned it, apparently because he could not accept such doctrines as that of original sin. Literature and art next claimed his allegiance. In 1906 he graduated from the Peers' School and entered the Department of English Literature at Tokyo Imperial University, leaving after two years. As a young writer Shiga developed an objective style, perceptively delineating the most sensitive reactions of his somewhat delicate characters. Spurts of literary activity, which earned him a reputation as a fine short-story writer, were separated by long periods of inactivity and he was unable to rely on writing for his living. In 1910 he joined Mushanokōji Saneatsu and other friends of his Peers' School days in founding the journal *Shirakaba* ("White Birch"), which emphasized individualism and Tolstoyan humanitarianism.

Much of Shiga's fiction is concerned with difficult family relationships, the result no doubt of his own problems with his family, especially with his father. Both the novelette *Wakai* ("Reconciliation"; 1917) and the long novel *An'ya kōro* or *Road Through the Dark Night* (written between 1925 and 1937) describe the hero's search for peace of mind in the face of family involvements. In *Wakai,* the first-person hero distresses his father by marrying the family maid. In *An'ya kōro,* the hero is the son of his apparent father's father; when he marries, his wife in turn contracts a liaison with a cousin, from which a child is born. Shiga's concern with the psychological involvements of his first-person heroes places some of his stories in the category of *shi-shōsetsu* ("I" fiction, private fiction).

Synopses of Shiga's work, with a biographical note, are found in *Introduction to Contemporary Japanese Literature,* part ii (1936–55) compiled by the Kokusai Bunka Shinkōkai (1959); English translations of his short stories are included in *Modern Japanese Literature,* ed. by Donald Keene (1957), *Modern Japanese Stories,* ed. by Ivan Morris (1962), and *The Heart Is Alone,* ed. by Richard N. McKinnon (1957). (J. K. Y.)

SHIH HUANG TI (259–210 B.C.), "First Sovereign Emperor," is the title assumed in 221 B.C. by King Cheng of the Chinese state of Ch'in (in northwest China) when he completed Ch'in's conquest of the other independent states into which China was then divided, thereby creating the first unified Chinese empire. It is from the state and empire of Ch'in that the name China probably derived.

The first emperor was born in 259 B.C., allegedly the natural son of a rich merchant and Ch'in statesman, Lü Pu-wei, though this story is possibly a slanderous invention. He ruled as king of Ch'in from 246 to 221 and thereafter as first emperor of all China until his death in 210. Major innovations instituted in and after 221 included: (1) abolition of the formerly independent Chinese states with their landed aristocracy and replacement of them by an administrative system of 36 (later 42) *chün* or provinces, subdivided into lesser *hsien* or prefectures and all governed by centrally appointed, nonhereditary, salaried officials; (2) simplification and standardization of the Chinese script according to the written characters current in Ch'in; (3) extension of the Ch'in system of laws, weights, and measures throughout the empire; (4) completion of the Great Wall as a barrier between China and its nomadic neighbours to the north and northwest; and (5) the "burning of the books," a governmental proscription of literature ordered in 213 to suppress Confucianism and other dissident schools of thought in favour of Legalism and to make the Ch'in version of past history the accepted one. These innovations, though formally ordered by the first emperor, were largely inspired by his prime minister, Li Ssŭ (*q.v.*).

The first emperor was a mighty conqueror, Machiavellian schemer, bold innovator, and at the same time a superstitious megalomaniac whose fear of death caused him to be searching for the Taoist elixir of immortality when he died in 210. His harsh reign was followed within a year by rebellion, leading to the collapse of the Ch'in dynasty and its replacement by that of Han (206 B.C.–A.D. 220). Though the Confucian historians reviled him as a ruthless tyrant, the first emperor's reign was crucially important for bringing China's feudal age to an end and inaugurating norms of empire that persisted until the founding of the Chinese republic in 1912. *See* also CHINA: *History.*

(D. Be.)

SHIHKIACHWANG (SHIH-CHIA-CHUANG, SHIH-MEN), an industrial, rail junction-terminal city in west Hopeh Province, China. Pop. (1958 est.) 623,000. In the 1920s it was only a small village near the old city of Chenting close to the Peking-Hankow railway. It lay at the junction of a branch line built to T'ai-yüan, Shansi, in the 1900s. The village became a terminal point and grew into a city of 217,000 by 1935. A rail link built to Te-chou, Shantung, during World War II increased Shihkiachwang's importance. The Chinese Communists, by the 1960s, had developed the city into a modern regional industrial, transport, and trade centre, with an airport, rail yards, cotton mills, and many new agricultural processing plants. (J. E. Sr.)

SHI'ISM, one of the two major branches of the religion of Islam (*q.v.*) distinguished from the majority Sunnism. One of the factions which disputed power over the early Muslim community and its vast conquests supported the claims of 'Ali (*q.v.*),

who was nominated fourth caliph, and then of his descendants. From a political faction (Shi'at 'Ali, "Party of 'Ali") this gradually developed into a religious movement, Shi'ism, which deeply influenced all Sunni Islam and also produced a number of important sects to which, especially, the term Shi'a is applied. In the mid-20th century, perhaps one-tenth of all Muslims were Shi'ites; *i.e.*, about 40,000,000. Shi'ism is the majority faith in the Iranian plateau and Iraq and perhaps Yemen, and is found in Syria, Lebanon, east Arabia, northern India (especially around Lucknow), in the Deccan and Bombay, Pakistan, and elsewhere.

'Ali was a first cousin and son-in-law of Mohammed, father of Mohammed's two grandsons, Hasan and Husain, by the Prophet's daughter Fatima. 'Ali was noted for his devoted piety and his valour in war. Raised to the caliphate (*q.v.*; 656) with the support of the murderers of the third caliph (another son-in-law of Mohammed), he never received the allegiance of all the Muslims but had to wage increasingly unsuccessful civil wars. When he was murdered (661), his chief opponent, Mu'awiya, was generally acknowledged caliph; for some time 'Ali was officially cursed from the pulpits of Islam. But many Muslims, especially at Kufa in Iraq, 'Ali's headquarters, hoped for an 'Alid restoration. On Mu'awiya's death they invited Husain, 'Ali's son, to become caliph. But they failed to support him at the crisis and he and his little band were cut down (680) near Kufa at Karbala, now a pilgrimage spot. (*See* HASAN AND HUSAIN.) The Kufans thereupon bewailed penitently the death of Mohammed's grandson and swore vengeance against the triumphant Islamic government. Repeatedly they supported insurrections by members of 'Ali's family, but without success.

The 'Alid cause soon gained support from other groups which opposed the *status quo*—for instance, from the aristocratic Muslim families of Medina, who eventually established a tradition of 'Alid rule in the holy cities; from pious men protesting against a too worldly interpretation of Islam; and from non-Arab Muslims, especially in Iraq, who demanded an equality refused them by the ruling Arabs. The 'Alids never won power (though it was initial Shi'ite help which set up the Abbasid dynasty [750], descended from another cousin of Mohammed). Yet 'Ali was rehabilitated as a major hero of Sunni Islam, and his descendants by Fatima have received a privileged status as *sayyids* and *sharifs*.

But the Shi'ites were not satisfied with this. Some, called Zaidis (Zaydis), whose principles were worked out in the 9th century, demanded, sword in hand, that the ruler must be whichever descendant of Hasan or Husain proved qualified, at a given time, by his knowledge and his practical ability; otherwise, they differed little from the Sunnis. They set up several small states along the Caspian and in Yemen. Other Shi'ites, called Imamis, asserted a more exalted religious role for the 'Alid claimants. They insisted that, in power or not, a given descendant of 'Ali was the divinely appointed imam, and sole authority in his time on all matters of faith and law. The more speculative among them, called Ghulat ("extremists"), sometimes paid the imams practically divine honours. The more moderate came in time to claim at least that a supernatural "Mohammedan light," embodied in them, gave them superhuman knowledge and power, and that their sufferings were means of divine grace to their devotees. Love of the imams and of their persecuted cause became equally obligatory with belief in God's oneness and in Mohammed's mission. Every year during the month Muharram, when Husain was killed, the Shi'ites mourned his death (sometimes with bloody self-lacerations) and condemned the guilty Sunnis. Under bigoted Sunni rule, they felt they might have to protect themselves from persecution by dissimulating their faith (*taqiyya*); but in the end the imam, as mahdi, the "well-guided," would deliver the faithful and punish their enemies. (*See* IMAM; MAHDI.)

Several sects acknowledged as imams the line of Mohammed ibn al-Hanafiyya, a son of 'Ali (not by Fatima), but these died out in the 9th century. Most Shi'ite sects have acknowledged one of two lines stemming from Husain's great-grandson Ja'far al-Sadiq (d. *c.* 765). One is that of the Isma'ilis, who developed a unique religious system and for a time established a powerful Fatimid caliphate, and are represented by the modern Khojas and Bohras, merchant communities of India and east Africa; from them split the Druze of Syria. (*See* DRUZE; ISMA'ILISM.)

The majority of modern Shi'ites acknowledge a younger line down to a 12th imam, Mohammed al-Muntazar, supposed to have gone into hiding in 878 and expected to return as mahdi before the Last Judgment to establish justice in the earth. Among these are the Nusairis (Nusayris) or 'Alawites of northern Syria, with a secret faith of complex origin; the 'Ali-Ilahis or Ahl-e Haqq, scattered peasants and herdsmen of Kurdistan, Turkey, and Iran; and the order of Bektashi dervishes in Turkey and Albania. But most who acknowledge the 12 imams belong to the Ithna 'Ashariya or "Twelver" sect (in Syria and Lebanon, Mutawali).

Despite occasional Shi'ite rulers, the Shi'a remained almost everywhere a minority faith till at the start of the 16th century the Persian Safavid dynasty made it the sole legal faith of their empire, embracing the Turks of Azerbaijan, the Persians of Iran, and the Arabs of Iraq proper; these have since been all overwhelmingly Twelver Shi'ites and have given that sect a vigorous modern life. Usulis, claiming the primacy of legal principle, have debated with Akhbaris, attached to established texts; with the speculative Shaykhis; and especially with the Babis and Baha'is of the 19th century. At the Shi'ite pilgrimage places, especially Najaf near Kufa in Iraq, scholars qualified to make independent judicial decisions, mujtahids, regarded as representatives of the hidden 12th imam, expound Islamic law according to the school of Ja'far, which differs in some particulars from each of the Sunni schools. They also have a political role as popular authorities, especially in Iran.

(M. G. S. H.)

SHIKOKU, the smallest of the four main islands of Japan, is separated from Honshu Island by the Inland Sea. Area 6,857 sq.mi. Pop. (1960; Kagawa, Ehime, Tokushima, and Kōchi prefectures) 4,121,423. Most of the population is concentrated in urban areas along the coast, and Takamatsu in the northeast is the major city. *See* JAPAN: *Geographic Regions*.

SHILLONG, the capital of Assam, India, and the headquarters of the United Khasi and Jaintia Hills District, is situated on the Shillong Plateau, about 60 mi. (97 km.) S of Gauhati, at an altitude of 4,987 ft. (1,520 m.) above sea level. Pop. (1961 Town Group, including the cantonment) 102,398. Shillong first came into prominence in 1864 when it was made headquarters of the Khasi and Jaintia Hills District in place of Cherrapunji. Ten years later it became the seat of government of the newly formed province of Assam. In 1954 the administrative headquarters of the North East Frontier Agency were established at Shillong. The town contains, besides the military cantonment, the Pasteur Institute and Research Laboratory, a dairy farm, five colleges connected with Gauhati University, and two large hospitals. Barapani hydroelectric power station, one of the largest in Assam, lies about 12 mi. (19 km.) N of the town. Shillong experiences frequent earth tremors and was devastated by the great earthquake of June 12, 1897. (M. BA.)

SHILLUK, a Nilotic nation, numbering 120,000 in the 1960s, settled along the west bank of the Nile, between Lake No and latitude 12° N in the south of the Republic of the Sudan (*q.v.*). They are sedentary negroid agriculturalists with strong pastoral interests (30,000 cattle, many sheep and goats). After long contacts with northern Sudan, and incorporation into the Ottoman Empire, they were under Anglo-Egyptian administration from 1898 until Sudan independence in 1956. Formal education, once entirely in the hands of Roman Catholic and Protestant missions, began to receive state aid in 1926. The Shilluk are headed by a divine king (*reth*) chosen from the sons of previous kings; his physical and ritual well-being is held to ensure the prosperity of the whole land. The large royal clan traces descent from the first king and culture hero, Nyikang (Nyikango). The

kingdom (capital, Fashoda) has two main provinces that are symbolically united at the king's installation, and are subdivided into settlements under local chiefs. *See* also NILOTES.

SHILOH, a town in Canaan where the tabernacle and ark were installed after the Israelite conquest. The site at Saylun (Seilun, in Jordan), 25 mi. N of Jerusalem, was partially excavated by the Danish archaeologists H. Kjaer and Aage Schmidt during 1926–32; they proved that the Philistines had destroyed Shiloh (*cf.* I Sam. 4) and that it remained for centuries in ruin (Jer. 7). For about a century and a half (1200–1050 B.C.) it was the chief centre of the Israelite tribal confederation, under a series of high priests, from Eleazar and Phinehas to Eli. (W. F. A.)

SHILOH, BATTLE OF. This, the second great battle in the American Civil War, also called the battle of Pittsburg Landing, was fought on April 6 and 7, 1862, between the Union forces under Gen. U. S. Grant and Gen. D. C. Buell and the Confederates under *Gen. A. S. Johnston* and *P. G. T. Beauregard.* (For clarity, the names of those fighting on the Confederate side are in *italics.*)

In February 1862 Grant had taken Ft. Henry on the Tennessee River and Ft. Donelson on the Cumberland. The Confederates had acknowledged the importance of these forts by abandoning their strong position at Columbus, Ken., and evacuating Nashville on the upper Cumberland. Grant then sought to extend his advantage by an amphibious move up the Tennessee to attack the line of the Memphis and Charleston Railroad, which followed the line of the upper river. High water frustrated these early efforts at raids from the river as a base. He then disposed his five divisions in camps around Pittsburg Landing on the Tennessee River near Corinth, Miss. There *Johnston,* commanding Confederate forces in the west, and *Beauregard* were collecting a force aimed at recovering some of their recent losses. Buell's army was marching somewhat leisurely across the country from Nashville to join Grant in an attack upon Corinth. Since they were planning for an offensive the Union troops had not fortified their camps. *Johnston,* to their surprise, seized the initiative and decided to attack Grant before Buell could arrive. Accordingly he led his army from Corinth against Pittsburg Landing early on Sunday morning, April 6.

This battle was fought by inexperienced troops on both sides. Gen. W. T. Sherman was holding the most exposed position at Shiloh Church about 2 mi. W of the Landing with recently recruited raw troops. The other Union divisions were scattered in several camps out of sight of each other. Sherman's men received the first assault and the two advanced divisions were swiftly driven in on the others, who had only a little more time to prepare themselves. Confederate leaders in the woods were unable to control and maneuver their untrained and excited men. But the Confederates continued to push each isolated Union division fighting hard toward the Landing. Thus the day passed in confused and savage scuffles between raw troops.

By late afternoon, Grant, who had come up from his headquarters at Savannah 9 mi. down the river, had rallied his troops. With one brigade of Buell's leading division, which had arrived on the previous evening, he formed a defense line in a naturally strong position barely 600 yd. from the Landing. Earlier in the afternoon *Johnston* had been killed, a sore and irreparable loss to the Confederate cause. At sunset *Beauregard,* as was customary, suspended the attack. During the night Buell brought up 25,000 troops and he and Grant took the offensive early the next day. *Beauregard* thereupon decided to extricate his hard-pressed army and to retire fighting toward Corinth. A strong rear-guard action under *Gen. Braxton Bragg* repulsed the attacks of Grant and Buell at Shiloh Church for six hours and the Union forces succeeded in doing little more than reoccupying the camp they had lost the day before while the Confederates returned to Corinth. It was a Confederate failure but not a Union victory and, each side being weakened by about 10,000 men, neither made any movements for the next three weeks.

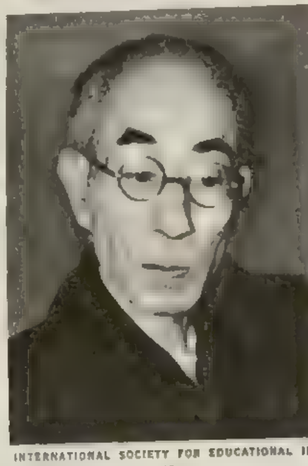
SHIMANE, a prefecture (*ken*) in southwest Honshu, west Japan. Area, including the island group of Oki-Guntō, 2,558 sq.mi. (6,625 sq.km.). Pop. (1965) 821,620. It is located on the Sea of Japan, distant from the central part of the country. Because of this location and its unfavourable natural conditions, Shimane's culture, notable in ancient times, and its industry have become retarded. Forests cover most of the land, and forestry and stock breeding are well developed. However, agriculture supports most of the population. Paddy fields are scattered throughout the prefecture. Matsue (*q.v.*), the prefectural capital, is known to the west through the writings of Lafcadio Hearn. The ancient shrine at Izumo is justly famous. (R. B. H.)

SHIMAZAKI TŌSON (1872–1943), Japanese poet and novelist, whose fiction does much to illuminate the clash of old and new forces in a Japan feverishly modernizing itself, and the unsettling effects of this collision on the intellectual. He was born in Nagano Prefecture on March 25, 1872, and educated at a Tokyo mission school where he was also baptized, although Chris-

tianity did not lastingly affect either his life or his thought. In the early 1890s he joined the short-lived "Romantic" movement of young poets and writers, which he later described in his novel *Haru* ("The Spring"; 1908). Most of his nature and love lyrics, still widely appreciated because of their authentic freshness, had already appeared by the turn of the century, as had a few essays and short stories.



INTERNATIONAL SOCIETY FOR EDUCATIONAL INFORMATION, TOKYO, INC.
SHIMAZAKI

The first of his major novels, *Hakai* ("The Broken Commandment"; 1906), the story of a young schoolteacher's vain fight against village obscurantism, has been called representative of the "Naturalist School," then the vogue in Japan, although it definitely reveals the influence more of Rousseau than of Zola. *Ie* ("The Family"; 1910) depicts his and his wife's relatives drifting from their rural home into the large city but, while escaping the rigour of the patriarchal system, acquiring no new certainties. *Shinsei* ("The New Life"; 1918) narrates in a manner that carries the confessional principle to embarrassing excesses the unsavory affair of a writer with his niece. Later essays and stories, including exquisite tales for children, reveal an increasing maturity of style.

After remarrying in 1928, Shimazaki began research for the novel that was to be his greatest work as well as one of the masterpieces of modern Japanese literature, *Yoake Mae* ("Before the Dawn"; 1935). This is a story of the struggle for the imperial restoration in the 1860s as mirrored in a rural community, the tragic hero of the novel, faithfully modeled after the writer's own father, dying an embittered death, convinced that the cause of pure patriotism had been betrayed by the glib modernizers of post-Restoration Japan. Of a final novel, *Tōhō no Mon* ("Gate to the East"), only the first few chapters appeared in a monthly journal during the period just before his death, on Aug. 22, 1943. The fragment seems to invoke the Buddhist wisdom of medieval Japan as a way out of the impasse of the present. None of Shimazaki's work has been published in English. (J. Rf.)

SHIMOGA, a town in Mysore, India, and the administrative headquarters of the district of the same name, lies on the left bank of the Tunga River, about 150 mi. (241 km.) NW of Bangalore by rail. Pop. (1961) 63,764. Educational institutions include an engineering college and a degree-granting college, both affiliated to Mysore University. The town has rice and oil mills, and cotton spinning and pressing factories; handloom cloth production is a cottage or family unit type industry. It is also a trading centre, reexporting areca nuts, rice, coffee, and pepper.

Shimoga District has an area of 4,066 sq.mi. (10,531 sq.km.). Pop. (1961) 1,017,368. In the east it is drained by the twin rivers Tunga and Bhadra which unite at Kudli and join the Kistna (Krishna) River as the Tungabhadra. In the west the district is drained by the Sharavati River, which, before it enters the western coastal plain, forms a magnificent cataract, the Gersoppa Falls. The watershed of the Tungabhadra and Sharavati river basins lies on the western edge of the Ghats. The western half of the district, which is mountainous and forested, is known as *malnad* or hill country. Coffee is grown on the hill slopes and the valley bottoms are given over to the cultivation of rice and sugarcane. The eastern half of the district is open, undulating country and there dry crops such as cotton, millet, and oilseeds are grown. Natural resources include iron ore, limestone, and manganese. Bhadravati (pop. [1961] 24,495), on the Bhadra River, is an industrial centre with an iron and steel plant and a paper mill. At Gersoppa there is a hydroelectric works.

In the 16th century Shimoga was under the Keladi chiefs. In 1763 it was annexed by Haidar Ali, being finally brought under British administration in 1830. (G. K. Gh.)

SHIMONOSEKI, largest city of Yamaguchi Prefecture in extreme western Honshu, Japan. Pop. (1965) 254,380. Its strategic location on the Straits of Shimonoseki brought it to transportation and commercial prominence. The city was formerly called Akamagaseki or Bakan. Modern development began in 1905 with the opening of railroad ferry service with Moji in Kyushu; more recent links include a 2.3 mi. (3.7 km.) railroad tunnel (1942) and a vehicular-pedestrian tunnel (1958) under the straits. Shimonoseki became a heavy industrial centre after 1942 and in 1940 its port was formally amalgamated with Moji (*see* Kita-Kyushu) and Kokura ports into the single port of Kammon.

The Straits of Shimonoseki (Shimonoseki-kaikyō), renamed Kammon Straits, are the narrow western passageway between Japan's Inland Sea and east Asian waters. Although about 2,200 ft. (670 m.) wide at the narrowest point and partially blocked by Hiko Island at the western end, the straits are 40–65 ft. (12–20 m.) deep and are easily navigable. (J. D. Ee.)

SHINGLES: *see* Skin, Diseases of.

SHINNECOCK, a North American Indian tribe whose aboriginal home was the eastern end of what is now Long Island, N.Y. In the 17th century they were part of the Montauk Confederacy, along with such fellow Algonkian tribes (*q.v.*) as the Manhasset, Massapequa, Montauk proper, Patchogue, and Rockaway. During this period the confederacy was attacked and dominated from the north, first by the Pequot and later by the Narraganset, and suffered serious additional population losses through epidemic disease. Most of the survivors organized to form the Brotherton tribe, moving in 1788 to lands near Marshall, N.Y., donated by the Oneida (*q.v.*). Descendants of those members of the Montauk Confederacy who remained on Long Island are recognized by New York State as the Shinnecock tribe. In the 1960s, having lost almost all their earlier customs and language through acculturation (*q.v.*) and marriage with Negroes, about 150 people officially called Shinnecock lived on their reservation near Southampton, N.Y.

Westez, "Surviving Folk Tales and Herbal Lore Among the Shinnecock Indians of Long Island," *Journal of American Folk-lore*, vol. 58 (1945); L. M. Hunter, *Shinnecock Indians* (1950); F. W. Hodge (ed.), *Handbook of American Indians North of Mexico*, 2 vol. (1959).

SHINRAN (called Shinran Shōnin, "St. Shinran") (1173–1262), founder of Jōdo Shinshū (True Pure Land School, Shin Buddhism), the representative school of devotional Buddhism that arose in the Kamakura period and remains one of the chief Japanese Buddhist sects, was born in Kyōto, the son of Arinori Hino, a member of the illustrious Fujiwara family which ruled Japan during the Heian period. Orphaned at an early age, Shinran entered a monastery on Mt. Hiei in Kyōto and began intense religious training in the Tendai tradition. After 20 years, realizing his inability to purge himself of ignorance and human passions, he became a disciple of Hōnen (1133–1212), founder of the Jōdo, or Pure Land School. Hōnen taught that because Amida Buddha's vow of salvation was universal and unconditional, it was not through good works but through the exclusive recitation of Amida's name (*Namu Amida Butsu*) that man could attain to Buddhahood. The sudden popularity of the new doctrine aroused the jealousy of the established schools, and Hōnen and some of his disciples were banished. Shinran continued his ministry in distant provinces, marrying and thus breaking the age-old rule of celibacy for the priesthood. In 1224 he completed his main work, the *Kyō-gyō-shin-shō*, in which he systematized his unique teaching, Jōdo Shinshū. He not only accepted Hōnen's doctrine but also sought to refine it by setting forth the significance of faith—which was, according to Shinran, itself a gift from Amida Buddha—as the true cause of birth in the Pure Land after death. In clarifying Hōnen's concept of the *Nembutsu* (reciting the Holy Name), he stated that the recitation was the spontaneous expression of one's innermost joy and gratitude and not the means to accumulate merit.

Shinran developed the Pure Land School to its utmost simplicity in order to reach all levels of people. Shin Buddhism became one of the most popular schools of Buddhism in Japan. In accordance with the progressive and liberal attitude of its founder, it has involved itself in extensive educational and social welfare programs.

Since the late 19th century it has gone beyond its native boundaries and established itself abroad, especially in the Americas, where numerous congregations are to be found.

English translations are available of Shinran's *Kyō-gyō-shin-shō* ("Teaching, Practice, Faith and Attainment"), by Kōshō Yamamoto, with notes (1958), and, separately, of his *Shō-shin-ge* ("Gāthā of True Faith"), by Daien Fugen, also with notes (1961). His *Wasan* (more than 350 verses in praise of Buddha), translated by Yamamoto, are included in the *Shinshū Seiten* (1955). The *Tannishō*, compiled by one of his disciples but including many important sayings of Shinran, has been translated into English and other European languages. Shinran's *Private Letters* also have been translated by Yamamoto (1956).

SHINTŌ, which literally means the way or teaching of the gods (*kami*), is the loosely organized, indigenous religious cult of Japan. This designation arose in order to distinguish the traditional religion from Buddhism when the latter was introduced to Japan in the 6th century A.D. While Shintō has no founder, no official sacred scriptures, and no dogma, it has preserved its ethos throughout the ages. In the modern period it has been used as a tool of ethnocentric nationalism and chauvinistic militarism, and it is often thought of in these terms by outsiders.

Primitive Shintō.—Even before the historical period the inhabitants of Japan had some kind of religion, but the origins of the ancient cult that gradually developed and was later called Shintō are unknown. The ancient Japanese people were an admixture of various groups who had migrated to the Japanese islands from the Asian continent, and their religion betrayed northern and southern Asian influences. It took several centuries for these ethnic groups and peoples to become assimilated under the leadership of the so-called Yamato clan, about the 4th century A.D. The early Japanese myths, which are often unrelated and contradictory, indicate that they were in part the legacy of the dominant Yamato clan and in part the sacred traditions of other clans and peoples that were subjugated by the Yamato.

The early Japanese by and large did not distinguish sharply between the celestial and earthly domains. They had only a vague notion about the life to come, and the veneration of ancestors that characterized religious life later was hardly known. Their religion was a simple polytheistic nature worship, emphasizing gratitude to the beneficent forces of nature, while also to some degree appeasing the malevolent forces. These forces were indiscriminately called *kami*, usually translated as "gods" or "deities" but meaning "above," "superior," or "divine," and signifying anything that was the object of reverence and respect. Accordingly, all the heavenly and earthly forces, great men both living and dead, and many animate and inanimate beings such as plants, rocks, birds, beasts, and fishes as well as earthquakes, thunder, water, sun, and moon were *kami*. The early myths spoke of 800 myriads of *kami*, usually divided into heavenly *kami* (those who resided in the heavenly abode) and earthly *kami*. The Japanese did not regard spirit as superior to matter; rather, they believed that the two coexisted as equals. *Kami* were thus regarded as inseparable from *shintai* (*kami-* or god-body) or *mitama-shiro* (visible representations of *kami*). The religious rites of the early Japanese were mostly fertility cults. Ceremonial purification was emphasized. Three kinds of persons performed religious rites: (1) the heads of families or clans, considered priests *de facto*; (2) shamans (*see* SHAMANISM) who performed divination, sorcery, and lustration; and (3), in at least some clans, hereditary lines of priests and shamans. When the Yamato clan overpowered the other clans its hereditary priest-king (Tennō or "emperor") acquired supreme prestige. Significantly, the function of the throne was to take charge of both religious rites (*matsuri*) and political administration (*matsuri-goto*), which were regarded as inseparable.

With the ascendancy of the Yamato clan its myths began to provide foundations for political theories. (*See* JAPANESE MYTHOLOGY.) Their prominent feature was the divine origin of the Yamato people in the sun-goddess, whose grandson, Ninigi, was said to have been the grandfather of the first emperor, Jimmu Tennō, the earthly ancestor of the imperial family. The sun-goddess was later enshrined at the Grand Shrine of Ise, which became both the tutelary shrine of the imperial family and the central shrine of the whole nation (*see* ISE). Eventually the myth of the solar ancestry of the imperial clan was widely accepted among the various clans, including many of Chinese and Korean descent. The sun-goddess was worshiped side by side with other clan deities and nature deities, all of them comprising a rich Shintō pantheon. While in the history of Japan the political authority of the throne was often precarious, it never lost its bond with the masses because of Shintō, which was rooted both in the religious tradition of the imperial clan and in the sacred memories of other clans.

Foreign Influences.—With the introduction of Chinese civilization in the 5th century A.D., the religious and cultural situation in Japan became complex. Confucianism not only provided Japan with systematic theories of social and political institutions but also with ethical norms for individuals, ranked in a hierarchical society. With Confucianism came Taoism and the Yin-Yang philosophy, and they too contributed philosophical concepts. (*See* CONFUCIANISM; TAOISM.) Gradually, Confucian moral virtues began to be attributed to Shintō deities, and imperial edicts stressed such Confucian virtues as uprightness, sincerity, and honesty as guiding moral principles. The concepts of filial piety and the veneration of ancestral spirits were soon adopted by the Japanese.

Buddhism (*q.v.*), introduced to Japan in the 6th century A.D., also had far-reaching influence, becoming in the 7th century for all practical purposes the state religion. Shintō, however, retained its prestige and influence among the masses, and a government department of Shintō was established to manage and control the festivals and rites at the imperial household as well as at the tutelary and ancestral shrines of powerful clans. The cause of Shintō was greatly enhanced by the compilation in the 8th century of the *Kojiki* and the *Nihongi* (*qq.v.*), in which the ancient oral traditions were assembled and recorded for the first time. Since Chinese script was used, the myths and legends were inevitably influenced by Chinese thought; nevertheless, these records are an important storehouse of early Japanese myths and they are often considered as quasi-sacred scriptures of Shintō, although Shintō has no concept of scripture comparable to the Bible or the Koran.

Coexistence of Buddhism and Shintō.—Buddhism began to overshadow Shintō during the Nara period (8th century A.D.), especially in the capital city of Nara, but it had to come to terms with the deeply rooted Shintō beliefs and practices of the people. Even the construction of the Tōdaiji, the national cathedral of Buddhism at Nara, required the blessing of the Shintō deities, communicated to the throne by means of oracles; and emperors and empresses who considered themselves humble slaves of Buddha could not neglect the Shintō rites altogether. Buddhism and Shintō did not attempt to exterminate each other. What emerged was a pattern of coexistence that is often referred to with some exaggeration as the amalgamation of Shintō and Buddhism.

This pattern developed gradually. For example, wealthy land-owning Buddhist monastic institutions found their tenants deriving solidarity from Shintō deities and Shintō cults; by allowing Shintō shrines to remain, the Buddhist institutions were protected by Shintō taboos. Eventually, Shintō shrines found their way into the sacred premises of Buddhist temples and monasteries, and in turn Buddhist chapels were built near Shintō shrines. During the Nara period Buddhism became so powerful in the court that Shintō had nothing to lose by allying itself with Buddhism. Even the popular Shintō deity Hachiman came to be known as *Daijizaiten-bosatsu* (Bodhisattva).

When the capital was moved from Nara to Heian-Kyō (the present Kyōto) toward the end of the 8th century, ostensibly to be freed from the political pressure of Buddhist institutions, the pattern of coexistence persisted. As early as 794, Buddhist sacred

scriptures were recited at some Shintō shrines. Two new Buddhist schools, Tendai and Shingon, inaugurated in the 9th century not only welcomed an alliance with Shintō but also attempted to provide theoretical justification for coexistence. The Shingon Buddhist theory was called Ryōbu ("Two Aspects") Shintō, the Tendai theory Ichi-jitsu ("One Reality") Shintō. Both interpreted Shintō deities as manifestations or incarnations of the Buddha, and each attempted to incorporate Shintō into its framework of Buddhism. Shintō priests were dominated by the Buddhist ecclesiastics and had to be content to play only a minor role even in Shintō rites. Shintō continued to enjoy favour among the masses in the outlying districts, and the folk elements of the Shintō tradition were represented in the Shugen-dō (order of Mountain Priests), but during the middle of the Heian period the Shugen-dō also allied itself with the Tendai and Shingon Buddhist schools.

Shintō Reaction Against Buddhism.—During the Kamakura period, which succeeded the Heian, the feudal regime (*bakufu*) ruled by warrior-statesmen (*shōgun*) was established, and courtly elegance gave way to the austere culture of warriors. Moreover, after centuries of peace and tranquility, Japan was threatened by the Mongols. But this period, with its social and political disruption, was an age of spiritual awakening reflected in Shintō by an attempt to emancipate itself from the domination of the Tendai and Shingon schools. The spokesmen for Shintō were hereditary priests of the Watarai family who served at the Outer Shrine of Ise; hence the movement was called Ise Shintō. Buddhism was too deeply rooted to be rejected altogether, and recognizing this, the spokesmen of the Ise Shintō movement attempted to reverse the Buddhist claim that Shintō deities were incarnations of the Buddha; they taught instead that Buddhas and Bodhisattvas were manifestations of the great *kami* nature of Shintō. By the middle of the Kamakura period the five-volume apologetic work, *Shintō Gobushō* ("Shintō Pentateuch"), was completed.

The decline of the Kamakura feudal regime was followed by a period of imperial rule which greatly encouraged the Ise Shintō movement. The historian Kitabatake Chikafusa (*q.v.*) wrote in his *Junnō Shōtōki* (1369), "Great Yamato is a divine nation. It is only our land whose foundations were first laid by the divine ancestor. It alone has been transmitted by the sun-goddess to a long line of her descendants." The short-lived imperial rule was followed by the Ashikaga feudal regime, during which, with some notable exceptions, Shintō was again at a low ebb. A monotheistic view developed, formulated by Ichijō Kanera (d. 1481) and by Yoshida Kanetomo (d. 1511), who, deeply influenced by Taoist metaphysics, initiated Yoshida or Yui-itsu ("One and Only") Shintō, teaching that one unique *kami*-nature is the underlying substance of all Shintō deities and Buddhas. The influence of Shintō, however, was negligible during the Ashikaga period and the "dark age" that followed it.

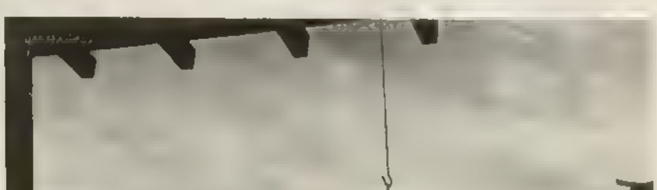
Confucian Shintō.—Japanese unification was completed with the establishment of the Tokugawa feudal regime early in the 17th century. While the Tokugawa rulers gave financial support and certain prerogatives to both Buddhist and Shintō clergy, ecclesiastics were strictly governed by the "commissioner of temples and shrines" appointed by the regime, and the guiding ideology of the regime was the Chu Hsi school (Shushi-gaku) of Neo-Confucianism (*see* CHU HSI; CONFUCIANISM). Curiously enough it was the Confucian scholars of this period who allied themselves with the cause of Shintō and eventually brought about the Shintō revival. (*See* further JAPANESE PHILOSOPHY: *Philosophy Before the Modern Period: Search for a New Universal Principle.*)

Shintō leaders welcomed an alliance with Neo-Confucianism, which provided the cosmology that was lacking in traditional Shintō. Deguchi Nobuyoshi (d. 1690) attempted to interpret Shintō according to the Confucian classic *I Ching* ("The Book of Changes"). Kikawa Koretaru (d. 1694) identified the "Supreme Ultimate" of Chu Hsi with a Shintō deity, Kuni-tokotachi, whose name now meant the Cosmic Lord and the Reason of Heaven. Meanwhile, under the leadership of Yamazaki Ansai (*q.v.*), a new movement called Suika Shintō emerged. This school identified the Supreme Ultimate of Neo-Confucianism with two Shintō deities, Kuni-tokotachi and Ameno-minaka-nushi, who in turn were regarded as essentially one reality which is both the substance of the universe and the source of morality; and the sun-goddess is their incarnation. Yamazaki taught the importance of devotional prayer and the virtue of honesty and advocated an extreme respect for the emperor. Similar emphasis on respect for the emperor was taught by the Mito school of Neo-Confucianism, laying the foundation for the loyalist movement later.

Shintō Revival.—The revival of Shintō studies developed gradually in the 18th century along with the study of the Japanese classics. Stimulated by philological research in ancient Japanese poetry, scholars of the Koku-gaku ("Japanese studies") such as Kamo no Mabuchi (1697–1769) devoted themselves to the study of the *Manyōshū*, a collection of ancient poems, and *Norito*, a collection of old Shintō liturgies. Rejecting both the Buddhist- and Confucian-centred interpretations of Shintō, Kamo tried to restore its pre-Buddhist and pre-Confucian meaning. Unconsciously espousing the Taoist ideal, he stressed pure simplicity, in accordance with the order of heaven and earth, as the best morality.

Kamo's disciple Motoori Norinaga (1730–1801) rejected this Taoist-oriented interpretation and insisted that Shintō was based on the revelation of *Takami-musubi-no-kami* ("August Producing Deity") transmitted by the sun-goddess. Motoori is credited with the most systematic interpretation of the concept of *kami* as "anything whatsoever which was outside the ordinary, which possessed superior power or which was awe-inspiring." In 1798 he completed his voluminous commentary on the *Kojiki*, which has remained the authoritative interpretation of the theoretical aspects of Shintō.

Another noted Shintō scholar, Hirata Atsutane (1776–1843), a Confucian scholar before he was



BY COURTESY OF CONSULATE GENERAL OF JAPAN, N.Y.

(LEFT) LANTERNS AT KASUGA SHRINE; (ABOVE) ITSUKU-SHIMA SHRINE

Both Itsuku-shima and Kasuga shrines are ancient, dating back to the 9th and 8th centuries respectively. The island shrine of Itsuku-shima, in Hiroshima Bay, has been rebuilt several times, always according to the original plans. The 3,000 bronze lanterns of Kasuga Shrine, at Nara, were placed by worshipers as offerings to the deities.

influenced by Motoori's writings, tried to systematize Shintō "theologically" by holding *Ame-no-minaka-nushi* ("Heavenly Central Lord") as the creator god, viewed above the sun-goddess. He also developed an eschatological concept within the Shintō framework. His *Hongyō-gaihen* ("Supplemental Compilation of Shintō," 1806) is divided into two parts, one based on writings of the Jesuit Matteo Ricci (*q.v.*), who wrote in Chinese, the other on selections from a manual of Christian ethics written in 1614 by another Jesuit missionary in China, Didace de Pantoja. Hirata's thought was to have a great influence on the development of modern Shintō.

Toward the end of the Tokugawa period, the folk elements of Shintō began to break through its traditional framework. The Konotabi movement, inaugurated by an illiterate peasant woman, Kinō (d. 1826); the Tenrikyō movement, founded by another peasant woman, Miki (d. 1887); and the Kurozumi-kyō movement, initiated by an obscure Shintō priest, Kurozumi Munetada (d. 1849), were but a few examples of this dynamic religious awakening among the poor and oppressed. (*See* below, *Sect Shintō.*) They were destined to play important roles in subsequent periods. Meanwhile, these messianic movements among the peasantry were looked down upon as impure Shintō by the orthodox hierarchy and scholars.

Shintō as the National Faith.—In 1867 the modern age began in Japan. The Meiji regime that followed the Tokugawa shogunate had two diametrically opposed aims—the revival of the ancient Japanese pattern of *saisei-itchi* (unity of religion and the state) and the modernization of Japan. In 1868 the department of Shintō (*Jingi-kan* or *Shingi-kan*) was established and immediately issued a separation edict intended to abolish the age-old pattern of Shintō and Buddhist coexistence. Buddhist priests who had been connected with Shintō shrines were given the choice of returning to lay life or being re-ordained as Shintō priests. The traditional custom of burying Shintō priests according to Buddhist funeral rites was forbidden, and a new Shintō burial office was introduced. In 1869 the department of Shintō was made independent of the cabinet and placed above the grand council of state. In 1871 Shintō was proclaimed the national religion and Shintō shrines were decreed to be the place of worship for all subjects of the emperor. All Shintō priests were to be appointed by the government. To counteract movements to restore the feudal regime, the government began to advocate emperor worship. But the measures taken to uphold the supremacy of Shintō at the expense of Buddhism failed: Buddhism was too deeply imbedded in the fabric of Japanese life.

The department of Shinto was replaced during 1872–77 by the ministry of religion and education (*Kyōbu-shō*), which was given jurisdiction over both Shintō and Buddhism. In 1873 the edict banning Christianity was lifted. Recognizing the impossibility of suppressing the growing tide of spontaneous folk religious movements, the government in 1882 decided to classify them as Sect Shintō, to be differentiated from Shrine Shintō, which had about 200,000 large and small shrines throughout the nation. The constitution promulgated in 1889 included a clause guaranteeing freedom of religious belief, but the government continued to favour Shintō, not so much as a religion but as a national cult. In 1900 shrines and religions were placed in separate bureaus, and in 1913 the religious bureau was transferred to the ministry of education

In a real sense, modern Japan was caught between its two objectives. One of these, to reestablish the ancient system of *saisei-itchi*, drove Japan to assert the centrality of Shintō as the national religion. The second, modernization, however, drove it to pay lip service to freedom of religious belief. Toward the end of the 19th century an uneasy compromise was worked out, based on the theory that Shintō was not a religion but a suprareligious national cult, and as such could be superimposed on the nation. The emperor cult was almost arbitrarily devised and a course in *shūshin* ("moral teaching") was made the basis of compulsory education. Beginning with the Chinese-Japanese War (1894–95), Japan followed an expansionist policy, and from that time until World War II Shintō was manipulated by the militarists and jingoistic nationalists as the spiritual weapon for mobilizing the nation to guard the prosperity of the throne.

Shintō After World War II.—State Shintō was disestablished immediately after World War II. Orders from the supreme commander for the Allied powers to the Japanese government stated explicitly that:

> The sponsorship, support, perpetuation, control, and dissemination of Shintō by the Japanese nation, prefectural, and local governments, or by public officials, subordinates, and employees acting in their official capacity are prohibited and will cease immediately; all financial support from public funds and all official affiliation with Shintō and Shintō shrines are prohibited and will cease immediately.

Equally drastic was the abolition of *shūshin* from the school curriculum and the emperor's public statement:

> The ties between Us and Our people have always stood upon mutual trust and affection. They do not depend upon mere legends and myths. They are not predicated upon the false conception that the emperor is divine and that the Japanese people are superior to other races and are fated to rule the world.

Although the emperor cult was thus abolished, the time-honoured tradition of imperial family Shintō continues. Four shrines have been set aside for the imperial household rites, the most important among them being the *Kashiko-dokoro*, dedicated to the sun-goddess, a branch of the Grand Shrine of Ise.

Organization and Worship.—With disestablishment, Shintō shrines lost their financial subsidies from public funds. Of about 110,000 shrines governed before the war by the home ministry, over two-thirds came to belong to the Association of Shintō Shrines (*Jinja Honchō*); the rest are either independent or belong to small local associations.

Many Shintō priests are so by heredity, but anyone with proper training can become a priest. The main training centre is Kokugakuin University in Tokyo. From the Meiji period until the end of World War II, Shintō priests were government officials, graded into several ranks. After the war they had to be supported by income from their shrines and other offerings from the laity. Each shrine has *ujiko* (parishioners), whose representatives act as a governing board for shrine affairs. In addition, *sūkeisha* (worshipers who are not regular parishioners) are welcome to participate in the ceremonies at any time. Many shrines have started various kinds of social welfare work, and Shintō wedding rites are popular.

There are numerous types and kinds of shrines, from the Grand Shrine of Ise, with its 14 subsidiary shrines, to small obscure roadside oratories unattended by a priest. Before disestablishment, shrines were classified as national, special national, governmental, prefectural, and district or village shrines, besides about 63,000 shrines "without rank." Most shrines are dedicated to deities, but some are dedicated to historical figures such as Emperor Meiji and General Nogi Maresuke. Most of the special national shrines enshrine the spirits of persons who made conspicuous contributions to the nation. Genealogies of deities enshrined in rural Shintō shrines reveal varied backgrounds.

The shrines assume various forms, but most are built in scenic surroundings. The two main units are an inner sanctuary (*honden*) and an oratory (*haiden*). According to Shintō, deities are present in the *shintai* (*kami-* or god-body) or in the *mitama-shiro* (visible representation of *kami*) which is kept in the inner sanctuary. A shrine dedicated to mountain or forest deities, however, has no need of an inner sanctuary. Usually, only the priests and their attendants are permitted to approach the inner sanctuary, where they recite prayers. Larger shrines have additional buildings, such as a hall of reciting prayers (*norito-den*), a hall of offerings (*hei-den*). and a hall of liturgical dance (*kagura-den*).

The entrance to the shrine is marked by a *torii*, a simple gate marking off the sacred compound. Worshipers wash their hands and rinse their mouths at an ablution basin (*te-mizu-ya*) and then approach the oratory, bowing reverently to the inner sanctuary and clapping their hands. A small offering to the deities is usually made. On special occasions the priest may be asked to perform a simple rite of purification (*harai*) in which a branch of the sacred tree (*Cleyera japonica*, an evergreen of the tea family) is waved three times before the worshiper, after which he makes offerings and secures charms at the shrine office.

Parishioners (*ujiko*) belong hereditarily to certain shrines, in the sense that the deity of a given shrine is the tutelary *kami* for all members of the *ujiko*. But priests have no pastoral relation

with *ujikos*, their main duty being to serve the deities and offer prayers. Shintō religious activities are not confined to the shrines. The traditional Japanese family performs a simple daily rite before the family *kami*-shelf (*kami-dana*), dedicated to the family's tutelary deity.

Shintō prayers (*norito*) are based on the ancient belief that the spoken word has a spiritual potency; therefore the prayers must be recited reverently. Prayers usually include, in elegant classical language, words of praise for the deities, lists of offerings, and petitions. The norms of Shintō rituals and prayers are found in the *Engi Shiki* ("Ritual Notes"), a 50-volume work compiled in the 10th century.

Festivals.—Before 1945 most national holidays were based on Shintō festivals: New Year's day, when at the imperial court and elsewhere people worshiped in the four directions; Empire Foundation day (Feb. 11), the day when the first emperor, Jimmu, is supposed to have been enthroned; the Spring Season Imperial Spirit festival (spring equinox); the Anniversary of the Death of Jimmu (April 3); the Autumn Season Imperial Spirit festival (autumn equinox); the Festival of the Presentation of First Rice to the Deities at the Grand Shrine of Ise (Oct. 17); and the Autumn Thanksgiving festival (Nov. 23). After 1945 some of these holidays lost their religious meaning, but they remained holidays. For example, Nov. 3, previously set aside to commemorate the great achievement of Emperor Meiji, became the National Day of Arts and Culture, while Nov. 23, the traditional day of the Shintō festival at the sanctuary of the imperial household, became the Japanese Labour Day.

Doctrine.—Throughout its history Shintō has been conspicuously indifferent to any theoretical systematization of its beliefs. Though there exist movements to formulate a coherent theological system, none has been widely accepted. Such central concepts as *kami*, *musubi* (creating and harmonizing power), *makoto* (truthfulness), and *harai* (purification) are integrated into the total Shintō way of life and worship. Probably the genius of Shintō lies in its refusal to formulate a *summa theologica*. An ancient Japanese poem expresses its nebulous but genuine religious sentiment: "Unknown to me who resideth here; tears flow from a sense of unworthiness and gratitude."

Sect Shintō.—Throughout its long history, Shintō has been supported by the folk piety of the masses, uninterested in complicated concepts and theories of religion. The common people of Japan developed arts and crafts to a high degree, and they had a vivid poetical sense and appreciation of the mystery of life and the universe. Living close to nature, they invoked deities of all sorts, depending on their physical and spiritual needs. Divination, spirit possession, protection from misfortune and disease, and magical formulas for other benefits played important roles in popular belief and practice, and they infiltrated official Shintō and Buddhism as well. In times of social unrest or natural calamity this folk piety was often intensified and supported various messianic movements, which frequently became established and eventually assimilated into Shintō or Buddhism. The 19th century, a period of social upheaval and transition, witnessed the emergence of many such messianic movements. Between 1882, when these popular cults were separated from the suprareligious national cult and classified as Sect (Kyōha) Shintō, and 1908, 13 Sect Shintō denominations came to be recognized as "churches" (*kyōha* or *kyōkai*), dependent, like Buddhist sects and Christian denominations, on private initiative for their propagation, organization, and financial support. Not all of the 13, however, were Shintō in origin or in ethos.

Usually the Sect Shintō denominations are classed as follows: (1) Pure Shintō sects based primarily on certain Shintō beliefs and practices and emphasizing loyalty to the throne and gratitude to ancestors; (2) Confucian sects, which blend Confucian moral doctrines and certain Shintō beliefs; (3) Mountain sects, which hold that their deities reside in certain sacred mountains; (4) Purification sects, which stress mental and physical purification from evil and contamination; and (5) Utopian or Faith-Healing sects. The denominations have little in common. Some of them worship certain traditional Shintō deities and add others of their own; the Konkō-kyō sect, however, has no Shintō deities, and the god of Tenri-kyō is not included in the Shintō pantheon. Most active among the 13 denominations is the Tenri-kyō, which boasts of more than 500 churches overseas, in addition to its well-organized ecclesiastical institution in Japan.

Most adherents of Sect Shintō sought worldly benefits, such as cures for sickness, protection from disasters and misfortunes, wealth and success in life, which traditional Shintō as well as Buddhism failed to offer. Gradually, however, the new denominations tended to become institutionalized and less concerned with the immediate needs of their adherents. The people began to look for new prophets and shamans, creating a number of small splinter groups within the denominational framework. These splinter groups were emancipated from their parent bodies after World War II and initiated the postwar boom of "New Religious Cults" (*Shinkō Shukyō*). An extremely precarious relationship exists between the Sect Shintō denominations, now organized as the Federation of Sect Shintō, and the New Religious Cults. *See* also JAPAN: *History* and *The People: Religion*.

SHINYANGA REGION, TANGANYIKA, established in May 1963 following a reorganization of administrative units in Tanganyika (Tanzania), comprises Shinyanga and Maswa districts, which previously belonged to the former Lake Region, and Kahama District, which previously belonged to the former Western Region.

The region is bounded north by West Lake, Mwanza, and Mara regions, east by Arusha Region, south by Singida and Tabora regions, and west by Kigoma Region. Area 19,600 sq.mi. (50,764 sq.km.). Pop. (1963 est.) 749,000. The region lies on the central plateau of Tanganyika across the ill-defined watersheds between the Lake Victoria Basin to the north, the Malagarasi River system to the southwest, and the Wembere Depression and Lake Eyasi in the eastern rift to the east. The plateau is largely composed of granites with hills of banded ironstone of Nyanzian Age. Maswa District extends eastward to include part of the Serengeti National Park. Mean annual rainfall ranges from less than 20 in. (500 mm.) in Maswa District to more than 40 in. (1,000 mm) north of Kahama, the rain falling mainly during the period from November to April. Soils include old lacustrine soils, sandy clay loams on slopes, black clays in valley bottoms, and some with a lateritic horizon.

Regional headquarters are at Shinyanga, and the population is most dense in Shinyanga District, which is famous for the Williamson Diamond Mine. Shinyanga and Maswa districts, which form part of Sukumuland, are characterized by an intensive agricultural economy based on cattle and the cultivation of cotton. The Nyamwezi and Sumbwa tribes predominate in Kahama District, in the western part of which the population is relatively sparse and the tsetse fly is prevalent. Maize, sorghum, and millet are among the staple food crops. (J. M. KE.)

SHIP, the vehicle by means of which man conveys himself and his goods by water; more precisely, the larger and more seaworthy of such vehicles, the smaller and simpler being boats. To merit classification as a ship or boat it is necessary for the vessel to support weight, not merely because of the buoyancy of the material of which it is made, but because of its displacement of water. (Structures depending only on their inherent buoyancy are rafts, or, in their simplest form, floats.)

After an initial discussion of the various kinds of shipbuilding and the limits of this discussion, the article is divided into the following sections:

For the practice and theory of modern shipbuilding, *see* NAVAL ARCHITECTURE; MARINE ENGINEERING. *See* also SHIPPING. For ships in naval history, *see e.g.*, AIRCRAFT CARRIER; DESTROYER; articles on battles and wars, and sections on history in articles on countries. *See* also separate articles on types of ships, such as CANOE; GALLEY; etc.

All kinds of ships, from the most primitive to the most modern and elaborate, can be classified under six heads: (1) rafts (floating logs or bundles of reeds, etc., either singly or connected to form a platform); (2) dugouts (hollowed trees); (3) canoes of bark or skin with an internal framework; (4) canoes or boats formed from planks stitched together; (5) vessels with planking nailed together and with a framework inserted; (6) vessels of which the framework is first set up and the planking (or plating) attached afterward. These classes sometimes shade into one another.

Rafts were no doubt used in all parts of the world at a certain stage of local culture. As seagoing craft in modern or comparatively recent times they are best known from the catamarans of India and the balsas of South America. The Ecuadorian balsa was a large sailing raft fitted with something like the modern centreboard. Its seaworthiness was sufficiently proved in 1947, when a party of Norwegian scientists, wishing to test a theory with regard to the peopling of the Pacific islands, built a similar raft, the "Kon-Tiki," at Callao, Peru, and succeeded after a voyage of three and one-half months in reaching the islands east of Tahiti. Dugouts are still characteristic of East Indian and Polynesian waters, bark canoes are (or were) chiefly North American, skin boats belong to the arctic, and the practice of building with sewn planks can still be observed in the East Indies. The two last classes correspond to the clinker building and carvel building of modern European small craft.

The following survey deals only with what may be called European ships, though this has to include the whole of the Mediterranean and, in later times, the shipping of North America. Eastern, Far Eastern (especially Chinese) and Polynesian craft form subjects of their own. (*See* BOAT: *Existing Boat Types*.)

The more or less standardized European full-rigged sailing ship was produced in the 15th century by the combination in a single vessel of characteristics derived from two almost distinct lines of descent, one from the Mediterranean and the other from northern and western Europe. Roughly speaking, construction came from the south and rig from the north. After this combination—from about 1460 to the last days of deep-water sailing ships—the European ship, in spite of a constant process of modification and improvement, remained unchanged in essentials.

It must be remembered that the southern line was very much older than the northern, or at least that it had reached a stage of comparative maturity much earlier. At the beginning of the Christian era the Mediterranean ship had a history of about 3,000 years and its builders had been producing more and more elaborate vessels for many centuries, while their fellow craftsmen in the north had only just evolved the method of building with keel, stem, sternpost, and planks and in so doing passed the line separating the mere canoe from the potential ship.

I. EARLY CRAFT

1. Origins.—The earliest knowledge of boats and ships comes from Egypt, where as early as 4000 B.C. boats were already far advanced from the primitive form from which they must have been derived, in this case probably a bundle of reeds. It has been claimed that "naval architecture is an Egyptian art and that the main lines of the history of ship-building for the whole world were laid down in Egypt towards the end of the 4th millennium B.C." (Elliot Smith, *Ships as Evidence* [1917]). There is, however, at least one extremely weighty objection to this sweeping claim—the fact that the Egyptian method of construction was not transmitted to the neighbours and successors of that kingdom. Egyptian vessels were essentially built-up dugouts (to use a contradiction in terms); they had no keel, stem, or sternpost and no internal framing, but consisted simply of a heavily built skin formed of many pieces of timber doweled or dovetailed together. With regard to matters of equipment such as mast and sail or steering gear, the claim is more easily substantiated.

Unfortunately, comparatively little is known of the ships of the Cretans, who were the dominant sea power in the eastern Mediterranean about 1500 B.C., or of the Phoenicians, who took their place; but that little suggests that both nations had begun to differentiate between the fighting vessel and the merchantman and between the rowing galley and the sailing ship. The few representations of Phoenician vessels (about 700 B.C.) do, however, illustrate two striking developments: the arrangement of oars in two banks at different levels and the fitting of a ram bow in galleys intended for fighting. It is possible that the ram was an Egyptian invention, and something of the sort is shown in action as early as 1200 B.C., but it was in Phoenician, Greek, and Roman galleys that its importance was most clearly emphasized.

With the ships and galleys of the Greeks firmer ground is reached, though there is still much that remains a subject of controversy. One thing seems certain—Greek vessels were built on a system entirely different from that of Egypt, having keel, stem, sternpost, and internal framing with the planks attached edge to edge on the sixth method mentioned above, practically the carvel building of modern times. In all probability the true Greeks, who were originally a race of nomadic shepherds, learned this from their predecessors in the Aegean, but how or where these first evolved so advanced a method of ship construction is still unknown.

2. Galleys.—The galley, an oar-propelled fighting vessel, is also included under the definition at the head of this article. At the time of the siege of Troy the normal large Greek rowing vessel seems to have been a 50-oared boat with a single row of 25 oars on each side, but suggestions could already be seen of still larger vessels, which must have had their oars arranged in some way which allowed more men to work in a given length, and it was this development which produced the bireme and began the process which led to the many-banked galleys of about 300 B.C.

Since galleys were always narrow, shallow craft, there was a very definite obstacle to increasing their length to any great extent because of the weakness of such a vessel against "hogging" or "sagging" strains tending to break it in half. Thus, the number

FIG. 1.—ANCIENT GREEK BIREME, A GALLEY WITH TWO BANKS OF OARS

of oars in a single simple row could not be increased very much and it became necessary to find some other method of getting greater power. It would seem the obvious course to put two or more men on each oar, but it was not until much later that the Mediterranean peoples did this. What was done was to arrange the oars in two staggered rows, the uppermost high enough to clear the heads of the lower rowers and their greater length allowing the upper rowers to sit far enough inboard for their legs to be clear of the ends of the lower oars. Another method was to have two oars quite close together at the same level with their two rowers sitting side by side, the foremost oar of a pair being the shorter. This plan was common in medieval times and was apparently employed to some extent in classical or postclassical times also, but it was from the first kind of bireme that the classical trireme and the later many-banked galleys were derived.

The Phoenician vessels of about 700 B.C. mentioned above were biremes of this type, and the trireme followed a little before 500. Its design is still to some extent a subject of dispute, but the view generally accepted is that its third set of rowers sat roughly above the lowest and at about the same level as the second, and that their oars worked on the outer edge of a long outrigger running almost the full length of the hull. This outrigger, once introduced, remained an almost invariable feature of the Mediterranean galley to the very last. Probably the trireme was invented in Greece or in one of the Greek colonies, and it was the Greeks of the last few centuries B.C. who produced the many-banked galleys which have still to be satisfactorily explained.

Galleys carried a mast and sail but were primarily rowing vessels, whereas the merchantman of Greece and Rome was a sailing ship pure and simple. It was much deeper and no doubt also much wider than the galley, without a ram and with stem and sternpost curving down to a comparatively short keel. Both ends rose well above the general level of the sides, but this was more pronounced at the stern, where the chief accommodation was situated. By Roman times, and probably before, the hull was what would now be called carvel-built, but one noticeable feature was that the ends of the deck beams usually projected through the side planking, as they had done in ancient Egypt.

The sail was what is called a square sail, set on a yard slung horizontally from the mast and carried more or less across the ship's fore-and-aft line. In early Egyptian vessels the mast had been like a narrow inverted V, but this had been replaced by a single stick long before classical times. At first there was only one mast and one sail, but by the beginning of the Christian era Mediterranean merchantmen had a second much smaller sail on a mast projecting over the bows, and could also set a triangular topsail or topsails above the maih yard. Some representations show the foresail a good deal larger and its mast more nearly upright, but the other arrangement was probably the more usual. The steering gear was inherited from Egypt, at least in principle, and consisted of a large paddle-shaped rudder on each quarter, held to the ship's side, but free to rotate on its axis and worked by a thwartship tiller. This side rudder, which was found in galleys as well, had obviously been evolved from a mere steering oar, free to move in any direction, and that step had been taken in Egypt before 1500 B.C.

II. MEDITERRANEAN AND NORTHERN VESSELS

1. Mediterranean Craft.—It will be convenient to take the story of Mediterranean sailing ships down to about A.D. 1300 before turning to parallel developments in the north. Actually, there was surprisingly little change in hulls, but there was a complete transformation in rig by the substitution of the lateen for the square sail. The lateen belongs to the family of fore-and-aft sails, carried so as to receive the wind on either side but to keep the same edge forward, whereas the square sail does just the reverse. The lateen is triangular in shape and is set on a long yard coming down nearly to the deck forward and rising well above the masthead at the other end. Evidence which came to light in 1955 showed that this sail was in use in the eastern Mediterranean at least as early as the 2nd century A.D. Where it was first used is uncertain, though the probabilities seem to point to Egypt or the Persian Gulf; in any case it is clear that the tide of Arab and Muslim conquest was mainly responsible for its spread. Even in modern times the area in which the lateen is the typical sail of local craft is much the same as that over which Muslim control once extended or threatened to extend.

The rig of a medieval lateener comprised two masts and two sails, the larger forward, and this rig was carried on a carvel-built hull with flush planking attached to a framework of keel, stem, sternpost and ribs. The deck beams still often projected through the side planking and the steering gear was still a semi-permanent oar-shaped rudder on either quarter. Except for an increase in the accommodation aft and a consequent widening and raising of the stern, the hull was similar to that of a Roman ship.

2. Northern Craft.—Northern vessels of the 13th century had developed on different lines from their southern rivals and had, as has been said, a much shorter history, but in their own way they were no less efficient, while in one respect—that of steering gear—they were superior. All evidence indicates that they had descended from simple dugouts, and many such craft have been unearthed in various countries; but it has not been possible to say with confidence that any of these are actually older than the first of the more advanced types that have been discovered, while early at-

FIG. 2.—LATEEN-RIGGED SHIP, FIRST USED ABOUT A.D. 100 IN THE EASTERN MEDITERRANEAN AREA

tempts at depicting northern vessels are too crude to show much.

The earliest-known specimen of an actual northern boat is believed to date from about 300 B.C. and was found in Als, Den., in 1921. Its dugout ancestry is clearly shown by the way in which its two ends are carved from solid blocks, but between them it is formed of five planks overlapping in clinker-built fashion and sewed together. These planks, which must have been worked with an adze, have projecting cleats left on the inside at intervals of rather more than three feet and bent timbers are tied to holes in these cleats and kept in shape by passing through slots at the ends of the thwarts and in another series of transverse timbers beneath them. This boat is about 45 ft. (14 m.) long.

The remains of two vessels discovered at North Ferriby in Yorkshire in 1937 show a different form of development from the primitive dugout, or perhaps from the raft. In their case there is a flat bottom formed from three planks curving upward at the end with the side planks curving round to meet it. The planks are much heavier than those of the Als boat and are fitted edge to edge with a sort of rudimentary tongue-and-groove joint; they also are sewed together and have internal battens covering the seams. The bottom planks have internal cleats, but the short, straight transverse timbers run through holes in these instead of being lashed to them; how the side planking was supported is uncertain. The date of this find is believed, on geological evidence, to lie somewhere between 200 B.C. and A.D. 100.

As far as can be judged, this type of construction was a dead end, perhaps merely local; certainly later developments in northern Europe followed more on the lines of the Nydam boat, found near Flensburg in Schleswig in 1863. In this 75-ft. (23-m.) vessel, dating from about A.D. 250 or a little later, one of the chief problems of the primitive shipbuilder, the treatment of the ends, was solved by the use of an almost modern-looking stem and sternpost, though there is still no true keel but only a centre plank rather heavier than the others. The planks, too, are nailed together in modern clinker-built fashion, but the ribs—cut to shape instead of bent—are still lashed to cleats on their inside. This vessel shows another feature which remained characteristic of northern ships for almost another 1,000 years, the single side rudder on the starboard (steer-board) quarter.

The remains, or rather the traces, of a similar, rather larger boat dating from the early part of the 7th century were found at Sutton Hoo in Suffolk in 1939. Many objects of great interest were found in the excavation, but the actual wood of the boat had entirely disappeared, though changes in the sand where it had lain made it possible to determine the vessel's shape and even details of its construction, which was almost the same as that of the Nydam boat.

Both these last two boats were purely rowing craft, but those unearthed at Gokstad and Oseberg in Norway in 1880 and 1903 were definitely sailing ships, though still using oars as well. They date from about A.D. 900 and 800, respectively, and are built on much the same system as that from Nydam, clinker-built with ribs lashed to cleats and double ended, with the stern almost exactly similar to the bow. Each carried a single square sail as did the larger Viking ships. The Vikings' fighting ships, or longships, for short voyages in comparatively sheltered waters, were shallow, narrow in the beam, and pointed at both ends, and were thus maneuverable with oars in creeks and bays. Probably the largest had but ten oars to a side. It seems likely that a ship's complement would contain twice as many men for fighting as for rowing; therefore, a 20-oared vessel would carry 60 men. The warriors' round and painted shields hung outside along the bulwarks, and the vessel was steered by an oar at the starboard side. Prow and stern rose high, the former being carved, most often as a snake's or dragon's head.

The Viking *hafskip*, for the carriage of families and goods over open sea in summer, sometimes was more than 70 ft. (21 m.) long and up to 20 ft. (6 m.) wide. Relying more on its large square sail (suspended from a 40-ft. mast) than on its oars, it had fewer rowers than the longship. It was steered by a rudder on the starboard quarter; had two boats, one on board, the other in tow; and could be covered with awnings. On the voyages of colonization

FIG. 3.—LONG SHIP OF THE TYPE USED BY WILLIAM THE CONQUEROR, AS SHOWN IN THE BAYEUX TAPESTRY

such a ship would carry wives, children and livestock, stores, and at least 30 men. A 19th-century replica of the Gokstad ship made a successful Atlantic crossing in 27 days.

This double-ended type of ship remained in use for several centuries, but the method of lashing the ribs to cleats was superseded by nailing, and the keel plank was replaced by a true keel. This stage had been reached by the boats found in 1933–34 at Ohra near Danzig and believed to date from about 1000; the abandonment of internal cleats was perhaps due to the use of saws instead of adzes for shaping the planks.

The ships used by William I in 1066 (shown in the well-known Bayeux tapestry) had probably reached the same state of development. Some of them have their masts supported by shrouds, and this suggests that by the time the tapestry was made—probably not earlier than 1150—northern ships were able to sail with the wind at least abeam. Roman ships had used shrouds centuries before, but this is their first appearance in the north; after this they are almost invariably shown in ships on seals and elsewhere.

From such evidence it can be said that there was little change during the 12th century apart from the fitting of light "castles" at either end of the larger vessels; but at the end of that period came one of the great steps in the history of sailing ships, the introduction of the stern rudder. When or where this first appeared is uncertain, but the date cannot have been far from 1200 and the place was probably the Netherlands or thereabouts. The step was important, not only for the increased efficiency it gave, but also for the fact that it was followed—almost necessarily—by a differentiation between bow and stern and the transformation of the double-ended northern ship into something far more like its contemporaries in the Mediterranean. When about 1300 the nations of southern Europe recognized the superiority of the new type and adopted both the stern rudder and the square sail, a standard European ship was not far off, though there was still the distinction between the clinker-built northerner and the carvel-built southerner. *See* also RUDDER.

III. MEDIEVAL SHIPS

With the invention of gunpowder and the first use of guns on board ship soon after 1350 there began a process which caused the sailing man-of-war to become more and more distinct from the merchantman. Otherwise the 14th century brought little change, but developments in the 15th more than made up for this. In 1400 ships still had one mast and one sail; before 1450 some of them had three masts and three sails; by the end of the century the largest had four masts and eight sails. Meanwhile, carvel building had spread from the Mediterranean to the north and the ships of all Europe had become similar in both hull and rig, though there were still national or even local variations of type.

In view of the great importance of this short period it must be treated in some detail. The change from one mast to three was very rapid, but was not accomplished in a single step; there was an intermediate two-masted stage, at least in some instances. In inventories of the ships of the Royal Navy in 1410–12 may be

found one ship, and only one, with "1 mast magn" and "1 mast parv"—one big mast and one small. Whether this second mast was before or abaft the mainmast is still only a matter of opinion, but the ship in which it was carried was apparently southern in origin and thus more likely, because of its lateen-rigged ancestry, to have had its smaller mast aft rather than forward. In any case, the two-masted stage was so brief that by 1435 or thereabouts the third mast had come to stay.

One at least of the ships in these inventories of the early 15th century was surprisingly large. Henry V had a ship under construction at Bayonne in 1419 that measured 112 ft. (34 m.) on the keel, 186 ft. (57 m.) from stem to sternpost and 46 ft. (14 m.) in beam. This ship was never finished, but the "Grace Dieu," built at Southampton in 1418, was even larger. Investigation of its remains, resting in the mud of the neighbouring Hamble River, in 1933 established the fact that its keel was more than 125 ft. (38 m.) long and its beam probably not far short of 50 ft. (15 m.); also it was clinker-built, as would be expected, but each strake was made up of three thicknesses. Such a method of construction had not previously been suspected, but a later study of accounts for building a number of so-called galleys in England in 1295 suggested

FIG. 4.—THE CARAVEL "NINA," ONE OF THE SHIPS USED ON COLUMBUS' VOYAGE TO AMERICA

that these were of two-layer clinker work and the same may well have been the case in many of the larger vessels of the 14th and 15th centuries.

It is probable that the "Grace Dieu" had three masts, though neither the foremast nor the mizzen would have been of much size or at all elaborately rigged. The foresail would undoubtedly have been a square sail, but the mizzen is more likely to have been a lateen; certainly it became the rule within the next few years for the third mast (and afterward the fourth) to carry a sail of that kind. This was one of the two essentially southern features of the newly developed full-rigged ship; the other, carvel building with flush-fitting planks attached to frames previously erected, reached the north a little later. It may be that it had been used on the west coast of France as long ago as the time of Julius Caesar, who fought a naval battle on the Loire in 56 B.C. and described the ships of his opponents, the Veneti, in some detail without suggesting that their construction was in any way radically different from that of Mediterranean ships. In any case, Brittany seems now to have been the centre from which the new method of building began to spread, but it was soon almost universal for large ships, whether men-of-war or merchantmen.

Toward the end of the 15th century ships of moderate size had three masts and five sails: main, fore, mizzen, main topsail, and the spritsail under the bowsprit; these were, for instance, the sails carried by Columbus' "Santa Maria" in 1492. Considering that bowsprits had been present for more than 200 years, the spritsail was surprisingly late in appearing, as it did, at about the same time as the main topsail in the third quarter of the 15th century.

The original function of the bowsprit is somewhat doubtful; it has usually been supposed that it was to give a better lead for the bowlines, which controlled the windward edge of the mainsail, and it is certain that it was afterward used for a similar purpose, but there is much to be said for a suggestion that the first bowsprits were used in connection with the anchors.

Besides the sails just mentioned, the largest and most elaborately rigged ships of about 1500 would carry a fore-topsail, a main topgallant sail above the topsail, and perhaps a lateen topsail above one or both of the two lateen mizzens, the aftermost of which was usually called the bonaventure. They were still armed for the most part with a great number of small guns disposed in the towering structures which had grown from the two castles of the 13th century, but the time had almost come for larger guns to be carried and for them to be mounted between decks and to fire through openings in the main hull, as they did until the last days of sailing men-of-war and even later. The invention of these gun ports is traditionally ascribed to a French shipbuilder in 1501, and the date, at least, is approximately correct.

1. Caravel and Galleon.—Another change came about now in the shape of the stern. Starting from the pointed shape produced by giving the double-ended ship a straight sternpost, to carry the rudder, the stern had gradually had its upper part widened more and more by means of a transverse timber, the transom, on which the aftercastle was based, and as a result the lines of the stern had become fuller and fuller, until the shape of its lower part was not far from being a quarter of a sphere. In the new form, which probably originated in the south and in a comparatively small type of vessel, the caravel, the attempt to make the planking conform to the required shape was abandoned and the stern from a little below the water line to the transom was given a flat finish, while the lines below this were made much finer.

The true caravel was a lateen-rigged vessel with three masts, the largest forward. Being a southerner it was carvel-built and it is more than likely that the two words were connected. In any event, they soon became hopelessly confused. The "Santa Maria" is often said to have been a caravel, but this is incorrect, though its two companions were caravels, at least in the shape of their hulls.

Then came the galleon, in which the general principles of the design of sailing men-of-war were finally established. As the name implies, it had something of the galley about it, though it was still purely a sailing ship. The Mediterranean galley had retained the ram of its classical predecessor, but had raised it from the water line and lengthened it into a long beak, and this feature with a square-ended forecastle rising abaft it was incorporated in the galleon in place of the triangular overhanging forecastle of the previous carrack type. At the same time, the hull was made longer, so that the keel became about three times the beam instead of two and a half times or less, while the number of heavy guns between decks was increased until they ran in one or two tiers for the full length of the broadside. This last change was well shown when the famous "Henry Grace à Dieu" of 1514 was rebuilt in 1536, though in shape it remained a carrack rather than a galleon, as did most other large northern ships for another 40 years or more.

2. Notable Ships.—Competition among various countries in the first half of the 16th century produced a number of outstanding ships such as the Scottish "Great Michael," the English "Henry Grace à Dieu" (or "Great Harry"), the Portuguese "São João" and others, but none of these was as large as the "Grace Dieu" of

1418 and after their time there came a reaction. The biggest ship of Elizabeth I's reign, the "Triumph" of 1561, was only 100 ft. (30 m.) on the keel and 40 ft. (12 m.) in beam, while a Portuguese vessel captured in 1592 and then believed to be the largest ship in the world was about 25 ft. shorter and 3 ft. narrower than the "Grace Dieu" of nearly 200 years before.

Some idea of the size of merchantmen at this time can be obtained from the list of the fleet which met the Spanish Armada in 1588. The largest of the privately owned vessels was of 400 tons, the smallest 20. Of these some of the larger were really private men-of-war built as such, while the smaller were mere coasters of no fighting value. The average tonnage of the 30 ships equipped by the city of London was 150, which would correspond to a keel length of 60 ft. (18 m.) at the most.

By this time, however, the opening of the sea route to India had led to the building of large state-owned merchantmen in Portugal, the ship just mentioned being one of these, and when the English and Dutch began at the opening of the 17th century to force their way into the same waters, they too began to use larger merchantmen: indeed, the Netherlands East Indiamen were larger than any man-of-war.

IV. 17TH AND 18TH CENTURIES

The first half of the 17th century saw the culmination of the galleon type in the "Prince Royal" of 1610, the "Sovereign of the Seas" of 1637, and its French contemporary, the "Couronne." The two English ships were three-deckers and the "Sovereign" was the first ship to carry what was for nearly a century the standard armament of a first rate, 100 guns. The "Couronne," though of almost the same size as the "Sovereign," was a two-decker of 72 guns, an early example of the French tendency to build ships very large for their armaments. The same period also saw certain noticeable changes in sail plan. The fourth mast (the bonaventure or after mizzen) disappeared, the lateen mizzen topsail was replaced by a square sail, the spritsail topmast appeared, standing upright on the end of the bowsprit, and royals above the topgallants became possible, though probably seldom set.

1. The Frigate.—Then came the frigate, not the well-known type of Nelson's day but its 17th-century namesake. Originally the *fregata* was a small member of the galley family used in the Mediterranean chiefly as a dispatch boat. The name was then applied by the Spaniards to the small fast vessels used to bring treasure from America and from them passed to the ships of the semipiratical privateers of Dunkirk, from which the first English frigates were copied. The exact essentials of such a frigate are by no means clear, but they certainly included an increase in length (or a decrease in beam) and a reduction in top hamper. Soon, however, the name ceased to mean much more than a ship of modern design, since even three-deckers were occasionally called frigates, at least in England.

The chief reason for the growth of the frigate was no doubt the fact that the second half of the 17th century was a time of frequent naval fighting between well-matched opponents and of many hard-fought actions between enormous fleets. Experience soon showed that ships armed almost solely on the broadside should fight in line ahead in a prearranged order, and this in its turn led to the conclusion that the ships in such a line must be of a certain minimum strength, 40 guns or more. Such was the origin of the term ship of the line or line-of-battle ship—abbreviated later to battleship.

2. Improvements in Rigging and Equipment.—Just before the appearance of the 17th-century frigate, sometime about 1630, English shipbuilders had made a change in the shape of the stern by rounding off the sudden turn between the side planking and the flat stern of the galleon type sufficiently to admit of working the planking round to the sternpost and transom while maintaining the fine lines below water. Although the flat stern continued to occur at intervals almost to the last days of sailing men-of-war, especially in the smaller vessels, the new form of stern was more or less a distinguishing feature of English ships for at least 50 years; it was not imitated by other countries until the end of the 17th century or the beginning of the 18th.

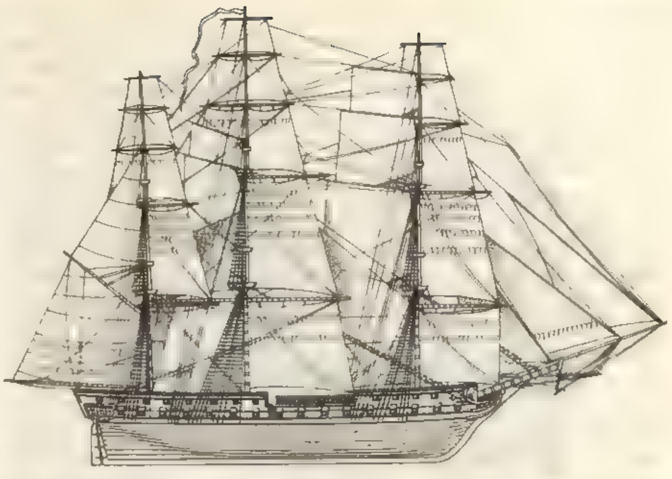

FIG. 5.—U.S. FRIGATE "PRESIDENT," LAUNCHED IN 1800

By then the French Navy had become important, not only because of its great expansion under Jean Baptiste Colbert, but also because of the quality of its ships. This was not merely a matter of increased dimensions; another reason was the greater attention paid in France to the scientific side of naval architecture. Because of these two factors the French, and at a later date the Spaniards, built ships more efficient, class for class, than any produced in England. The first half of the 18th century was, indeed, a period of comparative stagnation in English shipbuilding, at least as far as men-of-war were concerned. It was the period of "establishments" laying down standard dimensions for ships of each class and thus cramping the initiative of the various builders. Each successive establishment certainly allowed some increase in size, but this was never enough to overtake what was being done on the continent.

The chief interest of the period lies in its developments in rig and equipment. Staysails had been in use for 50 years or more, and there were already such sails on the three stays leading to the bowsprit, but in 1700 or thereabouts a new sail of the same kind—the jib—was introduced, carried between the fore-topmast head and the jib boom, which was a small spar fitted as a prolongation of the bowsprit. Obviously this sail demanded the removal of the spritsail topmast, but an attempt was made for at least another 25 years to carry both together; then the spritsail topmast vanished and its sail was shifted to beneath the jib boom. The bobstay, to hold down the bowsprit, seems to have come just before the jib. Why it should have taken so long to produce so apparently essential a piece of rigging is hard to say, but no trace of a bobstay earlier than 1690 has yet been found. Bowsprit shrouds came a little later. At the other end of the ship the part of the lateen mizzen before the mast was done away with and, though the biggest ships kept the whole yard for a long time, it was gradually replaced by a gaff such as was carried in the 19th century; by 1800 the long mizzen yard was a thing of the past.

The introduction of the steering wheel was a less conspicuous but extremely important change. From the middle of the 16th century to the end of the 17th the tiller had been worked by means of the whipstaff, a vertical lever acting on its inboard end and passing through a pivot in the deck above, a device which must have been much less efficient than the wheel with its ropes leading to the end of the tiller. In England the wheel was first used about 1705; there is a suggestion that something of the sort may have been tried in France somewhat earlier, but other countries seem to have waited a few years before adopting it.

By 1750 the smallest ships considered fit for the line of battle carried 64 or 60 guns, though there were still smaller two-deckers of 50 and even 40 guns. After them came the 24-gun ships, which were really small two-deckers with only four ports on the lower deck, and it was these which developed into the frigates of Nelson's time, where the lower deck, though still called in England the gun deck, carried no guns at all. The first of these new-type frigates were built in England in 1756 and in France a few years

FIG. 6.—ADMIRAL NELSON'S FLAGSHIP, THE BRITISH SHIP OF THE LINE "VICTORY"

sooner; they carried 28, 32 or 36 guns, but soon grew, until the largest of them actually mounted as many as 56 guns, though classed, because of the peculiarities of official rating, as 44s. One of these heavy frigates, the USS "Constitution" of 1797, has been more or less restored to its appearance in the War of 1812; while in England the 100-gun "Victory," built in 1765, is preserved in drydock as it was at Trafalgar in 1805.

At the time of its launching the "Victory" was the largest British ship afloat, but even so it was hardly larger than the "Grace Dieu" of 1418 and no English (or British) ship in the meantime had been as large. It was 186 ft. (57 m.) on the gun deck and 52 ft. (16 m.) in beam, whereas its Spanish contemporary, the "Santissima Trinidad," measured 204 ft. by 53 ft. and the French "Commerce de Marseille" of 1790 was 208 ft. by 54 ft. Before the end of sailing men-of-war the beam of the largest ships had risen to as much as 60 ft.; but the length never went beyond the 210 ft. of the USS "Pennsylvania" of 1837, and about 205 ft. was usually the maximum. The reason for this was the tendency of long wooden ships with guns all along the broadside to "hog" or drop at the ends. Merchantmen did not present quite the same difficulty and in their case with improved methods of construction it proved possible to make the length much greater.

V. THE 19TH CENTURY

In merchantmen the increase of length, both actually and in relation to the beam, was associated with the rise and development of the clipper ship in the middle of the 19th century. At the time of the Napoleonic Wars the largest and finest merchantmen afloat were those in the service of the East India Company, heavily built vessels not unlike men-of-war and actually used as such on occasion. The largest of them, the 1,200-ton class, measured about 165 ft. (50 m.) by 42 ft. (13 m.). With the ending of the company's monopoly of trade with the East in 1833, the various owners who had supplied it with ships began trading on their own account and were at once driven by mutual competition to employ ships of greater efficiency as speedy carriers of cargo. The first of these were comparatively small, but by 1842 they were back at 1,200 tons with the "Prince of Wales" measuring 179 ft. by 39 ft., much longer and at the same time narrower than the older type.

1. Clipper Ships.—By then the clipper was coming to the fore. It is a matter of controversy which was the first clipper ship and what were the essential characteristics dividing it from its predecessors, but on the whole the U.S. "Ann McKim" of 1833 seems to have the best claim to the title. In any case, it was a matter of gradual evolution rather than sudden change, since this ship was little more than a slightly enlarged version of the existing Baltimore clipper type, well-known as successful privateers and slavers. Other claimants are the British "Glentanar" of 1842, developed from the schooner "Scottish Maid" of 1839, and the U.S. "Rainbow" of 1845. In the case of the "Scottish Maid" and its Aberdeen-built successors, it is possible that the most obviously revolutionary feature of the design, the long overhanging bow, was primarily a means of cheating the existing rule for measuring tonnage and that the increased speed it gave was to some extent a by-product. However this may be, clippers, in the strictest sense of that ill-defined and very elastic term, were being built in ever-increasing numbers on both sides of the Atlantic by the end of the 1840s.

They were chiefly employed in the tea trade from China, in carrying passengers from the eastern part of the U.S. to San Francisco after the discovery of gold in California in 1848, in similar voyages from Great Britain to Australia a few years later, and finally in the Australian wool trade. On the whole, the U.S. clippers were larger and more powerful ships than the British and therefore capable of greater maximum speeds, but in the matter of all-round performance there was little to choose between the two types. The American "Lightning" of 1854 is believed to have made the best day's run ever recorded by a sailing ship, 436 mi., but the palm for consistently fast passages in all conditions should probably be given to two of the last British tea clippers, the "Thermopylae" and "Cutty Sark" of 1868–69.

Apart from their finer lines as compared with ships of an older

FROM BJORN LANDSTROM, "THE SHIP," ILLUSTRATION COPYRIGHT 1961 BY BJORN LANDSTROM; REPRODUCED BY PERMISSION OF DOUBLEDAY & COMPANY, INC.

FIG. 7.—BRITISH CLIPPER SHIP "CUTTY SARK"

type and the relatively greater spread of canvas which they carried, the clippers owed much of their speed to a further increase in length as compared with beam. The process had, as has been said, begun with the first successors of the old East Indiamen, but was taken much further in the clippers. The "Rainbow" had a length about 4 times its beam, as had been the rule toward the beginning of the century, but in the "Lightning" the ratio reached 5.6. British builders went in for ships still longer and narrower; the usual standard, from the "Stornoway," built three years before the "Lightning," to the "Cutty Sark," was a length of about six times the beam, and this was sometimes exceeded, as in the "Lord of the Isles" of 1853 with 6.4 and the "Queensberry" of 1856 with the extreme figure of 7.2. This increase of length was to a great extent made possible by the advent of steam, which allowed these comparatively unhandy ships to be towed in and out of harbour.

Meanwhile, there had been many improvements in construction and rig. Even with new methods of framing introduced soon after the beginning of the 19th century it was still difficult to build wooden ships beyond a certain length. The use of iron did away with this difficulty and the "Lord of the Isles" was an iron ship, but this was found to be bad for a tea cargo and a compromise was effected by means of the composite method of building with wooden planking on iron frames. In the matter of equipment the great step was the introduction of wire in place of hemp for standing rigging in the early 1850s, soon followed by the invention of the double-topsail rig, which, though perhaps no more efficient, was much easier to handle than the large single sails previously carried.

2. Last of the Sailing Ships.—By the time these changes took place, the sailing man-of-war was rapidly becoming more and more obsolete. There had been paddle steamers in the British fleet from 1822 and some of the last of these had been ships of considerable importance, but it was not until the adoption of the screw in the 1840s that it became possible to combine steam propulsion with the complete broadside armament of the larger classes. When once this stage had been reached, ship after ship was given engines of steadily increasing power, till by 1850 no more purely sailing men-of-war were being built. Masts and sails were retained for a long time, but gradually the two systems of propulsion exchanged roles, and the man-of-war, instead of being a sailing ship with an auxiliary engine, became a steamship with auxiliary sail.

In the case of merchantmen the distinction between steamships and sailing ships was made much sooner and more definitely. It is true that unsuccessful attempts to give deepwater sailing ships auxiliary steam power were made before 1840 and that steamers, especially those employed on long voyages, continued to have masts and sails, though they seldom had anything like full ship rig; but on the whole the sailing merchantman was one thing and the steamship another almost from the first.

In one trade after another, particularly those where perishable cargoes had to be carried, steamers began to take the place of sailing ships. The opening of the Suez Canal in 1869 was a heavy blow to the sailing ship, since, besides shortening the route to the East, it reduced the distance between coaling stations and so allowed steamers to devote more space to cargo. After this the surviving China clippers turned for the most part to the Australian wool trade and it was in this that such ships as the "Thermopylae" and "Cutty Sark" made their reputations. Then came grain from Australia and nitrate from the west coast of South America, till at length the Panama Canal, opened in 1914, gave steamers the advantage even there.

For nearly 250 years the standard rig of men-of-war and of the larger ocean-going merchantmen had been that of the full-rigged ship with three masts all carrying square sails. When the square mizzen topsail was first introduced, the long yard of the lateen mizzen beneath it had made it impossible to carry a square course or lower sail; the yard spreading the foot of the topsail, the "crojack" in English, was in fact called in French the *vergue sèche* or "barren yard," because it set no sail of its own. The square mizzen course did not appear until about 50 years later, in the middle of the 19th century.

Meanwhile, many smaller vessels, in particular the collier barks of the North Sea, had carried no square sails on their mizzenmasts. It is probable that originally the term bark marked a distinction in size and in form of hull rather than in rig; but when large ships began once more to do without square sails on the mizzenmast, they were called barks or barques, the French form of the word being for some reason usually preferred. This became the fashion soon after the clipper ship era, when it was necessary for sailing ships to reduce their crews, and thus their running costs, to meet the competition of steam.

At the same time the need for greater cargo-carrying capacity produced ships both larger and fuller bodied, though the increased length and power did a good deal to compensate for the loss of the finer lines of the clippers. Composite building had only a short life, and iron (and afterward steel) ships became the rule; while with the increase of length it was found desirable to add a fourth mast, the result being the four-masted ship or four-masted barque, according to the rig of the aftermost or jigger mast. Four-masted square-rigged vessels had been almost unknown since about 1630, but not entirely so; the French privateer "L'Invention" of 1801 had been a four-masted ship in the strictest sense of the term, while the famous "Great Republic" of 1853, the largest of the U.S. clippers, 325 ft. (99 m.) long, had been a four-masted barque. On the whole, the barque rig proved the more satisfactory and at the beginning of the 20th century the four-masted barque could be considered the standard type, though there were some noteworthy exceptions.

For the most part this final development of the sailing merchantman was in the hands of British, French, and German builders. In the U.S., which had taken so conspicuous a place in the days of the clippers, the building of square-rigged vessels declined rapidly after 1860; but as some compensation for this there came a boom in large fore-and-aft rigged vessels, the original two-masted schooner of the 18th century becoming by degrees three-masted, four-masted, and even six- and seven-masted, the climax being reached in the "Thomas W. Lawson" of 1902. At the same time, many square-rigged vessels bought from foreign owners were rerigged as many-masted schooners.

French shipowners had the benefit of a system of bounties which are said to have been high enough to allow sending a ship round the world in ballast, without cargo, and still making a profit on the voyage, the result being that some very large ships were to be found under the French flag toward the end of the sailing-ship era.

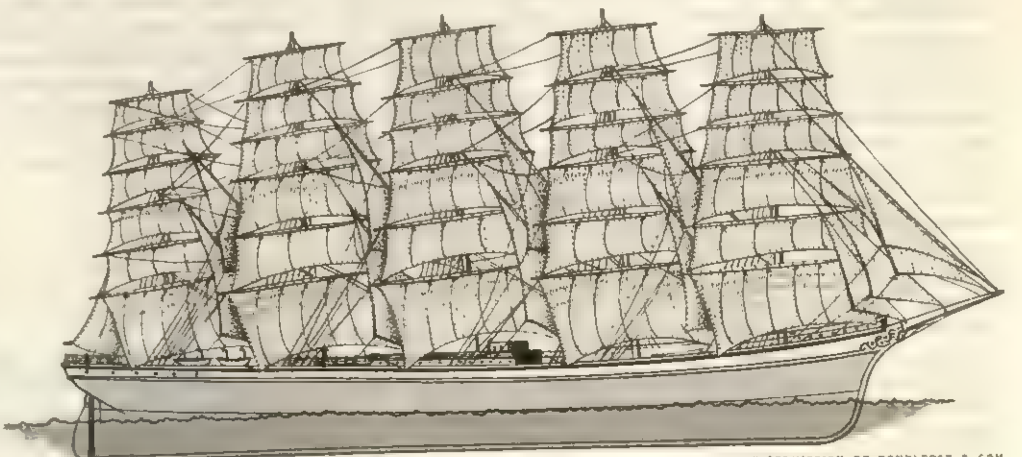

FIG. 8.—"PREUSSEN," ONLY FIVE-MASTED, FULL-RIGGED SHIP EVER BUILT

The five-masted barque "France" of 1890, with a length of 361 ft. (110 m.), was built in Scotland, but the next ship of the name, the largest sailing ship ever built, was launched at Bordeaux in 1911. It, too, was a five-masted barque and was 418 ft. (127 m.) long with a gross tonnage of 5,633. This ship was wrecked in 1922; its predecessor had been lost at sea in 1901.

In the same way the first of the German five-masters, the "Maria Rickmers," was built in Scotland in 1890 and was of about the same size as the first "France"; but the "Potosi" (1895), "Preussen" (1902) and "R. C. Rickmers" (1906) were all built in Germany and each was larger than the one before, the last being 410 ft. long and measuring 5,548 tons. All save the "Preussen" were rigged as barques.

World War I caused the loss of many sailing ships and it was no longer financially practicable to replace them. The Germans built a few curious five-masted vessels with auxiliary motors, rigged as schooners with square topsails on the first and third masts; while the Danish East Asiatic Company had a large auxiliary five-masted barque, the "København," built in Scotland in 1921, but this was intended primarily for a training ship. It, too, was unfortunate, being lost at sea in 1929. Meanwhile, the survivors of the days of sail were lost or laid up, until in 1929 the last British square-rigged sailing ship left in service was also lost; this was the "Garthpool," built as the "Juteopolis" in 1891. A few, mainly German in origin, passed into Finnish ownership and except for a break caused by World War II continued to bring grain from Australia as late as 1949. In 1950 the last two of these were for sale. The only large square-rigged sailing ships still in service in the 1960s were those used by several countries as training vessels for their naval cadets. (Rr. C. An.)

VI. INTRODUCTION OF STEAM AND IRON

A revolution in the history of the ship may be said to have occurred with the changes from sails to steam engines for propulsion and from wood to iron for construction. These proceeded together, but at first slowly. There was still much ignorance of the principle of flotation by displacement, and it was urged by the unenlightened that iron would not float and was therefore unsuitable for ship construction. Even among those who realized the fallacy of this argument it was asserted that an iron ship would be far more easily damaged in the event of her touching the ground than a wooden one, while there existed the real difficulties of preserving the bottom from the action of the sea and fouling by weeds and barnacles, and of compensating the compass for the errors produced by local attraction. With regard to the strength of the ship, experience showed that iron construction was better able to withstand rough usage than was wood, and examples, such as the "Garry Owen" in 1834, were not lacking of iron and wooden ships being stranded together by the same gale and under similar circumstances and the iron ship getting off little the worse, while the wooden ship became a total wreck. Another remarkable instance of the endurance of iron ships was that of the "Great Britain," which, in 1846, ran ashore in Dundrum Bay in Ireland and settled on two detached rocks; it remained aground for 11 months, was subsequently got off, and afterward did good service. In due course a suitable composition was discovered for painting the underwater surface of iron ships, while trials carried out in the "Rainbow" at Deptford and the "Ironsides" at Liverpool went far toward providing the solution for correcting the compass.

One of the earliest iron craft on record was a boat apparently intended for passenger service, built on the banks of the Foss River in Yorkshire in 1777. In 1787 a canal lighter was constructed with a shell of iron plates, and for many years iron and wood were used in conjunction for the construction of what were known as composite ships.

For warships iron was at first objected to because it was thought that the enemy's shot would cause more serious damage to them than it would to a wooden ship, but this again was proved to be a fallacy. The first iron steamer was the "Aaron Manby," built at Horsley in 1821 and assembled in London.

1. The First Steamboats.—One of the earliest proposals for a steam-driven boat was made in 1690 by Denis Papin. In 1707 he built a paddle boat and tried it on the Fulda, but the paddle wheels were turned by man power, not by steam. In 1736 Jonathan Hulls, of Gloucestershire, patented a steam tugboat, but it was never tried. The first experimental steamboat to be built, in France, by Comte J. B. d'Auxiron in 1774, foundered before it could be tried. In 1775, however, Jacques C. Périer contrived, for the first time in history, to move a small boat by steam power on the Seine at Paris. After unsuccessful experiments with a 43-ft. steamboat and palmipede or "duck-foot" paddles, on the Doubs in 1778, the Marquis Claude de Jouffroy d'Abbans built his "Pyroscaphe" of 182-tons displacement, fitted with a double-ratchet mechanism to produce continuous rotation of the paddle wheels. In 1783 this vessel, the first really successful steamboat, mounted the Saône River near Lyons. In 1787 James Rumsey drove a boat on the Potomac four miles an hour by means of a power pump. About the same time John Fitch produced his oar-driven steamboats.

A more practicable device was to be the paddle wheel. The "Charlotte Dundas," constructed by William Symington in Scotland in 1802, was one of the earliest of these vessels. It proved its utility for towing work on the Forth and Clyde Canal. Robert Fulton, having witnessed the success of this craft, in 1807 constructed the "Clermont" on the Hudson River in the U.S. The engines for the vessel were made by Boulton and Watt in England. It proved popular as a passenger boat between New York and Albany. The first steamer to make a regular sea voyage was the "Phoenix" which, in 1809, steamed from Hoboken, N.J., to Philadelphia, Pa. In 1812 Henry Bell built his steamer "Comet," which carried passengers between Glasgow, Greenock and Helensburgh. It was 43 ft. long, 11 ft. broad and 5½ ft. deep and was driven by a one-cylinder engine. The success of these early steamers soon produced others. In 1815 the "Margery" of 38 tons, constructed on the Clyde, was brought through the Forth and Clyde Canal and then down the east coast to the Thames. In 1816 this same vessel, renamed the "Elise," was the first steamer to cross the channel to France.

In Great Britain the steamship was first used only as a passenger carrier and tug along rivers and canals, but gradually increased competition forced the shipowners to seek other spheres and in doing so they found that steamers could perform short coasting voyages. The steamship then became a passenger carrier along the coast to the various holiday resorts, its novelty being the principal attraction. The owners soon realized that the steamship was capable of much more than this and vessels were built to cross the North Sea, the Straits of Dover, and the Irish Sea. They were modeled on the sailing ships that they replaced and all carried auxiliary sail either on masts or on their funnels, as the low-pressure machinery was wasteful and incapable of giving any considerable speed. The various methods of propulsion which had been experimented with in the 18th and early 19th century, including a rudimentary screw propeller and jet propulsion, gave way to the side paddle wheel, which remained in favour for many years.

2. Atlantic Crossing.—It was not long before steamship owners aspired to cross the Atlantic by steam. The sailing packet "Savannah," which had been designed to run on the service between New York and Le Havre, was given auxiliary steam machinery and crossed the Atlantic from Savannah, Ga., in May and June 1819. It only used its engines for about 85 hours of the voyage, but

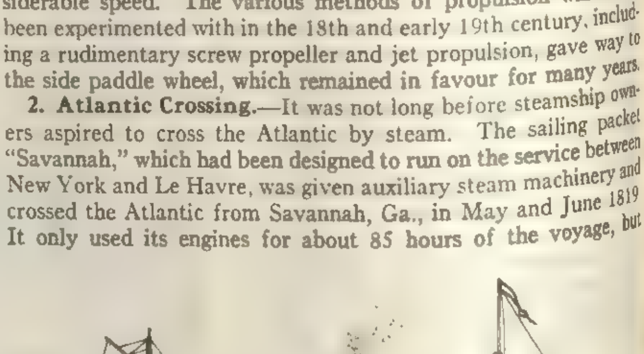

FIG. 9.—ROBERT FULTON'S "CLERMONT"

arrived off Ireland with its coal consumed. Afterward the "Savannah" visited the Baltic, where it aroused great interest. Although this is generally recorded as the first steam Atlantic crossing, the vessel returned to the U.S. under sail alone. The first to use steam power on the Atlantic in a westerly direction was the "Rising Star" of 428 tons, built at Rotherhithe in 1821 for Thomas Cochrane, earl of Dundonald. It had internal paddle wheels, and in 1821–22 crossed from Gravesend to Valparaiso, Chile. In 1824–25 the "Caroline," first steamer in the French Navy, crossed from Brest, France, to Cayenne, French Guiana.

The steamer "Curaçao," built at Dover in 1825, a wooden paddler of 438 tons, was purchased by the Dutch government as a man-of-war but was employed on the mail service to the Dutch West Indian colonies. It left Rotterdam on its first passage to the West Indies in April 1827 and took 28 days to do the voyage, after which it made the regular sailing each year, until it was required as a warship during the troubles in Belgium in 1830, after which it never returned to the mail service.

The first transatlantic steamer of the Royal Navy was the "Rhadamanthus" of 813 tons, which crossed from Plymouth to Barbados in 1832. The next steamer to perform the feat was the "Royal William," whose performance was particularly remarkable because of the fact that it was built in Quebec with the idea of running from that port to Halifax. Samuel Cunard, who afterward founded the great Atlantic company, was one of its owners. Trade depression and an epidemic of cholera spoiled its chances in the trade for which it was designed and it did no better as a tug. Its owners, being forced to consider its sale and thinking that they would get a better price for it in Europe than in Canada, sent it across the Atlantic in 1833. It took 25 days to do the passage and burned 324 tons of coal. Afterward it was sold for £10,000 and later served in the Portuguese Navy as a transport and in the Spanish Navy as a warship until it was finally condemned in 1840.

3. Regular Atlantic Passages.—These early steamship passages across the Atlantic were more or less haphazard, but it soon became the object of the owners to provide a regular service. Pending the construction of suitable tonnage the 703-ton steamer "Sirius," which had been built for the Irish Sea service, was chartered in 1838 by the British and American Steam Navigation Company. It was considered a big steamship in its day and was one of the first steamers to be fitted with a surface condenser, patented by Samuel Hall in 1834, instead of using salt water in its boilers; this represented one of the milestones of steam engineering at sea. It sailed from London to New York by way of Cork with 40 passengers and although it was grossly overloaded to modern ideas it made the passage in safety. Within a few hours of its arrival in New York a very much bigger and finer steamer, the "Great Western," which had been constructed with the idea of continuing the Great Western Railway across the Atlantic, arrived after a crossing of 15 days from Bristol. It had a tonnage of 1,320 and was regarded as the finest steamship of its day.

After this several other Atlantic liners were built but all the services were irregular and maintained by a heterogeneous collection of ships, suitable and unsuitable. It was when Samuel Cunard founded his transatlantic line in 1840 that a new policy in shipping produced a revolution in shipbuilding—the construction of sister ships. He started operations with four transatlantic ships and one small feeding steamer, the "Unicorn," in Canadian waters.

The sister ships "Britannia," "Acadia," "Columbia" and "Caledonia" were wooden steamers built on the Clyde, their tonnage according to the rule then in use being about 1,150 on dimensions 207 ft. by 34 ft. 2 in. by 22 ft. 2 in. depth of hold and their two-cylinder side-lever paddle engines of 740 i.h.p. (indicated horsepower) being sufficient for an average speed of nine knots in favourable circumstances. Charles Dickens crossed on the "Britannia" in 1842. The coal supply of these ships was the chief anxiety of their designers, and their passenger accommodation was not equal to the sailing packets which they rivaled, but the regularity of their passages compensated for the fact that they were frequently beaten by the sailing ships in a fair wind. They were barque-rigged and had a considerable area of canvas which was set whenever circumstances were favourable.

4. Long-Distance Steamers.—In the meantime, although the North Atlantic crossing had attracted popular attention to the exclusion of most other services, great progress was being made in the long-distance routes. When the General Steam Navigation Company was founded in 1824 its promoters had the intention of running steamship services all over the world as material improved, and had every confidence that this would come about.

In 1825 the steamship "Enterprise" had proved that it was possible for a steamer to reach India, although at the same time it proved that it was not a commercial proposition. It had been suggested in 1822 to establish a company for the purpose of maintaining a steam service to India and a naval officer was sent out to arouse popular enthusiasm. Within two years 80,000 rupees had been raised in Bengal by public subscription, to which the government of India added 20,000 rupees and announced that the whole sum would be given as a prize to the first steamer that could contrive two round voyages between Great Britain and India before 1826, the stipulated time for each passage being 70 days.

This prize caused a syndicate to purchase the paddle steamer "Enterprise" of 470 tons when under construction on the Thames and to fit it out with a fore-and-aft rig to compete for the prize. Its dimensions were 122 ft. by 27 ft. and it had an engine of 120 nominal horsepower which was designed for nine knots speed but which could be relied upon for six or seven only. The "Enterprise" sailed from Falmouth on Aug. 16, 1825, and reached Calcutta 113 days out, including 10 days spent coaling at St. Thomas and the Cape of Good Hope. The government of India awarded it half the promised prize and then purchased it as a warship.

The improvement and finally the real practicability of the overland route was brought about by the Peninsular and Oriental Steam Navigation Company, which started in 1834 to maintain a mail service between Great Britain and the Spanish and Portuguese ports in competition with the sailing mail packets maintained by the government. It was then the Peninsular service, but in 1840 the service was extended to Alexandria to connect with the East India Company's steamers and the company became the Peninsular and Oriental Steam Navigation Company. It was not until 1854 that the East India Company abandoned its end of the service, although its irregularities and the poor steamships employed on it were the cause of constant complaint.

Steamships of a type practically identical with those of the Cunard Line, but of rather greater tonnage varying from 1,700 to 1,900, were built in 1841 for the West Indian mail service for which the Royal Mail Steam Packet Company had obtained a royal charter. At that period the British West Indian colonies were of much greater importance than in more modern times, and the service was heavily subsidized in order to overcome the great difficulties of coal supply on the route. This service was afterward extended to the Brazilian coast and the Rio de la Plata, causing a steady increase in the size of the ships, although they were long built on the same principle.

5. The Screw Propeller.—Private shipowners who were untrammeled by the conditions of their subsidies were anxious to improve on the paddle wheel and in 1836 both Francis Pettit Smith, an Englishman, and Capt. John Ericsson, a Swede, patented practical screw propellers although the principle was not new. The year 1839 saw a ship built to each of these principles, the "Archimedes" to Smith's patent and the "Robert F. Stockton" to Ericsson's. Neither was a large vessel, but they both proved the superior economy and power of the screw and led to more important ships being built.

The most important of these steamers was the "Great Britain," which was laid down in dry dock at Bristol in 1839 and floated out in 1843. It was noteworthy not only because of its dimensions, which were 322 ft. by 51 ft. by 32 ft. 6 in. depth of hold, which gave it a tonnage of 3,270 according to the old burden measurement, but also because it was constructed of iron in spite of the great prejudice of the navy against that material. It was designed by I. K. Brunel, whose intention was originally to make

FIG. 10.—"GREAT BRITAIN," FIRST PROPELLER-DRIVEN SHIP TO CROSS THE ATLANTIC

it a paddle steamer. But he was so greatly impressed by the performance of the "Archimedes" on a cruise round the British coast that he altered the "Great Britain" and fitted screw machinery, reinforced by a big sail area on six masts.

Its machinery consisted of a simple engine with four cylinders each 88 in. in diameter, with a stroke of 72 and with indicated horsepower of about 1,500 at 15 lb. per square inch pressure, a speed of 11 knots being obtained on trial. Its stranding on the Irish coast in 1846, when it had to withstand the gales of a whole winter in an exposed position, finally convinced shipowners that iron construction was both strong and practical.

6. Atlantic Development.—In 1847 the U.S. brought out its first transatlantic steamers, the "Hermann" and "Washington," run by the Ocean Line between New York and Bremen by way of Southampton in return for a heavy subsidy. They were ships of 1,750 tons each with paddle engines of 1,100 i.h.p. giving them a speed of 11 knots, their hulls being on the lines of the less extreme Atlantic sailing packets. They maintained their service with fair success until the reversal of the United States subsidy policy in 1857, when they were sent to end their days in the Pacific. In 1850 a second U.S. transatlantic service between New York and Le Havre was started with the "Humboldt" and "Franklin."

The straight stem of these two ships made them differ greatly in appearance from their British rivals and was an American conception adopted by E. K. Collins when he started the Collins Line (U.S. Mail Steamship Company) in 1850. The first fleet consisted of the wooden paddle steamers "Atlantic," "Arctic," "Baltic" and "Pacific," practically sister ships of 2,860 tons, with side-lever engines of 2,000 i.h.p. They were a great improvement on the existing material and although they were so well built and extravagantly fitted that it was necessary to obtain an additional subsidy they were the most noteworthy ships on the Atlantic in their day. In 1856 they were joined by the "Adriatic," of 3,670 tons gross with engines of about 3,600 i.h.p. designed for a speed of 13½ knots, which marked the high-water mark of U.S. paddle-steamer construction on the Atlantic. When the subsidy on which the company relied was suddenly withdrawn after two disasters the service collapsed and although Cornelius Vanderbilt constructed somewhat similar ships to maintain U.S. interest on the Atlantic they were soon withdrawn and for more than 30 years U.S. steamship development was practically confined to the rivers and coasts of the country and to the Pacific trade.

While these big paddle steamers were being built the screw propeller was being introduced into European Atlantic companies, beginning seriously with the foundation of the Inman Line in 1850. This company, which was intended to improve the emigrant service, began with iron screw steamers—the first of less than 2,000 tons—barque-rigged and still maintaining a full spread of canvas. Its example was soon followed. The North German Lloyd (Norddeutscher Lloyd) and Hamburg-American (Hamburg-Amerika Linie) companies in Germany, and the Compagnie Générale Transatlantique in France, saw the opportunities of the great continental fields of emigration with up-to-date steam tonnage and were soon encroaching on the third-class traffic which was the last stronghold of the sailing packet.

The Cunard Line was endeavouring to carry on in its traditional way, in spite of the fact that by then the naval conditions were considerably relaxed, but it was gradually being forced into line. For its mail ships it remained faithful to the paddle until the early 1860s, the "Scotia" of 3,871 tons which was launched in 1861 being the last and finest of the type. It had, however, changed from wood to iron with the "Persia" of 1855. The first Cunard screw steamer was the "China" of 2,529 tons, built in 1862, which in spite of its smaller size showed its advantages in competitive service trials.

7. "Himalaya."—In 1853 the Peninsular and Oriental Line, although not destined to abandon the paddle for several years afterward, built the iron screw steamer "Himalaya," which was the largest vessel of its type in the world, having a gross tonnage of 3,438 on dimensions 340 ft. by 46.2 ft. by 34.9 ft. depth of hold. Its trunk engines gave it a speed of 13.9 knots on trial, and yet were sufficiently economical to permit it to stow enough fuel to undertake long voyages under steam which showed a profit. After one or two voyages on its owners' service it was taken up as a transport for the Crimean War and so impressed the admiralty that they bought it and employed it as a naval trooper until the 1890s. It was then converted into a coal hulk for use at Portland, where it was destroyed in World War II.

8. "Great Eastern."—The "Great Eastern" was one of the most discussed steamships ever built, and the most historic failure. It was originally conceived by I. K. Brunel on the success of the "Great Britain," and in 1851 a company was floated for the purpose of building it and trading to the East. At that period steam navigation to the East and Australia was greatly handicapped by the lack of coaling facilities, and the "Great Eastern," was specially designed to ply between England and either Calcutta or Colombo, where smaller steamers and sailing vessels could pick up its cargo and passengers and distribute them to various destinations. Its dimensions of 692 ft. on the upper deck by 82.5-ft. beam and 30-ft. draft gave it a gross tonnage of 18,914, and it became necessary to take particular precautions that its hull should have the requisite strength. It was, therefore, given not only a double bottom but a tubular upper deck and was one of the strongest ships ever built. The hull and the paddle engines were built by Scott Russell and Company on the Thames, while James Watt and Company of Birmingham built the screw engines, for Brunel had decided to provide alternate methods of propulsion, the greatest fault in the original design. Scott Russell of the building firm designed the details of its hull and gave it the wave-line principle in which he believed. The paddle engines had 3,411 i.h.p., while the screw engines which drove a four-bladed propeller had 4,886 i.h.p. Altogether 6,500 sq.yd. of canvas were set on its six masts and it was fitted with ample bunker accommodation for a long voyage, in addition to large holds and passenger accommodation. Fearing for the narrowness of the river, Brunel insisted that it should be launched broadside on and was so anxious to avoid the huge mass taking charge that he checked it too soon on the ways and it stuck fast for three months. This delay, and the subsequent work of launching it, drove the original company into liquidation and it was purchased for use on the North Atlantic, a service for which it was most unsuitable. The result was that it was a most expensive failure except for the work that it did in laying the Atlantic cable.

9. Steam Colliers.—By this time the screw steamer was invading most of the trades of the world, including the coastal. The U.S. was building up a fine coasting fleet, differing very materially from European ideas of design. Most of the European nations were following suit, while steam colliers were even invading the coal trade between the northeast coast of England and the Thames, which was regarded as the stronghold of the sailing ship. The first was the 273-ton "Q.E.D.," which was really an auxiliary, schooner rigged, with the smoke from its low-powered screw machinery carried up through the mizzenmast. This vessel made its appearance in 1844. Eight years later, however, the first real iron steam collier was put into service, the "John Bowes." This steamer had dimensions 151 ft. 9 in. by 26 ft. 3 in. and was one of the first ships to be fitted with tanks for water ballast. Rebuilt out of all recognition, it was later transferred to the Spanish coasting trade as the "Valentin Fierro."

An important result of the success of the "John Bowes" was that it caused the introduction of the steam tramp, a cargo vessel which was open to charter on any trade instead of running to a definite schedule. Before that time all steamers were built for definite services and chartering for bulk cargoes was unusual, this business being left almost entirely to the sailing ship.

10. The Compound-Expansion Engine.—Increased economy was still the aim of the engineer, and this led to the introduction of the compound-expansion engine, in which the steam was used in a second cylinder at a lower pressure after it had done its work in the first. It was an invention of James P. Allaire, U.S. engineer, in the year 1824, but at that time it failed because of the low pressure used. As steam pressure increased John Elder, the head of what later became the Fairfield Shipbuilding and Engineering Company on the Clyde, brought out his compound engine, which employed the steam in two stages and which did much to overcome the disadvantages of the steamship on long routes on which coaling stations were rare.

The first vessel to be so fitted was the "Brandon" of 1854, a screw steamer designed for the trade between London and Limerick and fitted with a vertical engine having the cranks diametrically opposite to one another. Its coal consumption on trial was returned as 3¼ lb. per indicated horsepower per hour, as compared with the 4 to 4½ lb. which was the utmost economy to which the simple engine could aspire. Although built for a short-distance service, it was employed as a transport in the Crimean War and its success caused the compound engine to be generally adopted, while the steam pressure steadily increased. The first Atlantic steamship to be fitted with compound-expansion engines was the "Holland" of the National Line in 1869.

As pressures still increased it became possible to add a third stage to the engine and triple-expansion machinery came into being. In France this system was sponsored by Benjamin Normand of the famous firm of Le Havre shipbuilders, who took out a patent in 1871 and installed his first set two years later. In England a patent was taken out by A. C. Kirk, a colleague of John Elder, who tried a triple-expansion engine and machinery first in 1874 in the 2,083-ton steamer "Propontis."

11. Water-Tube Boilers.—The original installation of the "Propontis" was fed by water-tube boilers, in which the water passed in tubes through the flame instead of the flame passing in tubes through the water as in ordinary mercantile practice. These boilers, which were later generally adopted in all navies and in many merchant ships, had already been introduced in France but had given much trouble. Those installed in the "Propontis" were no more satisfactory than those of French men-of-war which had been so fitted in the 1840s, and it is generally described as a failure, but when new boilers were installed with reduced pressure it continued to work satisfactorily for many years.

In 1881 the "Aberdeen" of 3,616 tons, designed to run on the Australian trade in which economy was more obviously necessary than in any other, was fitted with Kirk's triple-expansion engines. On trial it reduced its coal consumption to 1.28 lb. per indicated horsepower per hour and was a most satisfactory vessel on service, although this abnormally small consumption was naturally increased under working conditions. Its success caused a large number of steamers of all kinds, which had originally carried compound engines, to be tripled by the addition of a third cylinder during the 1880s and 1890s.

At the end of the 19th century steam expansion was taken one stage further, to obtain the best economy with steam pressures above about 180 lb. per square inch, and quadruple-expansion engines were built for marine use. Such engines were fitted in 1904 on the twin-screw "Caronia" of 19,687 tons, which was the last Cunard liner to be fitted with reciprocating engines. Its sister-ship, the "Carmania" (19,524 tons) of 1905, marked the transition of the Cunard Line to turbine propulsion.

12. Twin Screws.—In 1862 the first full-powered twin-screw steamer, apart from certain experiments in the earliest days of steam, was built on the Thames. It was the 400-ton "Flora" and although its builders, the Dudgeons, made a specialty of twin-screw steamers and built the far larger "Ruahine" in 1865 for the Panama, New Zealand and Australian Royal Mail Company, the idea did not attract the liner companies until the "Notting Hill" of 1881 proved the advantages of the system on the North Atlantic. Even so the single screw was not abandoned at once and as late as 1896 first-class liners were built with one shaft only, in spite of the uneasiness caused by several serious accidents.

13. Turbine Ships.—The experimental "Turbinia," built at Wallsend on the Tyne in 1894 and given turbine engines invented by Sir Charles Parsons, revived one of the earliest principles of generating power and proved that it was capable of being used at sea. Its dimensions were 100 ft. by 9-ft. beam by 3-ft. draft, its displacement being 44½ tons. The original machinery installation consisted of three steam turbines, totaling 2,000 s.h.p. (shaft horsepower) and each driving a shaft carrying three screws in order to overcome the disadvantages of high propeller speed. During the Diamond Jubilee naval review of 1897 it was taken down to Cowes secretly and suddenly dashed out among the assembled ships at what was then the astounding speed of 34½ knots. Naturally it caused a great sensation and the admiralty built two turbine destroyers which unluckily came to grief, one by stranding and the other because of its light construction. There was a tendency to blame the machinery, which had nothing to do with either mishap, and it was some time before Parsons could persuade commercial shipowners to take an interest in his invention.

The "King Edward" of 1901 was the first merchant steamer to be given turbine machinery, a Clyde passenger steamer which ran for a considerable time after material alterations. It was followed by the cross-channel packet "The Queen" of 1903, which proved itself greatly superior in speed and far more economical than the reciprocating-engined steamers which had preceded it on the service between Dover and Calais. The next important ships to be fitted with turbines were the Allan liners "Virginian" and "Victorian" of 1904, ships of about 10,750 tons gross each with a trial speed of nearly 20 knots. With all these ships there was a certain amount of trouble in the early days, but the turbine made progress and proved its reliability in the Cunard liner "Carmania," whose success resulted in the turbine's being adopted for the Cunard steamers "Mauretania" and "Lusitania" which were the biggest and fastest liners in the world when they were built in 1906. The "Mauretania" held the blue riband of the Atlantic for 22 years.

The 22-ft. steam launch "Charmian" was the first vessel in which intermediate gearing between the turbine and the propeller was tried, the experiments taking place on the Tyne as early as 1897 and being practically contemporary with similar experiments carried out on the continent. It had long been realized that the efficient speed of the turbine was far too great for the propeller, which was the reason why multiple screws were fitted to the shafts of the early passenger steamers. In 1909 these experiments had produced sufficient promise to warrant the cargo steamer "Vespasian" having its old triple-expansion engines taken out and turbine machinery with single-reduction mechanical gearing substituted. The great increase in speed and economy which was immediately obtained drew attention to the possibilities of the turbine for cargo as well as fast passenger vessels, and from this it became evident that the gearing, whether it was single or double reduction, was of the greatest advantage even at the maximum speed so that the direct coupled turbine came to be regarded as obsolete at sea.

14. Introduction of Steel.—Improvements in the hulls of steamers were introduced steadily while machinery was being improved, principally with the idea of increasing the strength and carrying capacity and reducing the weight of hull necessary. Iron had shown itself to be superior to wood in these respects, and the next step forward was the introduction of steel for shipbuilding. The first steel-hulled vessel to cross the Atlantic was the paddle steamer "Banshee" of 325 tons, built at Liverpool in 1862 for use as a blockade runner in the American Civil War. In 1876 a small steel paddler was built for river service in Burma and in the following year the Royal Navy built two fast dispatch vessels, the "Iris" and "Mercury." The first sizable merchant ship to be so built was the "Rotomahana," a ship of 1,777 tons built by William Denny on the Clyde for the Union Steamship Company of New Zealand in 1879. Within a few months it was followed by a

much bigger and more important ship, the Allan liner "Buenos Ayrean" of 4,005 tons, for the Canadian mail service. Although it was recognized that steel offered advantages in every direction except, possibly, durability, its general adoption was checked by the difficulty of obtaining supplies; however, in the early '80s this was overcome and many steel ships were constructed.

The form of the hull was also the subject of numerous experiments in the constant effort to increase the carrying capacity on the same or smaller tonnage, and for this reason several revolutionary designs were brought forward. One of the most striking and permanent of these was the turret deck steamer which was evolved and built by the Doxford shipyard of Sunderland. In this type a curve in the side above the water line resulted in a narrow deck with a broad extreme beam, and for some time it permitted a great economy in harbour and canal-transit fees, since these often were computed on the basis of the cargo capacity of the first deck above the water line.

The "Turret" of 1892 was the first ship of this type and was laid down by the Doxford shipyard on speculation but bought by Peterson Tate and Company for the Canadian trade. Other steamship lines took up the turret deck steamer enthusiastically, particularly the Clan Line, but many of its advantages were negated by the amendment of port and canal regulations, and although these steamers were capable of carrying a large cargo and were excellent sea ships if properly treated, in inexperienced hands they were apt to give trouble and so gradually fell out of favour.

Welded steel-hull construction was tried about 1916, and the first sizable merchant ship to be all welded, without any rivets in its hull, was the M.S. "Fullagar," built at Birkenhead in 1920.

VII. MOTOR SHIPS

The Caspian steamer "Wandal," which was built by the firm of Nobels in 1903, was the first sizable ship to be given an internal-combustion engine, but in this case it was used to generate electricity for the main drive.

Engines in which the charge was exploded by a hot bulb or an electric spark were found suitable for small craft soon after they had become general in automobiles on land, but their size was strictly limited. In the year 1892 Rudolf Diesel took out his patent for an engine in which the charge was exploded by raising its temperature by compression while it was still inside the cylinder, and ships propelled by such units, built up to large sizes and considered by many to be preferable to steam plants, are invariably termed diesel-engined.

The "Wandal" was followed in 1906 by the "Venoge," a motor barge on Lake Geneva, and in 1910 the motor tanker "Vulcanus" of 1,179 tons marked a great improvement in size. One year later the motor ship "Selandia" was commissioned by the East Asiatic Company, Ltd., of Denmark, one of the principal advocates of the diesel engine, and ran successfully until 1942. Its dimensions were 370 ft. by 53.2 ft. by 27.1 ft. depth of hold, its gross tonnage being 4,950. It was a twin-screw ship, each shaft being driven by an eight-cylinder four-stroke-cycle engine with cylinders 20⅞ in. in diameter by 28¾ in. stroke, totaling a brake horsepower of 2,450 at 140 r.p.m. and driving it at a speed of 11 knots. It was rigged as a three-masted schooner and the absence of funnel attracted general attention. Most shipowners continued preferring to run the exhaust from the engines up through funnels, making their motor ships practically indistinguishable from steamers.

After the success of the "Selandia," for although all the early diesel-engined ships had a certain amount of difficulty with their machinery it was a distinct success and economical, a series of ships was built steadily improving in size, efficiency, and economy. World War I practically held up experimental work in that connection as far as merchant ships were concerned, but the diesel improved rapidly in submarines and the Germans brought it to a high pitch of perfection. In Great Britain the results of admiralty experiments were also placed at the disposal of the mercantile engineers at the end of the war. Several submarine diesels were fitted into German cargo ships after the war, their speed being geared down to the efficient speed of the propeller as in the case of the turbine, with satisfactory results.

To begin with, the diesel engine was more or less confined to the cargo vessel, but after World War I it was seen that its adoption in large passenger vessels would mean a considerable saving in space and running costs, although the first costs were considerably higher than in the case of the steamer. After several trials in comparatively small ships, in 1924 the "Aorangi" of 17,491 tons was built at the Fairfield yard on the Clyde for the Union Steamship Company of New Zealand and proved most successful on the service between Vancouver and Australia. It was followed in 1925 by the "Gripsholm" of the Swedish American Line, a ship of 18,134 tons designed for service between Sweden and the United States. There was considerable doubt as to the wisdom of building this ship, for the diesel shows to its best advantage on long runs, but it proved an unqualified success. In the same year a great advance in tonnage was made with the 22,048-ton "Asturias," built at Belfast for the Royal Mail Steam Packet Company, and the diesel-engined passenger liner became firmly established. Harland and Wolff, Ltd., the builders of the "Asturias," specialized in a big double-acting diesel built on the lines of Burmeister and Wain of Copenhagen, one of the earliest diesel builders.

The "Augustus" of 30,418 tons was built for "Italia," Società Anonima di Navigazione, in 1927. In deference to public opinion all these large passenger motor ships were given funnels, the majority of them two, but the builders evolved a typical diesel funnel, short and stout, which does much to obviate the echo which can prove exceedingly troublesome when the exhaust is carried through a funnel of ordinary design, particularly in fog.

1. The Still Engine.—In the Scott-Still engine, first fitted in the Blue Funnel liner (A. Holt and Company) "Dolius" of 5,507 tons in 1924, an effort was made to combine the steam and diesel systems, but although a certain economy was obtained, the system did not become a commercial success.

2. Electric Drive.—Electric propulsion at sea, with power generated by the internal-combustion engine, was first tried by Nobels in the "Wandal" on the Caspian in 1903, a vessel that has already been mentioned as the first motor ship. The German Navy adopted it for use on the submarine salvage vessel "Vulcan" in 1907 and it was also tried in 1913 in a Canadian lake vessel, the "Tynemount," where the current was generated by two diesel engines of 250 b.h.p. (brake horsepower). It was followed by the Swedish "Mjölner," in which the current was generated by two turbines of 450 s.h.p. each. The U.S. Navy, which later brought the system up to its highest pitch of perfection, first tried it in the steam collier "Jupiter" of 20,000 tons displacement, in which the turbine generator was of the Curtiss type and where the results were so successful that the system was adopted in the latest and largest battleships. The "Jupiter" later became the aircraft carrier "Langley." For cruisers and destroyers, however, the United States naval authorities found mechanical gearing better.

After World War I there was a growing tendency to favour electric propulsion for merchant ships, particularly in the U.S., and with the benefit of the experience gained in the U.S. Navy it was possible to install large power plants with perfect success. The most striking case was the Panama-Pacific liner "California," employed on the intercoastal trade between New York and California. It was a ship of 20,325 tons built in 1928, its electric machinery generated by turbines giving it a speed of 18 knots. A similar installation was chosen for the Peninsular and Oriental liner "Viceroy of India," launched on the Clyde in 1928, and the French liner "Normandie" was fitted in 1932 with turboelectric drive of 160,000 h.p.

VIII. STEAMERS FOR SPECIAL PURPOSES

1. Tugboats.—The use of steam power for tugboats was considered from the earliest times. In 1736 Hulls patented his proposal for a steam-propelled tugboat to carry vessels into and out of harbour in a calm. This he described in considerable detail, the vessel was to have a Newcomen steam engine of 30-in. cylinder diameter, fitted with ratchet gear to produce rotative movement of a paddle wheel at the stern. This scheme, so far in advance of its time, met with derision and never had a practical trial.

The first practical tugboat was the "Charlotte Dundas" of 1802

tried on the Forth and Clyde Canal, but condemned because the canal owners feared that the wash from its paddles would cause damage to the canal banks.

The first steam tugboat on the Thames was put into service in 1816; and the first steam vessels in the British Navy, from about 1822 onward, were used as tugboats, to tow the sail warships in and out of harbour. Screw propulsion for tugboats was first tried in the United States about 1850 and soon came into general use. In 1875 triple-screw tugs were in service on British inland waterways.

In the course of World War II a class of ocean tugboat was developed for rescue and salvage work. One notable vessel of this class was the "Turmoil" of 1,800 tons displacement, built in 1944 for the British Admiralty. Its dimensions were 205 ft. by 38.5 ft.; it had diesel engines of 3,200 total b.h.p. and was capable of 15 knots.

For modern ocean liners, the use of tugboats in berthing and docking operations is normally considered indispensable; but it is on record that on Feb. 6, 1953, the "Queen Mary," in exceptional circumstances, was able to berth at New York under its own power and without the help of tugs.

Even after the screw had been adopted for the propulsion of tugboats, the paddle wheel still continued to be used for this purpose, and in 1955 some paddle tugs with diesel-electric drive were built for the British Admiralty.

2. Train Ferries.—The 417-ton steam train ferry "Leviathan," built in 1849 for the North British Railway Company to run across the Firth of Forth from Granton to Burntisland, was the first of a type which later became quite general and was built to large size on several services. Almost at the same time another was built to cross the Tay at Dundee, but both these ferries were later replaced by bridges. In 1878 the Philadelphia and Reading Railroad built its first ferry steamer to run across New York Bay and in the early 1880s the Danes started a train ferry from Korsor to Nyborg. The idea of a similar service to run across the Straits of Dover was put forward in 1870, when the use of double-ended paddle steamers was proposed. Train ferries were introduced in 1936 between Dover and Dunkirk, in connection with the direct London-Paris service. Another train ferry on a large scale in Great Britain is that running from Harwich to Zeebrugge and employed largely for shipping French and Italian fruit to England.

3. Steam Trawlers.—In the early 1870s several attempts were made to introduce steam trawlers in the south of England, but they were not successful. Several years later a shipping slump caused numerous steam tugs to be laid up and the experiment of using some of these for trawling was tried. Most of these were paddlers, the first being the "Messenger" which made its first trip to the fishing grounds in 1877, but the experience gained in it and other converted ships showed that the paddle was unsuitable for trawling. Experiments with screw boats were tried in the early 1880s and were an immediate success, the design developing rapidly and producing some of the finest sea boats afloat. Later, practically every maritime country acquired a big fleet of power trawlers and drifters. The internal-combustion engine made great strides in vessels of this type, and electric machinery was also tried on occasions.

4. Icebreakers.—"Eisbrecher I," launched in 1871, was the first specially designed icebreaker to be built. It was planned on the experience gained a few years previously by a Russian shipowner named Britneff, who reconstructed the bow of the steamer "Pilot" in such a way that it could be driven onto the ice in the hope that it would break it by its own weight. In practice it was too small and light for this purpose, but the idea was appreciated and is embodied in all modern icebreakers, some of which run to a large size. *See* ICEBREAKERS.

5. Tankers.—The increased consumption of oil for various purposes made it necessary to evolve some means of carrying it in bulk instead of in barrels as it had been carried from the earliest days of whaling. The first suggestion was in 1863, when the sailing vessel "Ramsey" had a few tanks built into its hold to carry oil in bulk in addition to stowing barrels in the ordinary way in its 'tween decks. From 1869 to 1872 the sailing vessel "Charles," of 794 tons, was carrying oil in 59 iron tanks which were built into its holds and which completely filled them. The problem of keeping ironwork oiltight was not then fully understood and these tanks were far too weak, with the result that in the working of the ship under sail constant leaks developed and eventually it was burned at sea. Several other ships were converted in similar fashion, mostly for the trade across the Atlantic to Le Havre and Antwerp, but they were all failures.

In 1872 the Red Star Line of Philadelphia started a new system by having the steamship "Vaderland" of 2,748 tons built by Palmer Brothers and Company on the Tyne with the idea of carrying a large cargo of oil in bulk in addition to its passengers. All the authorities were against this scheme on grounds of safety, and it was used for passenger and cargo only, as were also the "Nederland" of 1873 and "Switzerland" of 1874 which were designed on similar lines. This prohibition against shipping oil in passenger vessels still exists.

In 1879 Nobels, who were already noted for their work in building the pioneer motor and electrically driven ship, built a number of tank steamers to carry oil on the Volga River and attained considerable success with them. These steamers attracted some attention at the time, but the idea that oil would be safer in a sailing vessel than a steamer was still generally held and in 1886 the sailing ships "Andromeda" and "Crusader" were fitted with cylindrical tanks on an improved system for the purpose. Their designers attained a considerable measure of success in making their tanks oiltight, but in the same year the firm which later became Sir W. G. Armstrong Whitworth and Company, Ltd., designed and built the first real tank steamer on modern lines.

The "Glückauf" had a dead-weight capacity of 3,000 tons and a speed of 10½ knots, its engines being placed right aft for safety as is still almost invariably done in tankers. Its hull was subdivided into tanks, and arrangements were made for pumping them on a principle which is still used.

After World War I a large number of tank steamers were built, although it is one of the most difficult trades to cater for and to maintain. In spite of numerous experiments oil remained almost invariably a one-way cargo, so that the ship had to be exceedingly economical because of the return journey in ballast. A large cargo is desirable for the ocean route, and 13,000 tons dead weight and more became a usual size, while the speed seldom exceeded 11 knots.

After World War II, however, there has evolved a class of supertanker. One such notable vessel was the "Spyros Niarchos," built at Barrow in 1955 for the Neptune Tanker Corporation. Its dimensions were 757 ft. by 97.2 ft., with a dead-weight capacity of 47,750 tons. The hull was longitudinally framed and nearly all welded. The vessel was propelled by geared steam turbines of 18,000 s.h.p. at a normal service speed of 17 knots. The greatest shipbuilding activity of the 1950s was in tanker construction. By the mid-1960s tankers of more than 150,000 tons dead weight were in service with lengths of up to 1,000 ft. and widths of more than 140 ft. Tankers were constructed not only for transporting oil, but also for carrying liquid chemicals, gases, molasses, and fruit juices. Because of their tremendous length and unequal strain, the design of these tankers involves careful considerations of strength, and all modern types are built on the longitudinal system, with great attention paid to fore-and-aft stresses. (*See also* TANKER.)

6. Packet Steamers.—After the screw superseded the paddle for transoceanic work, the latter survived in the excursion steamers round the British coast, where shallow draft was generally necessary to get alongside the piers, and in the cross-channel services. The growing continental trade and the limitations in draft imposed by the French and Belgian harbours brought the paddle packet steamer to a high pitch of perfection in the last days of the 19th century, ships of considerably more than 2,000 tons gross with a speed of 22 knots and excellent seaworthiness being built in considerable numbers, mostly on the Clyde. No more of these big cross-channel paddlers were built after the turbine had proved its possibilities, but many other steamers propelled in this way, much smaller and rather slower, were built for the various ex-

cursion routes in the summer. Most of these again were excellent sea boats and were able to perform valuable mine-sweeping service during World Wars I and II.

In the United States, however, where the huge inland waterways favour the side wheel, the paddle steamer was brought up to its highest state of development. Notable ships of this type were the "Greater Buffalo" and "Greater Detroit," built in 1923 for service on the Great Lakes, each having a gross tonnage of 7,739 and being driven by three-cylinder compound engines.

7. Standardized Ships.—In the early days of World War I mercantile construction was almost completely suspended in Great Britain, Germany, and France in favour of warships, but it received a great impetus in the United States. When the German submarine campaign caused an acute shortage of tonnage it had to be resumed in an intensified form in Britain, while from 1917 the U.S. launched a shipbuilding campaign unprecedented in the history of the industry. In order to save time and money wherever possible, standardized shipbuilding came into vogue. It had existed within certain establishments for many years, the German yards, particularly, specializing in certain types and turning out large numbers of sister ships for various owners. During the war, however, it was greatly expanded in many countries, and in some cases inland steelworks, usually employed on bridge construction and the like, were utilized for fabricated ships with lines as straight as possible which were only put together and launched in the shipyards.

In the United States wood was largely used, both for full-powered ships and auxiliaries, but there was no time to permit the timber to season and they were built of green timber. Similarly a number of vessels of various types—lighters, tugs, tankers, etc.—were built of ferroconcrete, the rapidity with which they could be turned out compensating for their excessive weight in wartime, although only one or two of them survived more than a few months of peacetime trading.

In criticizing these standard ships built during World War I, there was a general tendency to forget the peculiar circumstances in which they were built and the necessity of getting something that would float into the water as quickly as possible. Their utility in competitive trading in peaceful circumstances was a secondary consideration. The United States Shipping Board, formed to operate the tonnage so built in the U.S., was left with a large number of ships for which no purchasers or managers could be found, though many of them were later converted to diesel or electric power and their running expenses greatly reduced.

In the later years of World War II, quantities of standardized cargo vessels, called Liberty ships, were built in the United States. These were oil-burning ships; a fairly large number of such ships were built by Canada as coal burners. "Standardization and no changes" was an outstanding feature of World War II shipbuilding. The largest number of ships ever built in the world from one design was the Liberty ship. Another outstanding feature was the use of all welding in construction. Welding was not a new process but it was developed and used to a far greater extent than ever before, being applied not only to cargo vessels but also to all classes of ships.

8. The Cabin Liner.—From the early days of regular services, the older and smaller units of the various companies were put on intermediate services at reduced prices, and these ships gradually came to be known as cabin-class ships. Few ships were specially built for the class until 1914, when Canadian Pacific Steamships, Ltd., commenced a long series with the "Metagama" and the "Missanabie," ships with a gross tonnage of about 12,500 and speed of 16 knots, having accommodation for 520 passengers in the cabin class, paying a fare approximating the second-class fare in the bigger ships, and 1,200 in the third class. Afterward the type was taken up enthusiastically by various companies, particularly on the North Atlantic, with such vessels as the "Duchess of Atholl" and her sisters, also owned by the Canadian Pacific Line, having a gross tonnage of roughly 20,000, a sea speed of 17 knots and single reduction-geared turbines supplied by oil-fired high-pressure boilers which gave the remarkable economy of 0.64 lb. of oil fuel per shaft horsepower per hour for all purposes.

9. Fast Cargo Liners.—There was also a noteworthy tendency to build fast cargo liners after World War I, ships with a sea speed of 14, 15 and 16 knots, but carrying cargo only on regular schedule. Both steamers and motor ships were built for these services and found great favour with shippers. Great economy in operation was obtained, with the result that they secured a considerable proportion of the trade which was formerly carried by tramp steamers.

10. High-Pressure Steam.—In steamers this remarkable economy was made possible largely by the employment of high-pressure steam. The Clyde passenger steamer "King George V," built by William Denny and Brothers (Ltd.) in 1926 in conjunction with Yarrow, the boilermakers, and the Parsons Marine Steam Turbine Company, had the first noteworthy installation apart from unsuccessful experiments made about 1880. It was a steamer of 801 tons gross, burning coal under water-tube boilers working at a pressure of 550 lb. to the square inch with the steam temperature raised to a maximum of 750° F. This ship considerably exceeded its contract speed of 20 knots on trial and proved a success in many ways, particularly with regard to economy. But numerous adjustments and alterations had to be made after its launching.

In modified form high-pressure steam resulted in considerable economies, both in fuel consumption and weight. The general tendency was to increase the pressure both for naval and for mercantile work, and 450 lb. became quite usual. While high-pressure steam saw its beginning in 1926, it developed rapidly in use, and in the 1930s very high-pressure and very high-temperature steam installations were made in U.S. Navy destroyers greatly increasing their speed.

These principles were adopted in whole or in part by merchant vessels and became standard practice; *e.g.*, the tanker, "Atlantic Navigator," built in 1951, was equipped with boilers operating at a pressure of 650 lb. per square inch and a temperature of 1,020° F.

11. Gas-Turbine Propulsion.—The earliest recorded description of a gas turbine (in which the hot gases of internal combustion, instead of steam, act on the turbine blades) can be found in the patent obtained by John Barber, of Nuneaton, in 1791. The first vessel to be propelled at sea by a gas turbine was the 110-ft. triple-screw motor gunboat no. 2009 of the British Admiralty, which in 1947 had a gas turbine of 2,500 s.h.p. fitted to the centre shaft. The first ship of the mercantile marine with gas-turbine propulsion was the motor tanker "Auris" of 12,250 tons dead weight, built in 1947 at Newcastle for the Anglo-Saxon Petroleum Co., Ltd. In 1951 one of its four main diesel engines was replaced by a gas-turbine installation of 1,200 b.h.p., constructed by the British Thomson-Houston Co., Ltd.

12. Express Luxury Liners.—The White Star liner "Oceanic" of 1871 was the first of the modern type of express luxury liner, which attracts more attention than any other type, but which can exist economically only on the direct service between Europe and the United States. The White Star Line had then just been founded for the purpose of engaging in the Australian trade, and for that purpose had bought the name and house flag of one of the most famous of the clipper ship companies. Events caused the directors to change their intentions and the first ships were put on service between Liverpool and New York, the "Oceanic" being the pioneer. These ships differed materially from the accepted type of screw steamer, having more than ten beams to their length and being designed on the somewhat revolutionary lines advocated by Sir Edward Harland of Harland and Wolff, the Belfast shipbuilders. The tonnage of the "Oceanic" was 3,707 and while it was fully rigged as a four-masted barque its single-screw engines gave it a sea speed of 14.75 knots. After being generally condemned on theoretical grounds by the experts, it proved itself an unqualified success. Three years later the "Germanic" and "Britannic" were built, each with a gross tonnage of 5,000 and speed of 16 knots.

The Guion Line, which had been engaged principally in the emigrant trade, then entered the race for the Atlantic blue riband with the "Arizona" of 1879, a ship of 5,147 tons with a sea speed of 16.25 knots. An improved edition of the same design was the same company's "Alaska" of 1881, its gross tonnage being 7,142 and its speed 17.75 knots. In the "Oregon," which was

built just before the company got into serious financial difficulties, and which eventually sank in collision with a small schooner, the gross tonnage went up to 7,375 and the speed to 19 knots.

The reply of the Cunard Line was the construction of the "Umbria" and "Etruria" at the same establishment which had turned out the big Guion ships, Elder's Fairfield yard. They were ships of 8,120 tons with a speed of 19.5 knots and they marked the final development of the single-screw express liner on the Atlantic. Although they were specially designed to compete with the "Oregon," that ship had passed to the Cunard Line before they were completed.

The next great improvement was the design of the "City of New York" and "City of Paris," when the twin-screw system was adopted for express ships. They were built for the Inman Line in 1888 but were better known under the flag of the American Line to which they were transferred in 1893. These ships secured the Atlantic blue riband and were the last big Atlantic liners to be built with the old-fashioned clipper stem. When it was desired to transfer them to the American Line, congress permitted them to hoist the U.S. flag only on condition that two ships of at least equal tonnage were built in U.S. yards, which resulted in the "St. Louis" and "St. Paul," of 11,630 tons and 21 knots speed, being built in 1895, the first large Atlantic liners to be built in the United States since the 1860s.

The White Star Line replied to these ships with the "Teutonic" and "Majestic" in 1889, ships which had a great struggle with the "City of New York" and "City of Paris" for the Atlantic record. In 1893 the Cunard Line secured the blue riband without doubt with the "Campania" and "Lucania" of just under 13,000 tons with a sea speed of 22 knots.

In 1897 the German companies, which had built up a big business in comparative obscurity beside the companies racing for the blue riband, came out with the "Kaiser Wilhelm der Grosse" of the North German Lloyd, which lowered the record considerably. It had a gross tonnage of 14,350 and a speed of 23 knots. Their rivals, the Hamburg-American line, built the 14,500-ton "Deutschland" to compete for the record, but on their experience with it they decided to follow the policy of comfort and good cargo capacity on more moderate speed, a policy which was also followed by the White Star Line after the "Teutonic." The North German Lloyd, on the other hand, steadily lowered its own record with the three ships which followed in the same series and to the same general design—the "Kronprinz Wilhelm" of 1901, the "Kaiser Wilhelm II" of 1902 and the "Kronprinzessin Cecilie" of 1906. Each of these ships marked a further advance in size and speed.

Before the last named could be tried at its best the Cunard Line had built the "Lusitania" and "Mauretania" with the financial help of the British government. The dimensions of the latter were 762.2 ft. by 88 ft. by 57.1 ft. depth of hold, giving it a gross tonnage of 31,938, while its quadruple-screw direct-coupled turbines had a designed shaft horsepower of 68,000, intended for a speed of 25 knots. The "Lusitania" was sunk by a German submarine during World War I; the "Mauretania" had the unique distinction of holding the Atlantic blue riband for 22 years and when 20 years old proving itself capable of steaming at 29 knots to the rescue of a disabled cargo ship.

Maintaining their policy of avoiding excessive speed, the Hamburg-American Line answered these Cunarders with the biggest steamers in the world. The first of the series was the "Imperator," later the Cunard "Berengaria." It was launched in 1912, its dimensions being 886.3 ft. by 98.3 ft. by 57.1 ft. depth of hold and its original gross tonnage 51,969. The second of the series was the "Vaterland," which became the "Leviathan" of the United States lines. Its dimensions were increased to 907.6 ft. by 100.3 ft. by 58.2 ft. depth of hold; gross tonnage was 54,282, later 59,957. The third ship was the "Bismarck," later the White Star "Majestic," similar to the "Vaterland" but slightly longer.

Immediately after World War I nearly all the lines had to engage in a shipbuilding program to replace casualties, although shipbuilding prices were at their highest level. The general tendency was to build a moderate-sized ship with good cargo capacity and comfortable passenger accommodation at reasonable rates. The Cunard Line brought out the "Franconia" type of five ships of just over 20,000 tons gross with a speed of 17 knots, while the Hamburg-American Line built four ships of the "Deutschland" type, having a sea speed of 16 knots and a tonnage of slightly more than 21,000. This tendency was broken by the Compagnie Générale Transatlantique, which in 1926 built the "Ile de France," a ship of 43,450 tons gross with direct-acting turbines of 52,000 s.h.p. and a trial speed of 24 knots. The North German Lloyd responded by laying down the "Bremen" and "Europa," ships of about 50,000 tons each, with a speed of 28 knots on service. They had geared turbines, and considerable weight was saved by a boiler pressure of 330 lb. to the square inch. Their design was revolutionary in many features, particularly in the bulb bow under the water line. The "Bremen," launched in 1928, beat all Atlantic records, but was then outstripped by the "Europa," which later became the "Liberté" of the French Line.

The first of the modern 1,000-ft. vessels was the "Normandie" of 83,423 tons, launched at St. Nazaire in 1932 for the Compagnie Générale Transatlantique. It had four screw propellers with turboelectric drive of 160,000 total s.h.p., carried 2,170 passengers and crossed the Atlantic at a mean speed of 31.2 knots. At the outbreak of World War II the "Normandie" was in New York Harbor, but was not utilized by the French for war service. On Dec. 16, 1941, it was expropriated by the U.S. Maritime Commission for a troopship. In the course of conversion, however, fire broke out on Feb. 9, 1942, and the vessel capsized. This occurred the day after the "Normandie" had been turned over to the U.S. Navy by the U.S. Maritime Commission.

The first British vessel to exceed 1,000 ft. was the "Queen Mary" of 81,235 tons, built at Clydebank and launched in 1934. It had four screw propellers 19.6 ft. in diameter, driven by turbines of 160,000 total s.h.p. In 1938 it recaptured the blue riband from the "Normandie" with a mean Atlantic speed of 31.7 knots. Another 1,000-ft. liner was the Cunard White Star "Queen Elizabeth" of 83,673 tons, built at Clydebank in 1938, carrying 2,288 passengers and propelled by turbines of 181,700 total s.h.p. supplied with steam at 450 lb. per square inch pressure.

In 1952 the 53,330-ton liner "United States," built at Newport News, Va., crossed from New York to Southampton at a mean speed of 35.59 knots (nearly 4 knots faster than the "Queen

BY COURTESY OF THE UNITED STATES LINE

SS "UNITED STATES"

Mary") and thereby reclaimed for the U.S. the blue riband of the Atlantic. The "United States" was built to the specifications of the U.S. Navy, to facilitate its rapid conversion into a troop carrier. (E. A.; F. C. Bo.; H. P. St.; E. S. L.)

IX. NEW DESIGN AND DEVELOPMENT

1. Nuclear-Powered Ships.—The late 1950s saw the advent of the nuclear-powered merchant ship. Employing the same basic design of reactor as that used by the United States for nuclear submarines, the U.S.S.R. put into service the nuclear-powered icebreaker "Lenin" in 1959, and in the same year the U.S. passenger and cargo liner "Savannah" was launched.

In Germany a nuclear-powered cargo ship was being built in 1965, but the United Kingdom postponed the construction of a nuclear ship until a reactor could be developed offering some hope of economy in operation comparable to that of a conventionally powered merchant ship. An important development was the increasing use of automatic and remote controls for ships' machinery to allow smaller crews. In Britain, closed-circuit television was introduced in 1963 to assist in the berthing of large ships. The control of main engines and auxiliary machinery began to be centred in control rooms, sometimes with alternative control of the main machinery from the bridge. Mechanization was also introduced into navigation, and the U.S. studied the development of any unmanned ocean-going vessel. Ships continued to grow in size. The most spectacular growth was that of the oil tanker, which in 1963 reached a size of 130,000 tons deadweight on the route between the Persian Gulf and Japan, where depths of water imposed no restriction; later, vessels of 190,000 tons were ordered. Ships of 80,000 tons deadweight carrying dry cargoes in bulk were in service by the mid-1960s. Change in the relative importance of fuel costs and overhead costs made higher speeds for ships economically desirable, and many cargo liners with speeds of more than 20 knots were built. Another feature of cargo liner design was the growing employment of large containers for goods at sea, the disadvantage of waste of hold space through their use being outweighed by greater ease of loading and discharge, and by better protection for the goods. To reduce manual handling of cargo, a design of ship with hatches extending virtually the full width of the ship was developed, the problem of maintaining the strength of the vessel being solved by working additional steel into other parts of it.

2. Hovercraft and Hydrofoil Craft.—Two new types of water craft, the hydrofoil and Hovercraft, came into prominence. The Hovercraft, a British invention, by the mid-1960s reached the stage where orders were being placed for commercial, passenger-carrying craft; models suitable for car ferries were also envisaged. (*See* Ground-Effect Machine.) (I. Br.)

A hydrofoil ship is one that is supported clear of the water during operation by underwater wings called hydrofoils. These wings are of similar shape and function to the wings of an aircraft, except for size. Since water is roughly 775 times as heavy as air, very small hydrofoils will support relatively heavy boats and ships, while very large wings are needed to support aircraft. Another difference is structural strength. Since operating in water imposes very great loads per unit of area on hydrofoils, they are usually built of high-strength steels, or perhaps, in the case of small boats, of high-strength aluminum alloys.

The purpose of raising the hull of boats out of the water and supporting them on hydrofoils is to avoid the resistance of the friction on the hull and the drag of wave-making that occurs when a normal boat proceeds through the water. The result at high speed is to reduce the power required to drive the boat by about half, thus permitting much higher speeds for the same size ship and engine. Another and perhaps more important result is the fact that in a well-designed foil system, the boat does not feel the impact of passing waves in rough water and up to some limited size of a seaway, can fly perfectly level and smooth, thus permitting a very small boat to fly at high speed through a rough sea that would force a conventional boat to slow down.

Hydrofoils are not new. Between 1898 and 1905 Forlanini in Italy built and flew a rudimentary hydrofoil successfully. Considerable interest was stirred among inventors of the time, and even the Wright brothers experimented with hydrofoils before their more noteworthy and successful work on the airplane. In 1918 the world's water speed record was attained by a hydrofoil powered by an aircraft engine and developed by Dr. Alexander Graham Bell and Casey Baldwin, a Canadian inventor. From this period until the 1930s interest lagged, principally because there were no high-power, lightweight engines available to make practical, usable hydrofoils. In the 1930s German inventors were on the verge of a successful seagoing ship when war halted their efforts. After World War II these efforts were renewed and the many commercial hydrofoils that are now in service in western Europe are based on German technology.

In the early 1950s the availability of higher powered gas turbines and a renewed interest in high-speed water travel resulted in the development of hydrofoils in the U.S., Canada, and U.S.S.R. Designers emphasized the military as well as the commercial utility of hydrofoils. Their efforts came to fruition with the completion in the U.S. of the first seagoing patrol craft, the U.S.S. "High Point," a 100-ton vessel designed as a military ship and not as a research tool; the production of an 80-ton commercial prototype, "Dennison;" and the operation on the rivers and waterways of the Soviet Union of passenger ferries carrying hundreds of passengers.

The problem of stabilizing a hydrofoil ship so that it moves without undue rolling or pitching, and the problem of keeping the hull the proper distance from the water have given rise to many different designs of hydrofoils and supporting struts as well as many different control systems. Most successful hydrofoil ships belong to one of two general classes: surface piercing foils and submerged foils. The simplest type, surface piercing, depends for its stabilization on providing about twice as much foil area as is necessary to support the ship, and on operating with the foils piercing the surface of the water so that they are wetted just enough to carry the ship. Then, if more lift is needed because of a shift in weight or the approach of a wave, more area is immersed.

The more complex type of hydrofoil employs fully submerged foils that are wetted at all times. In this type, changes in lifting forces are obtained by changing the angle of the foils to the flow of water until the precise lift is obtained on all foils to just support the weight of the ship. Since a fully submerged foil has no reference to the surface of the water, artificial signals must control its movements. Thus, for the submerged foil type, some mechanical or electrical means must be used to measure the height of the ship above the water and its angles of roll and pitch, and means must be provided to convert these measurements into rotation of the foils to provide the proper response. Thus, the submerged foil ship must be equipped with a system roughly corresponding to an autopilot in an aircraft.

Surface piercing hydrofoils are cheaper, simpler to operate and maintain, and are less susceptible to breakdown; the submerged type, however, is much more seaworthy, provides a smoother ride, and can operate in seas that a surface piercing ship of similar size can not. Thus, most commercial ships and those designed for river or inland waterways have been surface piercing boats, while those designed for unlimited military or open ocean service have employed submerged foils.

Although the largest hydrofoil ships have a displacement of hundreds of tons, there has been considerable controversy as to the maximum size attainable; this is because the so-called cube-square law that has limited the size of aircraft also applies to hydrofoil ships. In accordance with this law, as hydrofoils become larger, their weight increases as the cube of a linear dimension, while the foil area available to support this weight only increases as the square of that dimension. From this, it follows that, at some size, the weight will exceed the capacity of any foils to support it. The general consensus is that this limit is reached somewhere between 500 and 1,500 tons. Therefore, hydrofoil ships are limited to moderate sizes and can not replace aircraft carriers or ocean liners. They are used or planned for high-speed passenger ferries, patrol boats, attack craft, antisubmarine craft,

and other missions where moderate size and high speed are desired.

Hydrofoil ships experience a speed barrier at about 50 knots, which might be likened to the sound barrier in aircraft. At this speed the negative pressure on the top of the hydrofoils reaches the vapour pressure of water and a cavity is formed, causing lift to become erratic; the cavity then collapses, resulting in physical damage to the foils. As a result, a normal hydrofoil cannot operate at more than 50 knots. However, just as aircraft have broken the sound barrier, hydrofoils with sections shaped like an axe (supercavitating foils) instead of a normal airfoil have attained much higher speeds, in excess of 80 knots.

SHIPKA PASS, Bulgaria, a pass through the Balkan Mountains, the scene of fierce fighting in the Russo-Turkish War of 1877–78. Situated on the main road from Ruse on the Danube through Stara Zagora to Adrianople (Edirne) in Turkey, this pass was an important point in the Russian plan of operations. It was originally held by a Turkish force of 4,000 men with 12 guns, but the Russian Gen. I. V. Gurko seized it by surprise on July 19, 1877. Gen. Suleiman Pasha, who drove the Russians across the Balkans, attacked Shipka on Aug. 21. The Russian force there, including 7,500 Bulgarian volunteers, held the position against Suleiman's 30,000 Turks. The fighting continued till Sept. 26, when both adversaries entrenched themselves on the pass. After the capitulation of the Turkish forces at Pleven (*q.v.*) in December, however, the Russians began a general advance; and on Jan. 5, 1878, Gen. F. F. Radetski attacked the Turks on Shipka Pass. The fall of Pleven made Turkish resistance at Shipka strategically useless, and on Jan. 9 Gen. Vessil Pasha (who had succeeded Suleiman) surrendered. The Russians had lost 5,500 men on the pass, the Turks 13,000. The manner in which Suleiman had sacrificed his men earned for him the name of the "Shipka butcher."

SHIP LANES: *see* SHIPPING ROUTES.

SHIPLEY, an urban district in the Shipley parliamentary division of the West Riding of Yorkshire, Eng., 3 mi. (5 km.) NNW of Bradford. Pop. (1961) 29,758. Area 3.4 sq.mi. (8.8 sq.km.) Shipley is in Airedale south of the Aire River and on the Leeds-Liverpool Canal.

Mentioned in Domesday Book as Scipeleia, it was developed when Sir Titus Salt started his vast woolen mills (1853) and built the model village of Saltaire with its Italian-style Congregational Church (1859) and the Saltaire Institute (1870).

Engineering is important, but Shipley is also a residential area. The urban district (created 1894) includes Shipley, Windhill, Wrose, part of Frizinghall and Saltaire parishes.

SHIP MONEY, a nonparliamentary tax first levied in medieval times by the English crown for the defense of the country; it is primarily remembered because its enforcement as a general tax by Charles I provoked widespread opposition and led to the famous trial of John Hampden. During the Hundred Years' War the crown had exercised the right of requiring the maritime towns and counties to furnish ships in wartime, and the liability was sometimes commuted for money. Although by the 17th century it was well established that taxes (other than agreed commercial dues) could not be imposed without a specific grant by Parliament, the levying of ship money in time of war had never fallen wholly into abeyance and in 1619 James I aroused no popular opposition by levying £40,000 of ship money on London and £8,550 on other seaport towns.

On Feb. 11, 1628, Charles I issued writs requiring £173,000 for the provision of a fleet to secure the country against possible French invasion and for the protection of commerce. Every county in England was assessed. This was the first occasion when the demand for ship money aroused serious opposition and Charles withdrew the writs. After 1629, however, his determination to rule without Parliament led him to reemploy this financial device.

The first of six writs issued annually between 1634 and 1639 appeared on Oct. 20, 1634, and was directed to the justices of London and other seaports, requiring them to provide a certain number of ships of war, or their equivalent in money, and empowering them to assess the inhabitants for payment according to their substance. The distinctive feature of the writ of 1634 was that it was issued to provide for a possible future emergency rather than against a present danger. The citizens of London immediately claimed exemption under their charter, while other towns demurred to the amount of their assessment; but no resistance on constitutional grounds appears to have been offered, and nearly £80,000 was collected, all of which, as on future occasions, was spent on the fleet.

A second writ of ship money was issued on Aug. 4, 1635, directed on this occasion, as in 1628, to the sheriffs and justices of inland as well as of maritime counties and towns, demanding the sum of nearly £200,000, which was to be obtained by assessment on personal as well as real property, payment to be enforced by distress. This demand excited growing popular discontent, so Charles obtained a written opinion, signed by 10 out of 12 judges consulted, to the effect that in time of national danger, of which the crown was the sole judge, ship money might legally be levied on all parts of the country by writ under the great seal. Had this ruling subsequently gone unchallenged the king's prerogative would have become the sovereign power in the realm. The issue of a third writ of ship money on Oct. 9, 1636, made it evident that the king intended to convert it into a permanent and general form of taxation without parliamentary sanction.

Payment was refused by Viscount Saye and Sele and by John Hampden (*q.v.*). The case against the latter was heard in 1637 before all the common law judges in the exchequer chamber and lasted for six months, Hampden being defended by Oliver St. John and Robert Holborne. Seven of the 12 judges, headed by Sir John (later Baron) Finch, chief justice of the common pleas, gave judgment for the crown, and 5 for Hampden, although 2 found for him only on technical grounds. The narrowness of the king's victory strengthened the opposition to ship money and about 20% of the tax levied in 1638 remained unpaid. Charles issued a writ of ship money for the last time in 1639, but of the £210,400 demanded, only about £50,000 was collected. In 1641, by an act of the Long Parliament, ship money was declared illegal.

SHIPPARD, SIR SIDNEY GODOLPHIN ALEXANDER (1837–1902), British colonial administrator in Bechuanaland, was born in Brussels on May 29, 1837. He went to the Cape Colony in 1868 to practise law. After holding important appointments in Griqualand West as attorney general (1875–77) and as recorder of the high court (1877–78), he became a Cape supreme court judge (1880–85). When Britain formally took over Bechuanaland in September 1885, Shippard became administrator and chief magistrate of British Bechuanaland and resident commissioner of the Bechuanaland protectorate. He was knighted in 1887, and retired in November 1895.

Shippard enthusiastically approved of Cecil Rhodes's plans to extend British influence northward into central Africa and to forestall possible advance there by the Germans or by the Boers. He supported Rhodes on several crucial occasions. In 1887, for instance, Shippard pressed Sir Hercules Robinson (later Baron Rosmead), the high commissioner in South Africa, not to sanction a treaty between Lobengula, ruler of Matabeleland-Mashonaland, and Piet Grobler, who represented the Transvaal, but to send the Rev. J. S. Moffat to negotiate a treaty (February 1888) pledging the chief not to cede territory without Britain's consent. He then helped to persuade Lobengula to grant to Rhodes's agents in October 1888 the Rudd mineral concession, which became the basis of the British South Africa Company, chartered in 1889.

Shippard's complicity in the raid (December 1895) of L. S. Jameson (*q.v.*) was suspected, but never proved. He persuaded two protectorate chiefs in 1894 to let the company administer their territory on the Transvaal border, including Pitsani, the jumping-off point for the raid. He was in Johannesburg during the abortive rising in December, and publicly, though unofficially, asked the Reform committee to lay down its arms. Shippard afterward returned to England and was made a director of the British South Africa Company in 1898. He died in London on March 29, 1902.
(M. F. K.)

SHIPPING. The function of shipping is to transport goods and persons across water, that is, across the world's oceans or along its coastlines or through its inland waterways. The chief work of the shipping industry is to provide, man, and manage the vessels that carry most of the goods entering into world trade; and also to provide and maintain the ancillary services necessary for the receiving of cargoes and for their onward dispatch at ports of destination. As a transport industry it differs from most other industries in that it does not manufacture products to sell but exists to provide a service; and it performs this function almost entirely in an international field—the high seas—for the most part outside the territories of the shipowner's country of domicile. Shipping is an essential element in world commerce and is highly competitive on an international scale. It is also an important factor in the economy of the major trading nations; and, especially since the beginning of the 20th century, the possession of a merchant fleet has become important as a strategic necessity and for national prestige.

The shipping industry had its origin in the Industrial Revolution and its consequences—the invention of the marine steam engine, screw propulsion, and the use of iron, and later steel, for shipbuilding. Although the transition from sail to steam was gradual, the early steam navigation companies were the real founders of the shipping industry. The great expansion of world commerce that followed the Industrial Revolution called for a new system of ship management and shipping services, by which the ship became an instrument of world trade and an essential service to commerce, rather than a private venture on the part of a merchant trader or shipmaster or shipowner-merchant. After the opening of the Suez Canal in 1869, which sounded the death knell of the commercial sailing ship, the expansion of the volume of world seaborne trade became enormous. The development of the mechanically propelled merchant ship, and its continual increase in size, efficiency, and numbers made this growth possible.

Table I demonstrates the expansion of the world fleet of mechanically propelled merchant ships, and the decline of the sailing ship, in the period between 1886 and 1935; Table II illustrates the subsequent development of the world merchant fleet (see *World Merchant Fleets*, below). Though it is not possible to provide comparable statistics of the increase in the volume of world seaborne trade over the same period, particularly for the 19th century, League of Nations statistics estimated that by 1929 the amount of world seaborne trade had reached a level 35% higher than that in 1913. In the depression of the early 1930s the figure dropped at one time almost to the 1913 level, but by 1937 it had fully recovered to the 1929 level. According to United Nations statistics, the volume of seaborne trade reached in 1937 (490,000,000 metric tons) had again been recovered by 1948. Further, by 1962 the volume of seaborne trade had increased to 1,200,000,000 tons.

At the time of the Suez crisis (1956) there was a boom in the ordering of new tonnage. Thereafter, international trade continued to expand, but not at the rate forecast and as a result too many ships became available for too few cargoes, depressing freight rates. The depression of the late 1950s showed little sign of lifting by the mid-1960s.

For the early history of maritime commerce, *see* SHIPPING ROUTES; COMMERCE, HISTORY OF. (The history of various types of vessels is covered under SHIP.)

This article is divided into the following sections:

I. MAIN ELEMENTS OF SEABORNE TRADE

While the volume of seaborne trade has been steadily increasing since the introduction of steam navigation, its nature and direction have been subject to changes. The main elements of seaborne trade are food and raw materials exported by primary producing countries and manufactured goods and capital plant exported by industrial countries in exchange. The shipping industry exists to enable these goods to be interchanged, but the greater part of the cargoes carried by merchant ships consists of basic raw materials (such as coal, oil, mineral ores, and fertilizers) and foodstuffs (particularly grain, sugar, rice, vegetable oils, fruit, meat, and dairy produce).

The growth of the world's population and the expansion of industrial development continue to make additional demands on the shipping industry. The process is best illustrated by taking the development of British trade and shipping. The invention of the steam engine led to a worldwide demand for British coal exports, which increased from about 11,000,000 tons in 1870 to as much as 73,000,000 tons in 1913, not taking into account an additional 21,000,000 tons shipped overseas for use as ships' bunkers. After World War I the growth of motor transport and the development of diesel engines for industry and transport caused a decline in the demand for exports of United Kingdom coal, which amounted to about 36,000,000 tons in 1938, in addition to 10,000,000 tons for bunkers. By the mid-1960s coal exports of all categories, including bunkers, had fallen to barely 6,000,000 tons. Meanwhile, of course, the importation of petroleum products had already assumed large-scale proportions. By the mid-1960s the United Kingdom was importing oil at the rate of more than 60,000,000 tons.

Another long-term development was the increase of the requirements of the steel industry. For many decades British steelworks were able to rely on domestic supplies of native iron ore, but in the first half of the 20th century they had to draw more and more on supplies from sources such as Sweden, France, North Africa, and Newfoundland. Demand for iron ore increased so rapidly after World War II that United Kingdom imports of iron ore rose from 11,500,000 tons in 1954 to about 15,000,000 tons in 1956, some of which had to be drawn from much more distant parts of the world, such as Venezuela, Brazil, and Liberia, so that there was an additional load to be accepted by the shipping industry. By 1964 this figure had reached 18,400,000 tons.

Parallel developments took place in the United States economy. Before World War II the United States was a prominent exporter of petroleum products to the rest of the world, but shortly after the war it became a net importer of oil. At the same time its coal export trade soared to new heights as a result of a deficiency of fuel in Western Europe. The steel industry expanded so rapidly that it, too, could no longer rely on supplies of domestic ore, and a vast expansion of imports from Labrador, South America, and Liberia began.

Technical and economic changes affect demands on the shipping industry, and basic trade routes are laid down according to the pattern of economic geography. It is the geographical position of sources of the principal commodities shipped and that of their main centres of consumption that chiefly shape the pattern of world shipping movements, although these are, of course, influenced by political and physical factors as well.

The chief grain-producing areas of the world, for example, are the United States and Canada, Australia, Argentina, the U.S.S.R., and France. India at one time was an exporter of wheat, but the growing population and rising standard of living of that part of the world have made India and Pakistan substantial importers of grain; much the same situation now applies to the countries under Soviet influence, and the exportable surplus of France as often as not becomes a deficit. There is a steady flow of grain from the three principal exporting areas—North America, Australia, and Argentina—to the continent of Europe and to Japan, as well as to most other countries in the world, but the largest importer of grain is the United Kingdom, as it is of most other foodstuffs. Britain's need for imported foodstuffs is indeed a staple element in seaborne trade, for it must rely on meat from Australia, New Zealand, Argentina, and Uruguay; on fruit from South Africa, Australia, New Zealand, the Mediterranean countries, the West Indies, and Central and North America; on dairy produce from Australia, New Zealand, and Denmark; and on perishables from the near continent, particularly from France, Belgium, and the Netherlands. Sugar comes mainly from Cuba, Mauritius, and Queensland (Australia), which are the main exporters of this commodity to the rest of the world.

Of the sources of energy, oil is steadily surpassing coal in volume, but after World War II coal was a staple export from the United States to Western Europe, mainly to Italy, France, and the Federal Republic of Germany, to Japan, and to South America. The main oil-exporting centres after World War II were the Middle East (Iraq, Iran, Kuwait, Saudi Arabia, Bahrain, and other neighbouring oil fields) and Venezuela and the Caribbean area. The Soviet Union and the United States are prolific producers, but mainly for domestic consumption. Thus oil from the Middle East flows to all parts of the world, the principal consumers being the United Kingdom and Western Europe, with increasing consumption in India, Africa, and the Far East, the United States, South America, and Australia.

Of industrial raw materials, mineral ores became predominant after World War II. The steel industries of the United States, the United Kingdom, the Federal Republic of Germany, and Japan are the greatest consumers of iron ore, which is imported from Labrador, West and North Africa, India, Sweden (as a rule through Norwegian ports), Venezuela, and other parts of South America. Copper is imported by the major industrial countries chiefly from Rhodesia and Chile; tin from Malaya and Bolivia; lead and zinc from Australia. Bauxite, or alumina, the raw material for the production of aluminum, flows mainly from the Caribbean to the United States and Canada, and from West Africa and the south of France to the United Kingdom, Norway, and other European producers. The produced metal is exported by Canada and the United States in ingot form to other manufacturing countries, particularly Great Britain, from which the finished manufactured products may be exported to all parts of the world.

Besides the principal commodities in the seaborne trade mentioned above, many others are handled by the shipping industry in quantities exceeding 1,000,000 tons a year, and they include phosphates, iron and steel scrap, potash, nitrates and other fertilizers, pyrite, sulfur and sulfur compounds, basic slag, cement, rubber, wool, cotton, oilseeds and vegetable oils of various kinds, rice, and coffee. Other commodities, such as tea, jute, timber, tobacco, copra, salt, china clay, and chemicals, are also shipped by sea in large quantities, along with a great variety of shipments of manufactures, machinery, and processed goods.

II. SPECIALIZATION IN SHIPPING

It would be an oversimplification to suppose that international trade is mostly a two-way traffic between industrial manufacturing and primary producing countries, or even an interchange of manufactured goods between one country and another. Much of the world's trade is triangular in character, involving the shipment of raw materials from one country to another, where they are converted or processed for export to a third country. The rate and direction of flow of trade in various commodities, whether raw materials, foodstuffs, or manufactured goods, is subject to continual change, which calls for considerable flexibility in the employment of ships.

The different types of goods carried by sea require, moreover, a wide variety of types of ships, and it is the business of the shipping industry to provide such vessels. The growth of international trade has thus encouraged the development of some specialization in shipping, which has taken various forms, such as the provision of ships designed to carry certain cargoes or to participate in certain trades along well-established routes.

1. The Liner and the Tramp.—The two main branches of the shipping industry are the liner business and tramping. The essential difference between the liner and the tramp is that the former operates regular scheduled services on a predetermined trade route, whereas the tramp is prepared to carry any suitable cargo from any part of the world to any other part of the world. The liner services are the railways of the oceans, running regular services at stated times between scheduled ports, and charging previously advertised tariff rates. The tramps are more like taxicabs or road transport operators, which may ply for hire or will contract to transport goods between any required ports, the terms being arranged by negotiation between the parties on each occasion, or on a contract basis. The tramp system had its origin in the days when it was customary for the master to be owner, or at least part owner, of his own ship. He would load it with a cargo of goods which he hoped to sell in some foreign country, and use the proceeds to buy a cargo which he could sell in another country

or for which he could find a ready market at home.

As more regular trade developed between two overseas countries, such as that between the United States and the United Kingdom, and with the advent of steam navigation, which gave greater assurance of regularity of communications, the steam navigation companies began to operate liner services. The liner services were, and still are, of particular value for passengers and mails, and for small traders not dealing in commodities normally consigned in shiploads. The shipper of commodities in bulk, such as grain or coal, naturally found it more economical to hire ships on the open market, offering his business of transportation to the lowest bidder, or buying and selling his commodity in the market where sea transport costs were for the time being cheapest. Thus the tendency is for tramp ships to be the carriers of homogeneous cargoes of commodities in bulk, while liners are principally carriers of heterogeneous cargoes, made up of hundreds of small consignments of goods of many kinds, as well as mail and passengers.

There thus grew up what is now a worldwide network of liner services between the principal ports of the world. These services link the countries of Europe with the other continents, directly across the Atlantic to the eastern shores of North and South America, through the Panama Canal to the western shores of America, the Pacific Ocean, Australia, and New Zealand; directly to North, West, and South Africa and on to other parts of the world; or through the Suez Canal to East Africa, the Indian Ocean, the East Indies, and the Far East. They link the United States in addition directly, or through the Suez and Panama canals, with Europe, South America, Africa, and the countries of the Indian and Pacific oceans. They link Japan with Africa and America, India with Africa, China with India, and, finally, by transshipment to coastal liner services they provide sea communications between practically all the seaports of the world.

The bulk cargoes carried by tramp ships also tend to flow in volume along regular routes from time to time, and where these coincide with regular liner services the liners will periodically pick up "parcels" of these commodities, particularly grain, but usually only in order to fill up holds that otherwise would be empty.

2. Various Types of Cargoes.—The principal bulk cargoes have varying characteristics (liquid cargoes are in a category apart requiring specially designed ships and must be considered as a separate branch of the shipping industry). The normal dry-cargo tramp ship is adaptable in design, so that it is capable of carrying, as occasion arises, cargoes as different as iron ore, coal, grain, sugar, cotton, or copra. Each of these cargoes has different characteristics. Because of the difference in stowage factors (cubic capacity per ton), for example, a ship large enough to carry 10,000 tons of coal might be loaded down to its maximum draft with less than 5,000 tons of ore, and if it were to carry grain, "shifting boards" would be necessary in the holds to prevent the cargo upsetting the stability of the ship by pouring over to one side when the ship rolled.

Different methods are used for loading and discharging different types of cargo. Cargoes shipped in cases, bales, or bags must be handled by the ship's derricks or by shore cranes, and the same applies to cargoes of commodities like timber, steel, or scrap. Iron ore and coal are discharged by grab, and grain by elevators or suction pipes.

3. Specialized Carriers.—Where any one commodity is carried in large quantities over regular routes, it becomes an economic advantage to build ships specially suited to the cargo concerned, and because of the vast expansion of world trade in bulk commodities the tendency is for specialized bulk-cargo carriers to be built. The specialized ore carrier is a typical example. Large numbers of these have been built since World War II, although they were in operation on the Great Lakes at the end of the 19th century. They rely entirely on shore appliances for cargo handling, not being provided with derricks, although some ore carriers designed for service to ports where shore-handling facilities do not exist are equipped with self-unloading gear. These, of course, are ultra-specialized.

Specialized ships such as ore carriers may still be divided into the two categories of liner and tramp, in that some of them are built by companies owning tramp ships with the object of their being hired out, or chartered, to the shippers or importers of ore, usually on a long-term basis, while others are built and operated by the shippers or consumers of ore themselves, mainly the large steelworks. The latter vessels are liners in the sense that they are designed for and operate on regular routes between predetermined terminals, but they do not operate as common carriers and accordingly are better called industrial carriers. Several other industrial consumers of raw materials in bulk, such as major importers of sugar, newsprint, molasses, gypsum, and chemicals, operate their own fleets of bulk carriers in a similar fashion, as well as hiring ships from tramp shipowners on the open market.

4. Tankers.—The transport of petroleum products by sea is a special branch of the shipping industry which has witnessed a vast expansion in the 20th century, particularly after World War II. Some indication of the rate of expansion is given by comparison of world tanker tonnage in 1939 and 1964. In 1939 the world tanker fleet totaled 11,586,000 tons gross, comprising 16.9% of the total tonnage of all merchant ships. By June 1964 the tanker fleet had reached a total of 50,563,000 tons gross, representing as much as 33% of the total world fleet then in existence. Measured in terms of dead-weight tonnage the world tanker fleet rose from 16,000,000 tons in 1939 to more than 23,000,000 tons in 1946; yet the 1946 figure had been more than tripled by the mid-1960s.

Liquid cargoes such as crude oil or gasoline need ships heavily subdivided into compartments in order to restrict the movement of the free surface derived from the motion of the ship at sea which would otherwise upset the stability of the vessel. No shipborne cargo-handling facilities such as derricks or cranes are required, since the oil is pumped on board through pipelines at the oil terminals and discharged through pipelines by means of the ship's own pumping system at ports of destination. Owing to the inflammable nature of the cargo, special precautions must be taken against the risk of fire. Before World War II the greater part of the world tanker fleet was owned and operated by the major oil companies, operating as industrial carriers, but they depended for their marginal requirements on the chartering of tramp tankers.

After World War II, despite the expansion of their own fleets, the oil companies had to rely to a much greater extent for their ocean transport on tankers operated by tramp companies, generally on a long-term time-charter contract basis. A particular feature of the tanker trade is that it is almost entirely a one-way traffic, and since tankers are not suitable for carrying any other type of cargo without structural alteration, the outward journey must be made in ballast. An exception is made for iron ore, which has a low stowage factor. Sweden, an ore-exporting and oil-importing country, evolved a ship capable of carrying an inward cargo of oil and an outward cargo of ore. As a result of the exploitation of the Labrador ore fields, this combined oil and ore carrier was increasingly built after World War II. In the winter season the ore-loading ports of Labrador are closed by ice, so that these specially designed ships can find alternative employment as oil carriers in the off-season. Other liquid cargoes besides oil products may be carried in considerable bulk, and there are tankers used only for goods such as molasses, caustic soda and other chemicals, wine (and sometimes water), or for semiliquid cargoes such as asphalt and bitumen, and even petroleum gas in liquid form.

5. Coastal and Short-Sea Shipping.—Most of the oceangoing types of ship have their counterpart on a smaller scale in the coastal shipping industry, whose function and extent naturally varies in different parts of the world according to geographical conditions. Coastal shipping (sometimes referred to as cabotage) is another branch of the shipping industry, since its services are generally confined to the coastal waters of a particular country. In countries with continental coast lines, such as the United States, Australia, and India, for example, coastal shipping may not differ operationally from oceangoing shipping, and in the United States the term is extended to include the intercoastal trades between the Pacific and Atlantic coasts via the Panama Canal, and the noncontiguous trades between continental America and outlying

areas such as Hawaii. In Europe, where national coastlines are comparatively short, and the restriction of coastal trades to ships of the national flag is not generally practised, coastal shipping has a more international character.

In the United Kingdom, for example, there can be distinguished the purely coasting trade, plying solely among the islands and along the coast of Great Britain; the home trades, which ply between the United Kingdom and the continent of Europe within the limits of Brest, in France, and the Elbe, in Germany; and the short-sea trades, between the United Kingdom and Scandinavia, the Baltic Sea and the Mediterranean. Some shipping companies, of liners, tramps, or tankers, may operate in all of these trades, while others may specialize in any one.

In the coasting and short-sea trades there are also many specialized vessels such as cross-channel passenger ships, train ferries, ramp-loading or roll-on roll-off motor vehicle transports, ships specially designed for container traffic and the like, as well as colliers and tankers. These tend to be operated by companies specializing in particular routes over which traffic is heavy but localized. As these services often form sea links between or extensions of railway systems, the railway companies often operate them. In fact, the coastal shipping industry may be regarded as complementary to the inland system of transport communications, as well as a link with neighbouring countries; and a most useful characteristic of the coastal ship is its ability to load cargo directly from the oceangoing vessel for transshipment along the coast and distribution to smaller ports whose depth of water or lack of facilities precludes the direct approach of the larger ship.

6. Inland Waterways.—The shipping industry also includes transport services along rivers and inland waterways. Vast quantities of materials are shipped along waterway systems such as those of the Mississippi, the Amazon, the Niger, and the Rhine, sometimes penetrating thousands of miles into the heart of a continent.

See WATER TRANSPORT, INLAND.

7. Ancillary Services.—At the port, where the sea transport and inland transport systems meet, many ancillary services must be provided for ships, such as towage, stevedoring, warehousing, replenishment of stores, repair, and maintenance. At this point industrial practice varies widely between different ports, the various services being provided by independent contractors, by the port authority, or by the shipping companies themselves. In many ports, particularly where large liner companies operate, the companies have their own subsidiary organizations which provide such services, not only for their own ships but also for others. Some of the larger shipping groups operate or control fleets of tugs, loading and discharging facilities and labour, warehouses and refrigerated stores, lighterage and land transport, and even provide for the building, repairing, equipment, and maintenance of ships for themselves and for other shipowners.

Inland waterways and seaports must be kept clear by dredges, and in northern waters which freeze in winter icebreakers must be used to clear shipping lanes; salvage services must be provided for clearing wrecks and other obstructions to navigation and for rescuing ships which have broken down; and cable ships must be provided to maintain telegraphic communications between all parts of the world. All these maritime services, essential to the operation of international seaborne trade, are part of the shipping industry. However, the fishing industry, including whaling, may be regarded as a separate maritime activity unconnected with the commercial operation of merchant ships. *See* FISHERIES; WHALING.

III. SHIP OPERATION

The essential differences between the liner and tramp sections of the shipping industry, namely in the kind of transport service they perform, have been described above. As the carrying performances of liners and tramps differ, so do the operational organization and methods of the companies that run them.

1. Liner Operation.—The growth of liner services resulted from the introduction of steam navigation, which enabled ships to maintain regular services at predictable intervals, mechanically propelled ships being much less dependent than sailing ships on the vagaries of wind and tide. A sailing ship, wherever bound, did not ordinarily sail, either with general merchandise or a bulk cargo, until its holds were full. Sailing dates were therefore uncertain, and arrival dates even more so. The merchant was obliged to ship his goods in speculative anticipation of the state of the market at the time of their arrival at destination, and shippers of small consignments or parcels of cargo were even more uncertain of being able to deliver at a specified time. Fast sailing ships (such as those of the American Black Ball Line) were actually the first to attempt regular liner services across the North Atlantic early in the 19th century, but it was not until the coming of the steamship that such services became firmly established.

The possibility, with liner steamships, of regular sailings from a wider range of loading and discharging ports, with a guarantee that ships would sail whether full or not, and the development of more reliable postal, and, later, telegraphic communications, allowed much more international business to be done, particularly by traders wishing to send small consignments of goods to various destinations at frequent intervals or even only occasionally. Thus liner cargoes are usually composed of a wide variety of general merchandise, of differing values, nature, and quantity, including material that does not customarily move in shipload lots along the trade route concerned. The first modern liner services naturally followed the direction of the greatest demand. The Cunard Line started the first regular steamship liner services from Great Britain to the United States in 1840, and in the same year the Peninsular and Oriental Steam Navigation Company began a liner service from Britain to the Mediterranean area. In 1842 the Royal Mail Steam Packet Company (now Royal Mail Lines) started a regular steam packet service from Britain to the West Indies, with the aid of a government mail subsidy.

The operator of a liner service has special interests in the particular trade route for which he caters. The design and performance of his ships will be directed toward fulfilling in the most economical way possible the requirements of shippers using his services. Some liner routes, such as those between the United Kingdom and Australia and New Zealand, have to cater for a large proportion of refrigerated cargoes such as meat and dairy produce, as well as wool and parcels of grain or base metals, in the direction of Great Britain, and for machinery and motor vehicles and other manufactured goods in the opposite direction. The requirements of liner trades on any particular route range widely in character and fluctuate in quantity. They are apt to be shipped by numerous individual exporters and consigned to no less numerous individual consignees. The collection of such consignments and their assembly into the ship at the loading port, or ports, and their distribution at the ports of discharge obviously require an extensive, permanent organization at each end of the liner route; and the liner company must have staff and offices at the ports that it serves, although in some of the less active ports these functions may be carried out by agents acting for one or more liner companies. Besides this, the services of forwarding agents or travel agents must be employed for soliciting cargo or passengers from inland centres sometimes far removed from the ports of shipment, and it must always be possible to arrange for the transshipment or onward movement of cargo and passengers from terminal ports to eventual destination.

2. The Conference System.—Not only do the liner companies provide regular and frequent services between different parts of the world for the carriage of every conceivable kind of cargo in consignments large and small, but they are prepared to do so at previously advertised fixed charges. They are enabled to do this by means of the liner conference system, which first began to be practised in the United Kingdom-Calcutta trade in 1875. The object of the conference system is to regulate uneconomic competition. The shipping companies of different ownership and nationality that operate services between the same range of ports form a conference agreement to regulate the freight rates that they will charge for each type of goods carried; and in some cases the agreement also allocates a specified number of sailings to each company. Coupled with this agreement there is generally a de-

ferred rebate system, by which regular shippers of goods by conference vessels receive a rebate of a percentage of the tariff freight rate, payable after a period of proved loyalty, provided they use conference vessels exclusively.

The shipping conference system has sometimes come under attack as tending to create monopolies and to restrict competition against the public interest. After investigations, however, the evidence has weighed in favour of the conference system (which in the United States is subject to regulation and approval by the Maritime Administration). It has been felt that no combination of shipping companies can force unreasonable freight rates on shippers, since under those circumstances an outside company will step in to provide a genuine service at reasonable rates; and, on the other hand, shipping companies that provide regular sailings with good ships and maintain staffs and organizations in ports to handle and dispatch cargoes, irrespective of whether trade is good or bad, are entitled to some protection against the casual ship that picks up an occasional cargo at cut rates. It is to the advantage of the shipper that through this system he can rely on a well-managed service, running ships that will carry any desired quantities of his goods at predetermined rates, and that these rates are not usually changed without at least three months' notice.

3. Tramp Operation.—Unlike liners, tramp ships do not provide scheduled sailings between predetermined ports, and they are generally used solely for the carriage of bulk commodities, or homogeneous cargoes, in whole shiploads. There is no fixed tariff of freight rates and no conference system. Every voyage of a tramp ship is the subject of a separate negotiation between the owner of the ship and the owner of the cargo, and its terms are generally arranged through a ship broker in one of the shipping exchanges located in various parts of the world, but mainly in London and New York.

4. Brokerage and Chartering.—Most of the world's tramp ship chartering business is carried out in the Baltic Mercantile and Shipping Exchange, Ltd., in London, commonly known as the Baltic. This exchange had its origins in the 17th century, when merchants and ships' captains were accustomed to meet in coffeehouses (the most famous of which was Lloyd's) to arrange cargoes for ships. The Baltic and the Jerusalem were the two coffeehouses chiefly patronized by merchants and captains until the business was moved to the Baltic tavern in 1810. In 1823 the first rules and regulations of a "Baltic Club" were drawn up, limiting membership to 300 and providing for accommodation and refreshments. At that time tallow was the principal commodity in the Baltic trades, but with the repeal of the Corn Laws in 1846 the buying and selling of grain cargoes became one of the chief activities and called for larger premises. In 1856 larger premises were taken in South Sea House and two years later membership had doubled.

The opening of the Suez Canal and the growth of steam navigation caused a further expansion of trade and in 1903 the Baltic Exchange in its present form was opened in an entirely new building. After World War II air chartering was added to the exchange's activities, and in 1956 a new building was opened as an extension to the 1903 structure, doubling its size.

On the floor of the Baltic Exchange brokers circulate daily, some of them representing the shippers of cargoes such as grain, coal, or ores who require shipping space for their movement, and others representing the owners of tramp ships wanting further employment. When seeking a ship for the carriage of a cargo, the broker naturally looks out for a ship of the right size and specifications, ready at the right time and in the right port, and prepared to carry the cargo at the cheapest possible rate. Conversely, the owner's broker must attempt to anticipate the charterers' requirements by having his ship at the right place at the right time, but he must also try to obtain the highest freight rate possible without running the risk of losing the contract to a competitor. This constant interplay of supply and demand, of ships as well as of cargoes, has the effect of reducing sea transport costs to a minimum, although tramp freight rates fluctuate frequently and widely at times.

These conditions of fluctuating rates also offer opportunities for speculation, as on a stock exchange. The shipper of grain, for example, may decide to charter a ship at what he considers to be a cheap rate even before he has sold the cargo, which he will attempt to dispose of in the best market while it is still afloat. In this case the ship will be chartered for a voyage from, say, the Río de la Plata to the English Channel "for orders," freight rates having been previously arranged to cover a variety of alternative eventual destinations. Again a shipper or an owner may agree to charter a ship for a period of time at a certain rate, in the hope that he will later be able to "relet" it to another owner or shipper at a higher rate, if the market improves. A good deal of "forward" chartering may also occur, in which a contract is entered into for performance at some specified time at a predetermined rate that both owner and hirer hope will prove favourable, according to their view of future market conditions.

5. Methods of Chartering.—There are four principal methods of chartering a tramp ship—on voyage charter, on time charter, on bareboat charter, or on a contract or "lump sum" basis. The voyage charter is the commonest. Under this method a ship is chartered for a one-way voyage between specified ports with a specified cargo at a negotiated rate of freight. The charterer agrees to provide the cargo for loading at the port or ports and the owner to present the ship for loading within an agreed range of dates. As soon as the cargo has been delivered at the port or ports of destination, the ship is free for further employment at the owner's discretion. Sometimes, however, the arrangement is for a series of consecutive voyages, generally for similar cargoes over the same route. The freight rate is expressed in terms of so much per ton of cargo delivered.

On time charter, the charterer undertakes to hire the ship for a stated period of time, or for a specified round trip voyage or occasionally for a stated one-way voyage, the rate of hire being expressed in terms of so much per ton deadweight per month (*see* below for meaning of tonnage measurement). Whereas on a voyage charter the owner bears all the expenses of the voyage (subject to agreement about costs of loading and discharging), on time charter the charterer bears the cost of bunkers and stores consumed.

On bareboat charter, which is less frequently used in ordinary commercial practice, the owner of the ship delivers it up to the charterer for the agreed period without crew, stores, insurance, or any other provision, and the charterer is responsible for running the ship as if it were his own for the period of the contract.

Contracts can also be arranged on a lump-sum basis, when an owner agrees to ship a given quantity of a stated cargo from one port to another for a stated overall sum of money. Sometimes large quantities of cargoes such as coal are arranged for on a contract basis. The shipowner agrees to undertake the shipment of a given quantity over a given period at a fixed price per ton of cargo, but not necessarily in any specified ship, although he will generally use his own ships if they are available, unless he can subsequently charter other ships at a cheaper rate. The question of substituted ships, however, often leads to disputes and the terms of the contract may make special provisions for this eventuality.

6. Legal Aspects of Chartering.—Once the owner's broker and the charterer's broker have agreed on the terms of contract, the ship is "fixed," although by word of mouth alone. The proud motto of the Baltic Exchange is "our word is our bond," and that code of ethics is observed by ship brokers throughout the world, whether they are members of the Baltic or not, for the simple reason that any ship broker who did not abide by it would be unable to transact further business. Legally, however, the final contract is the written "charter party," which for most transactions is accepted as a standard document and is agreed to by all parties normally concerned in a tramp ship "fixture" for a particular trade. The standard form of charter party covers all the main points which experience has shown might later lead to misunderstanding or disputes about the liabilities of each party, while the variable details, such as the particulars of the voyage, cargo, ship, loading and discharging conditions, and ports, rate of freight, etc., can be inserted in accordance with the prior verbal agreement. The

charter party is the document that is subject to scrutiny and interpretation by a court of law in the event of dispute, but in practice most disputes are by agreement submitted to arbitrators (generally independent ship brokers appointed by each participant) for settlement, unless an important legal precedent is involved.

Among the most important clauses in any charter party are generally those which lay down the number of days allowed for loading or unloading, and those which determine who is to bear the expenses involved. As a rule, a certain number of days are allowed for loading, and if the charterer fails to finish loading in the time specified the shipowner is entitled to compensation for demurrage, while the charterer, on the other hand, is entitled to dispatch money if the cargo is loaded in less than the time agreed in the charter party. Similar conditions usually apply in the port of discharge.

Tankers, ore carriers, and other industrial carriers operate either like dry cargo liners or like tramps, except that on scheduled services they do not normally act as common carriers. In other words the tanker or the ore carrier is operated by an oil company or a steel company or an ore exporter exclusively on company business, whether on a regular schedule or not; or it is owned by an independent tramp shipowner and taken on charter by an oil or steel company to fulfill its marginal transport requirements on terms similar to those employed in the dry-cargo tramp shipping market. That is, perhaps, a simplification of the procedure, since in fact the oil company may, for example, find it convenient to charter its own ship to another oil company for a voyage or for a period of time, just as a tramp shipowner might do. Most of the major oil companies (and permanent large shippers of bulk commodities) build and operate for themselves fleets of ocean carriers—and their operation is a matter of company convenience, requiring no contractual obligations or other arrangements except suitable shore staffs and organizations or agencies at the terminals. The great expansion of oil transport requirements after World War II led to a rapid growth of the world tanker fleet, and capital commitments made it more than ever necessary for oil companies to rely on the tankers built and operated by the growing number of independent tank shipowners.

IV. INTERNATIONAL MARITIME LAW

1. The International Conventions.—Ships operate in an international field, the high seas, and are subject not only to the laws of the country in which they are registered and to the laws of the country in whose territorial waters they may be, but also to a series of international conventions, the principles of which are incorporated into the domestic legislation of most maritime countries. There has grown up, particularly in the years since the expansion of steam navigation, a body of international maritime law—"the common law of the sea"—which has been developed through international agreement. For example, nearly all the world's maritime nations have adopted the International Rules for the Prevention of Collision at Sea, which were originally based on British rules formulated in 1862 and made internationally effective after a series of international meetings culminating in a conference at Washington, D.C., in 1889. These rules lay down in great detail how ships must navigate in respect of each other, what lights must be shown and what signals must be given in accordance with circumstances; any infringement of this international code of conduct is accepted in all maritime courts of law as prima facie evidence of liability in case of collision.

Similarly, the internationally accepted requirements for the protection and safety of life at sea, as far as the ship and its equipment are concerned, are embodied in the International Convention for the Safety of Life at Sea. The sinking of the "Titanic" in 1912 gave rise to a general desire to raise the standards of safety of life at sea, and a convention was drawn up in 1914 requiring certain minimum standards for passenger ships; however, this did not become fully operative owing to World War I. A second Safety of Life at Sea Convention was drawn up in 1929; this decided minimum standards for the construction of passenger ships engaged in international voyages and for the provision of lifesaving appliances, and extended its rules for the safety of navigation to all ships on all voyages. The provisions regarding radio equipment were extended to cover cargo ships of more than 1,600 tons gross.

Improved techniques led to the convening of a third Safety of Life at Sea Conference in London in 1948, after which a third International Convention on the Safety of Life at Sea was adopted. This came into force on Nov. 19, 1952, having been ratified one year previously by the following countries in order of acceptance: United Kingdom, New Zealand, the United States, France, the Netherlands, Sweden, Norway, South Africa, Iceland, Portugal, Canada, Pakistan, Denmark, Yugoslavia, Italy, Belgium, Israel, Japan, and the Philippines. The scope of the 1929 convention was again extended to include, in several matters, cargo ships of 500 tons gross and above. Minimum requirements were laid down for the construction of ships, for the provision of watertight bulkheads, for the closing of openings in hulls for lifesaving appliances, for fire appliances, for radio equipment and direction finders, for grain divisions in ships carrying grain cargoes, for the carriage of dangerous goods, and for emergency musters and drills. The 1952 convention also embodied the recommendations of governments associated with the World Meteorological Organization, and provided for the continuance of the International Ice Patrol maintained by the United States Coast Guard in the North Atlantic. This convention was again revised in 1960.

Whereas the Safety of Life at Sea Convention deals with the construction of ships from the safety point of view, particularly in respect of passengers and crews, the International Load Line Convention deals with the strength and seaworthiness of ships in normal operating conditions. This convention emerged from the efforts of Samuel Plimsoll, who succeeded in securing the passage of the British Merchant Shipping Act in 1875. This act provided for the marking of a load line, thereafter popularly known as a Plimsoll mark, on the ship's side, indicating the maximum depth to which a ship could legally be loaded.

In order to protect the competitive position of British ships, the Merchant Shipping Act of 1890 required all foreign ships leaving British ports to comply with the load line regulations. This led to the adoption of the load line rules by most maritime countries, and the International Load Line Convention of 1930 was ratified by 54 nations. The 1930 rules followed the British proposals closely, but provided for the deeper loading of tankers, of ships of special construction, and of vessels carrying deck loads of timber. Provision was also made for the adjustment of load lines to suit seasonal and geographical variations in conditions.

In 1958 the Inter-Governmental Maritime Consultative Organization (IMCO) (*q.v.*), a specialized agency of the United Nations, came into existence. The purpose of this organization, which is advisory in nature, is to promote international cooperation in maritime navigation. By the end of 1960, membership in IMCO had grown to 44 nations. The Maritime Safety Committee of IMCO approved the organizational arrangements for the 1960 Safety of Life at Sea Conference.

2. Commercial Legislation.—International agreements and international law are also concerned with the business dealings between maritime countries. In this connection the International Maritime Committee (Comité International Maritime) and the International Law Association did invaluable work. Delegates to the International Conference on Maritime Law held at Brussels in 1922 recommended to their respective governments the adoption of a set of rules, known as The Hague Rules, which establish the responsibilities, rights, and immunities of carriers under bills of lading (documents acknowledging receipt of cargo for shipment and proving entitlement to the goods). The Hague Rules, which are generally also incorporated into the terms of a charter party, were given widespread legislative sanction by maritime countries, in Britain by the Carriage of Goods by Sea Act, 1924, and in the United States by the Carriage of Goods by Sea Act, 1936, which is also taken in conjunction with the Harter Act, 1893. Legislative sanction is not necessary to secure international agreement or observance in every case.

The York-Antwerp Rules of General Average, for example,

differ in some respects from English law relating to marine insurance and contracts of affreightment. They were formulated by delegates from various maritime countries meeting at York, Eng., in 1864 and at Antwerp in 1877, and were revised at Stockholm in 1924 and at Amsterdam in 1950. They were so widely adopted by the maritime nations that for all practical purposes they have the force of law. *See* MARINE INSURANCE.

V. SHIPOWNERS' AND SEAMEN'S ASSOCIATIONS

Shipowners themselves are generally organized on a national, and sometimes on a regional, basis. The most highly organized associations of this kind grew up in the United Kingdom, where all but a negligible minority of shipowners are members either of the Chamber of Shipping of the United Kingdom, based in London, or the Liverpool Steam Ship Owners' Association. These two associations have sections which look after the special interests of subgroups in the industry, such as tankers, tramps, liners, coasters, etc. In order to speak with one voice in negotiations with the government on matters of highest policy, the two associations created a joint organization known as the General Council of British Shipping. These organizations speak for shipowners as a whole in regard to many industrial matters, such as pilotage and towage agreements and contracts, port organization, dock labour, and national legislation, and to settle countless points at which external matters touch the maritime industries. Associations in other countries often also undertake wage negotiations with seafarers; the British associations, however, do not. Wage negotiations are handled by a separate organization known as the Shipping Federation, which was formed early in the 20th century in order to combat the activities of the newly created National Union of Seamen. Wage negotiations in the British mercantile marine since World War I have been conducted entirely through the medium of the National Maritime Board, which consists of representatives of the Shipping Federation on the one side and representatives of the seafarers' and officers' unions on the other. The work of the National Maritime Board extends, in addition, to the associated subjects of manning scales, hours and conditions of work, and standards of accommodation, etc., as well as to such matters as sickness benefits, pensions, and contracts of employment. Since 1947 it has been possible for British officers and seamen to enter either into individual service contracts with shipping companies, or into a general service agreement with the industry as a whole which guarantees a minimum wage for a minimum period of two years, whether or not the seafarer is in employment, provided that he undertakes to serve in any British ship to which he may be posted. (*See* also LABOUR LAW: *England*.)

On the international level, the national shipowners' associations are members of the International Chamber of Shipping, provided that the national industries concerned are not state controlled. This organization, whose offices and secretariat are housed at the London headquarters of the Chamber of Shipping of the United Kingdom, was formed before World War II, and excluded state shipping organizations of any kind. The ownership of the national fleet, or of a substantial part of it, had to be vested in private individuals or companies. The International Chamber of Shipping was suspended during World War II but in 1946 shipowners representing 14 nations (Australia, Belgium, Canada, Denmark, Finland, Greece, India, the Netherlands, New Zealand, Norway, Spain, Sweden, the United States, and the United Kingdom) met in London to reconstitute it. The assembly wished to avoid the overlap of its functions with those of other organizations and, "bearing in mind the vital need for preserving the principles of private enterprise in a complex industry which must essentially operate in an international sphere," drew up a broad definition of its own purposes as follows:

1. To promote internationally the interests of the shipping industry on all matters of general interest not already dealt with by other specialized organizations within the industry.
2. To coordinate expert advice within the industry in regard to technical questions affecting it and, in particular, with a view to securing improvements in standards of safety and the fullest advantage of technical and scientific progress. In this connection it will be necessary at the outset to consider the procedure which should be followed in the light of postwar circumstances and in relation to government activities in this field.
3. To provide a medium for the exchange of views and information on questions affecting the industry internationally.

To deal with matters of a more routine nature other international shipping organizations exist. Prominent among these is the Baltic and International Maritime Conference, which was started in 1905 as the Baltic and White Sea Conference, in Copenhagen, with the object of putting a stop to the cutthroat competition which then existed between tramp shipowners engaged in the Baltic and White sea trades. The conference was organized primarily to secure minimum freight rates and arrange uniform chartering terms among shipowners of different flags. By 1955 the Baltic and International Maritime Conference consisted of shipowner and ship broker members from 35 different countries representing some 17,000,000 tons gross of tramp shipping. The conference now embraces many kinds of trades in all parts of the world, and one of its principal functions is to inform members of changes in port expenses, in costs of loading and discharging cargoes, and in labour conditions in ports; but perhaps the most valuable part of its work consists of the drawing up of standard forms of charter party for use in a wide variety of tramp shipping trades, and of securing acceptance for them. Most of this work is carried out in cooperation with the Documentary Committee of the Chamber of Shipping of the United Kingdom.

VI. CLASSIFICATION AND TONNAGE MEASUREMENT

1. Classification.—To ensure compliance with the various international safety and load line and other maritime conventions, as well as with the requirements of national legislation concerning the registry and construction of merchant ships, most maritime nations require ships to be built under the supervision of government surveyors or of surveyors belonging to recognized classification societies and in accordance with their standards.

Lloyd's Register.—The leading classification society, operating in almost every country in the world, is Lloyd's Register of Shipping, which began its work long before any national legislation existed for the performance of its purposes. The history of Lloyd's Register of Shipping can be traced back to 1760 (*see* LLOYD'S REGISTER OF SHIPPING). The society was reconstituted in 1834 and again in 1914. The shipping community maintains it voluntarily and its principal work is the supervision of the survey and classification of merchant ships of all nationalities according to rigid standards. Through a worldwide organization of surveyors, initial classifications are made when ships are built, and maintenance surveys of hull, machinery, boilers, refrigerating plant, etc., are carried out periodically or whenever the ship has suffered damage from collision or from any other cause. Lloyd's Register surveyors test and approve, during its manufacture, the steel intended for use in the ship's structure or for its engines and boilers; they survey refrigerating machinery at sea or on land; they supervise the testing of chains, anchors, and pressure vessels, and they are competent authorities for the assignment of freeboard to all classes of ship in accordance with the provisions of merchant shipping acts or the load line regulations.

The society publishes annually a register book which contains in several volumes full details of all merchant ships in the world of more than 100 tons gross; this is kept up-to-date by means of fortnightly supplements. Separate registers are kept of British and American yachts. The society also publishes annual and quarterly statistical summaries of shipping registered or under construction in the world. In 1949 Lloyd's Register of Shipping took into amalgamation the British Corporation for the Survey and Registry of Shipping, a similar organization founded by shipowners in Glasgow in 1890 as a rival classification society.

Lloyd's Register of Shipping operates in most maritime countries, often in cooperation with classification societies established by other nations. These include the American Bureau of Shipping, originally established in 1867, and resuscitated as a result of the large volume of merchant ships built in the United States during World Wars I and II; the Bureau Veritas, which was founded

in Antwerp in 1828 but moved its headquarters to Paris in 1832; the Norske Veritas, established in Norway in 1894; Germanischer Lloyd, founded in Germany in 1867; and Registro Italiano Navale, originally founded in Italy in 1861. Most of these and other national classification societies work in close conjunction with Lloyd's Register of Shipping.

2. Tonnage Measurement.—Classification societies are largely agreed as to the strength requirements of different types of ship, and the technical, legal, or commercial enactments of the conventions are almost universally accepted; however, complete international agreement on methods of tonnage measurement was slow to develop. The two chief reasons for this were, first the possibility of interpreting the term tonnage in several senses, and secondly the fact that a ship's tonnage is calculated by one of several methods according to the standard of measurement required. In speaking of shipping, the term ton may be used not only to name a unit of weight, in the usually accepted sense, but also to name a unit of volumetric capacity.

Displacement Tonnage and Deadweight Tonnage.—As far as weight is concerned, the ton is the long ton of 2,240 lb. avoirdupois, and this is used to measure the weight of the ship and its contents. According to the law of Archimedes, the weight of a floating vessel and its contents is equal to the weight of water that it displaces. This weight is known as the displacement tonnage, and the term is used most commonly in comparing the size of warships. In a cargo-carrying ship it is obvious that the displacement varies according to the amount of cargo, bunkers, and stores that are in the ship, and as it is important to determine the amount of cargo that can be carried, the ship's displacement must be calculated both when it is in light condition and when it is loaded, to find the difference which represents the weight of cargo that can be carried. The lightweight displacement tonnage is equivalent to the weight of water displaced by the ship's hull, machinery, and equipment, plus the weight of the crew and their effects, when no cargo or bunkers are carried. When the maximum permissible weight of bunkers and cargo is added, the ship has reached its full displacement tonnage. The difference between the full displacement tonnage and the lightweight displacement tonnage is called the deadweight tonnage, and this corresponds to the weight of cargo and bunkers the ship can carry. Deadweight tonnage is the measurement ordinarily used to describe and compare the sizes of dry-cargo ships and tankers.

Many procedures, for example the assessment of harbour dues and canal transit dues, require the use of a different system of tonnage measurement, based on the volumetric ton. The volumetric ton is a measure of the capacity of the enclosed space in a ship, one ton equaling 100 cu.ft. (2.8 cu.m.) of enclosed space. The volume of the ship up to the tonnage deck (which is generally the uppermost continuous deck) excluding certain exempted spaces such as the double-bottom tanks, the steering-gear compartments, the galley, and other spaces not used for the carriage of cargo, is described as the underdeck tonnage, and is expressed in terms of tons of 100 cu.ft. The internal volume of tween-decks and deck erections used for the carriage of cargo is added to the underdeck tonnage to give what is called the gross tonnage, again in terms of tons of 100 cu.ft. In merchant shipping statistics the gross registered tonnage is usually given. It is also given for passenger ships, whose deadweight tonnage is relatively unimportant as a means of comparing them in size. For the purpose of assessing dues payable for port, canal, pilotage, lighthouse, and other services, the freight-earning capacity of the ship is usually accepted as the criterion of measurement, and this is commonly arrived at by deducting from the gross tonnage the space devoted exclusively to such items as machinery, bunkers, crew accommodation, and navigating quarters in order to calculate the net registered tonnage. It is apparent that the final tonnage measurement of a ship according to the volumetric reckoning depends much on the definition of the spaces exempted from computation for various reasons.

The British system of tonnage measurement is the one most used by maritime nations, but in certain areas, notably the Suez and Panama canals, there are different systems of measurement for the assessment of tonnage on which dues are payable, and all ships have to be specially measured for the assessment of their dues when passing through these areas.

For the purpose of assessing freight rates on cargo, yet another form of volumetric tonnage is employed, known as the measurement ton, which is equivalent to 40 cu.ft. of capacity. This term has no connection with the tonnage measurements used for registration and for the assessment of dues. It derives from the fact that the charge made for carrying cargo is normally based either on the weight of the cargo or on the amount of space it occupies. Freight rates cannot all be fairly assessed by weight alone. It is obvious that a ton of feathers would occupy a far greater amount of the ship's hold than a ton of coal, for example. Likewise a heavy item of machinery, although occupying much less space than a ton of coal, would prevent the extra space being used for the carriage of more cargo, for such a deadweight cargo would bring a ship down to its load line limits with much of the cubic capacity of its holds still unfilled. Hence liner freight-rate tariffs are generally expressed in terms of so much per ton weight or measurement, the measurement ton being the equivalent of 40 cu.ft. of capacity, and the rate paid being the higher of the two.

VII. INTERNATIONAL PROBLEMS

Despite the large measure of international agreement and cooperation which has been achieved in the shipping industry, particularly in the 20th century, there is still much competition between merchant fleets. Those of one nation compete among themselves, and international rivalries are also strong. The situation is complicated by the fact that merchant shipping has an economic and strategic as well as a commercial value for most maritime nations. They depend on merchant fleets for the survival of their military power—troops and supplies must be carried by sea, and so must food and industrial raw materials. Many maritime nations too, particularly island nations such as Great Britain and Japan, depend for their economic existence on imports of food and of raw materials for industry, as well as on a flow of exports sufficient to pay for these. All this depends on merchant shipping. Moreover, Great Britain, Japan, Norway, and many

means of direct subsidies to liners on specified essential trade routes. In France, Italy, India and Argentina, the state participates directly in the ownership of the larger liner organizations. Ships engaged in international trade, whatever their flag, all have similar expenses. They pay much the same for bunkers, for repairs and maintenance, for cargo handling, and for port dues, except insofar as flag discrimination may be practised. Crews' wages however, do differ among ships of different flags. Shipbuilding costs tend to vary widely from one country to another, but in general shipowners may build where they please. The payment of direct shipbuilding or operating subsidies, therefore, is not as objectionable to unsubsidized shipowners as is the reservation of cargoes to ships of a particular national flag, whether this rule is incorporated in trade agreements or written into legislation. In the United States, for example, after World War II, the shipment of gift cargoes under the Mutual Security Act and the cheap sale of surplus farm products were allowed only on condition that at least half the ships used were of the U.S. flag.

other maritime nations depend to a great extent for their economic well-being on the ability to balance their international trading accounts with the invisible exports represented by the earnings of their shipping industry.

Politics and strategy interfere with the ordinary business activities of the shipping industry in several ways. For internal political reasons, some states decide that the provision of shipping services shall be a state monopoly, but in practice this is difficult to achieve since a state's jurisdiction does not extend beyond territorial waters. Various practices observed from time to time, however, are designed to protect the domestic shipping industry and to discriminate against shipping of other flags. These discriminatory measures may be used to protect the shipping of the national flag, even if the ships are not state owned. Higher port dues may be charged to foreign ships, for example, or national-flag ships may be favoured. In bilateral trade agreements it is sometimes stipulated that a fixed proportion of the cargoes must be carried in ships of the national flag. A common method of assisting the domestic shipping industry is to reserve coastal shipping to ships of the national flag, a policy abandoned by Great Britain with the repeal of the Navigation Acts in 1850. This decision greatly assisted the expansion of the British mercantile marine, but several other nations, notably the United States, adopted the opposite attitude and strictly reserved coastal trade.

Another means of assisting the national shipping industry and of protecting it against economic competition is the payment to it of direct or indirect subsidies from the national exchequer. These subsidies may take many forms, varying from tax exemptions or preferential credit terms to direct subsidy of shipbuilding or of operating costs. In the United States, where shipbuilding costs and manning costs are much higher than in most maritime countries, the Merchant Marine Act of 1936 and its successors attempted to promote the use of U.S.-flag merchant ships by

Although operating costs are much the same for ships of all flags, profits are subject to the rates of taxation in different countries. If all ships paid the same taxes, the margin of profit for each company would depend largely on its efficiency. After World War II, heavy taxes combined with a sharp rise in shipbuilding prices to cause the registration of more and more shipping companies in countries such as Panama and Liberia, where taxation was low. Greek and American shipowners resorted in large numbers to registry under these so-called flags of convenience, which have subsequently varied in number and size with the changing demands of international trade. In 1964 about 20,000,000 gross tons were so registered.

VIII. WORLD MERCHANT FLEETS

Statistics of world merchant shipping tonnage are little more than estimates until the later years of the 19th century, when steamships began to oust sailing ships from predominance in world trade. The statistics given in Table I illustrate the decline of the sailing ship between 1886 and 1935, and the increase in the total tonnage of merchant shipping in the world, which rose from 21,508,000 tons gross in 1886 to 64,886,000 tons gross in 1935. By 1939, before the outbreak of World War II, the world total had reached 69,404,000 tons gross (*see* Table II) and despite the enormous losses suffered during the war (Table III) the world fleet had reached 80,292,000 tons by 1948. The growth continued so that by 1955 the total tonnage exceeded 100,000,000 tons gross for

the first time. By 1964 the world merchant fleet totaled 153,000,000 tons gross, one-third of which consisted of tankers.

A significant feature of the development of the world merchant fleet after 1920 was the growth of the number of ships propelled by diesel engines. Table IV illustrates the increase in the proportion of motor ships. A simultaneous development was the replacement of coal by oil as fuel for steamships, a movement which reached its peak just after World War II. By 1964 coal-burning ships still in existence accounted for only 2.6% of the total tonnage, and the number of coal-burning ships being built was negligible.

Source: *Lloyd's Register of Shipping.*

After World War II a vast increase in world tonnage took place. This was partly due to the existence of many ships in the United States defense emergency reserve fleet, but chiefly to the rapid increase in the demand for oil tankers (*see* Table V). The United States became a net importer of oil, while the United Kingdom and the continent of Europe also required sea transport for oil. The mid-1950s saw a rapid expansion of world industry, especially of the steel industry in the Federal Republic of Germany, in the United Kingdom, and in Japan. The United States, though its domestic supplies of iron ore were inadequate, likewise expanded its steel industry. These circumstances caused an even greater demand for merchant shipping.

Although the total gross tonnage of the world merchant fleets constantly increased, the actual number of ships remained more or less steady (*see* Table II) because the average new merchant ship was larger, especially after World War II. The average speed of ships also increased, although to what precise extent it is impossible to measure. Large ships tend to have higher speeds than small ones, however, and there can be no doubt that the ton-mile capacity of the world fleet after the end of World War II increased proportionately even more than the total gross tonnage.

1. **British Commonwealth.**—As a result of British war losses and of the U.S. emergency shipbuilding programs of World Wars I and II, the mechanically propelled tonnage registered in the United States on two occasions exceeded that registered under the British flag. Great Britain nevertheless retained the largest active merchant fleet in the world, although its proportion of the world total declined in the 20th century. The British Commonwealth owned 63.6% of the mechanically propelled merchant shipping in the world in 1886, 45.2% in 1914, 37.4% in 1920, and 34.6% in 1927. By 1935 the proportion was 31.8%, and in 1939 it was 30.7%. The tonnage in 1939 was 21,001,925 tons gross, and despite heavy war losses amounting to nearly 12,000,000 tons gross, the 1939 tonnage total was exceeded by 1948. The Commonwealth's proportion of the world total, however, including the U.S. inactive fleet, had been reduced to 27%. By 1955 British tonnage had increased to 23,230,000 tons gross, but its percentage had dropped to 23.2%. In 1964, although total tonnage amounted to 27,544,738 tons gross, the largest commercially active fleet in the world, the percentage of total world tonnage had fallen further.

Most of the British-registered tonnage is owned and operated by the United Kingdom. In 1939, 6,722 ships of 17,891,134 tons gross were registered in the United Kingdom and 2,255 ships of 3,110,791 tons gross in the British Commonwealth outside the United Kingdom, mainly in Australia, Canada, Hong Kong, India, Malaya, New Zealand, South Africa, and the West Indies. Canada acquired a substantial fleet of vessels built during World War I, but after a few years most of the oceangoing ships were re-registered in the United Kingdom, although the beneficial ownership remained in Canada. The general movement toward flags of convenience, referred to above, however, started a tendency from 1956 onward for United Kingdom shipowners to register new tonnage in such commonwealth countries as Bermuda and the Bahamas, so that profits used for the purpose of replacing obsolescent tonnage would not be subject to United Kingdom taxation.

The privately owned United Kingdom merchant fleet at Jan. 1, 1964, excluding fishing vessels, tugs, and other nontrading vessels, as well as ships of less than 500 tons gross in size, exceeded 20,000,000 tons gross. Oil tankers and whaling factory ships accounted for nearly 8,000,000 tons gross of the total gross tonnage. Passenger and cargo liners totaled more than 8,000,000 tons gross and tramps about 3,000,000 tons gross. The remainder consisted of ships engaged in the coastal and short-sea trades. The United Kingdom continued to maintain the largest fleet of purely passenger ships in the world. They are engaged principally in the following trades: (1) Great Britain, France, and Ireland to Canada and the United States; (2) Great Britain to South Africa, Australia, New Zealand, India, and the Far East; (3) Great Britain to Spain, Portugal, and Central and South America; (4) cross voyages, for example Australia to the Far East and New York to Bermuda; (5) cross-channel services between Great Britain and Ireland and the continent of Europe; and (6) pleasure cruising in off-seasons from Great Britain, Australia, the United States, and elsewhere. Specially designed refrigerated cargo liners, often carrying up to 100 passengers, sail between Great Britain and Australia, New Zealand, South America, and South Africa, carrying homeward cargoes consisting mainly of meat and dairy produce. Cargo liners, many of them able to accommodate not more than 12 passengers, operate regular services from Great Britain and the continent of Europe to all parts of the world. They also sail between overseas countries, for example from the United States to India, from Canada to West and South Africa, from the United States to the Far East; and they may go around the world without touching Great Britain. British shipping services make a substantial contribution to the nation's balance of international payments through earnings of foreign currency. An inquiry carried out into the earnings of the British shipping industry for the year 1962 showed that receipts of foreign currency for freight, passenger fares, and charter hire totaled £853,000,000, while disbursements abroad totaled £490,000,000, making a net contribution of £363,000,000 to the nation's balance of payments.

Many of the well-known British shipping companies were founded in the earliest days of steam navigation, and some of them have even longer continuous histories. One of the largest shipping groups in the world is centred on the Peninsular and Oriental Steam Navigation Company, which operates passenger and cargo-liner services between Great Britain and the continent of Europe to India, Pakistan, Ceylon, Malaya, Australia, and the Far East. The group also includes the Orient Line passenger services to Australia, New Zealand, and the Pacific coast of North America and the refrigerated cargo-liner services to Australia and New Zealand operated by ships of the New Zealand Shipping Company and the Federal Steam Navigation Company. It includes the Nourse Line, trading between the West Indies and India; the British India Steam Navigation Company, trading between Britain and India and East Africa, as well as to Australia and in the Indian Ocean; the Hain Steamship Company, engaged in worldwide dry-cargo tramping; the General Steam Navigation Company, with a network of liner services ranging from the Mediterranean to the Baltic Sea; and the Union Steamship Company of New Zealand. In 1956 the Peninsular and Oriental (P. and O.) group broke new ground by ordering a fleet of 25 tankers.

The Cunard Line is famous for its transatlantic liners, but it also operates cargo services to the Mediterranean. The Port

Line, affiliated to the Cunard Line, sends refrigerated liners to Australia and New Zealand. The Brocklebank Line, another Cunard affiliate, runs to the Indian Ocean from Great Britain and the United States. The Union-Castle Line, which operates mail, passenger, and cargo services to South Africa, merged in 1956 with the Clan Line, a company running a worldwide network of cargo-liner services, to form the British Commonwealth Shipping Company. Royal Mail Lines operate passenger and refrigerated cargo-liner services to South America, and cargo-liner services to the Caribbean and the Pacific coast of North America, while their subsidiary, the Pacific Steam Navigation Company, operates passenger and cargo services to the west coast of South America. Another large organization is the Furness Withy group, operating passenger and cargo-liner services in many parts of the world. Most of the companies referred to above are public companies, but there are also some private companies or partnerships in which there is no public participation by means of shareholdings. Some of these, for example Alfred Holt and Company (the Blue Funnel Line) and Ellerman Lines, operate substantial fleets. The P. and O. group and several other shipping companies have substantial interests in independent air transport undertakings. Tramp shipping companies tend to be larger in number and smaller in size. Large tanker fleets are operated by the British Petroleum and Shell Oil companies, but there is also a large number of independently owned and operated tramp tanker companies.

2. Denmark.—The Danish merchant fleet, which totaled 705 vessels of 1,174,944 tons gross in 1939, suffered heavy losses during World War II, but by 1950 the strength of the fleet had more than recovered, and it reached 718 vessels of 1,269,011 tons gross. By 1964 the number of vessels had increased to 901 and the gross tonnage had advanced to 2,431,020 tons gross, of which 36% consisted of tankers. Most Danish ships are propelled by diesel engines, the Danish firm of Burmeister and Wain having built the motor ship "Selandia," the first oceangoing motor ship in the world. There is a substantial ferry traffic between Denmark and its neighbouring countries, but only about one-third of the foreign trade passing through Danish ports is carried in Danish ships. Danish shipowners, however, find much employment in overseas trading and in 1963 carried more than 9,800,000 tons of cargo between foreign ports, time charter not included. In 1963 gross earnings of Danish shipping in foreign currency totaled 1,211,000,000 Kr., excluding 736,000,000 Kr. in time-charter earnings. All except 231,000,000 Kr. was earned in purely foreign trade. By far the largest shipowning company in Denmark is the A. P. Møller concern, which operates around-the-world services as well as tramps and tankers, with a fleet totaling, in 1964, 963,000 tons gross. Next largest is the East Asiatic Company, running regular liner services to India, Australia, the Far East, and North America, with a fleet of nearly 326,000 tons gross. The United Steamship Company operates cargo liners to all parts of Europe, as well as to North and South America, while the J. Lauritzen concern operates refrigerated cargo-liner services to North and South America and to the Mediterranean, and also provides ships specially built for service in polar waters.

3. France.—The principal activity of the French mercantile marine is the carrying of trade from metropolitan France to other parts of the French Union, notably to those in North Africa, West Africa, and the West Indies, and to former French-controlled territories in southeast Asia. A worldwide network of liner services, however, is operated by the state-controlled Compagnie Générale Transatlantique (French Line) and other lines such as Messageries Maritimes. A considerable amount of coasting trade is carried in French vessels, and traffic between French territories in Africa and metropolitan France is largely reserved to vessels of French registry. The French liner fleet includes a substantial number of large passenger liners, like those of the French Line which operate in the North Atlantic trade, and a high proportion of specially designed banana carriers and fruit ships. The passenger liner fleet, however, experienced a marked reduction as former overseas possessions achieved political independence. France runs proportionately fewer dry-cargo tramp ships than do many other European nations.

In 1939 the French merchant fleet numbered 1,231 vessels totaling 2,933,033 tons gross. About half of this fleet was lost during World War II, but by 1949 its previous strength was restored, partly in consequence of a prompt rebuilding program and partly through the purchase of surplus U.S. ships and the acquisition of vessels as war reparations from defeated nations. Regular planned and subsidized shipbuilding programs enlarged the French-flag fleet until by 1964 it had reached the total of 5,116,232 tons gross, of which 43% consisted of tankers. Much of the postwar expansion was due to the building up of a tanker fleet much larger than that considered necessary before the war.

4. Germany.—German merchant shipping reached its peak in 1914 after a decade of highly successful competition on the high seas. In that year the German merchant fleet totaled nearly 5,500,000 tons gross, and the flags of such liner companies as Norddeutscher Lloyd, the Hamburg-America Line, and the Hamburg South America Line, were well known throughout the world. The defeat sustained in World War I, however, caused the disruption of this fleet. By 1920 less than 700,000 tons gross remained under the German flag. But by persistent effort, the merchant fleet was rebuilt, and although it had not quite reached 4,500,000 tons gross by 1939, its quality and efficiency were above average. A worldwide network of liner services had been reestablished, as well as a tramp fleet which flourished particularly in the Baltic and short-sea trades.

World War II resulted in a second eclipse of the German merchant fleet, and postwar restrictions on the size and speed of the ships that the Allies permitted to be built deferred the rebuilding of the fleet for several years. By 1949 the West German fleet had been reduced to 300,000 tons gross. A rapid expansion began in 1950, however, the bulk of the building program being confined to fast modern cargo liners of moderate size. By 1964 the fleet of the Federal Republic of Germany had grown to 2,504 vessels of 5,159,186 tons gross, nearly all of them constructed after 1950. The nucleus of a Federal Republic tanker fleet emerged, and plans were made for the resumption of the passenger trade.

5. Greece.—The Greek-flag merchant fleet expanded steadily between World Wars I and II, from 496,996 tons gross in 1920 to 1,790,666 tons gross in 1939, but this was due not so much to new construction as to the purchase of second-hand ships from other flags. As a result the average age of the ships of the Greek fleet was high, and in 1939 some three-quarters of the total tonnage was more than 20 years of age. For the most part this fleet was engaged in international dry-cargo tramping. Severe losses were suffered during World War II, but after the war large numbers of war-built Liberty ships were purchased from the United States and by 1950 the Greek-flag fleet totaled 1,348,874 tons gross. Thereafter a decline set in, for many Greek owners preferred to register their ships under foreign flags, especially under flags of convenience such as those of Panama and Liberia. Indeed, even before World War II, many Greek shipowners felt their gift for shipping commerce restricted by successive Greek legislatures, and transferred their operations to other flags. By the end of the 1950s, however, more favourable Greek maritime legislation brought about a large-scale repatriation of Greek-owned tonnage from flags of convenience to the Greek national flag. By 1964 the Greek flag fleet totaled 1,290 vessels of 6,887,624 tons gross. Owners of Greek nationality achieved a predominant position in world dry-cargo and tanker tramping in the years following World War II. They operated mainly from London and New York.

6. Italy.—Between World Wars I and II the principal Italian liner companies were liquidated and reconstituted as a state-owned organization known as the Finmare group, comprising four major lines, the Italia Line, the Lloyd Triestino Line, the Adriatica Line and the Tirrenia Line. Capital was provided by the state, which in 1937 also assumed control of the major shipbuilding yards, and in 1939 the Italian merchant fleet consisted of 1,227 vessels, totaling 3,424,804 tons gross. Only about 12% of this tonnage remained at the end of World War II, but by purchase, salvage and new construction the prewar total was passed by 1953. The state-owned liner group continued in existence and was responsible for the building of several large passenger liners, fast cargo liners, and specialized ships. The privately owned section of the

industry, engaged in liner, tramping, and tanker operations, also succeeded in rebuilding and expanding, and by 1964 the Italian-flag fleet had reached the record total of 5,707,817 tons gross, of which about one-third were tankers.

7. Japan.—The maritime expansion of Japan was extremely rapid between World Wars I and II, tonnage having almost doubled between 1920 and 1939, when the peak figure of 5,629,845 tons gross was reached. The geographical situation of Japan is favourable to the natural development of a large shipping industry, which was fostered between the wars by comparatively low wage rates and a measure of state support. A great deal of the tramp and liner trades between Japan, China, and other Pacific countries fell to Japan during this period, and in addition such large liner groups as Nippon Yusen Kaisha and Osaka Shosen Kaisha built up a worldwide network of passenger and cargo-liner services. Defeat in World War II left Japan with a largely obsolescent fleet totaling little more than 1,000,000 tons gross, but by 1950 postwar restrictions had been for the most part removed and the Japanese fleet again began to increase, largely as a result of government-sponsored shipbuilding programs. By 1964 the Japanese merchant fleet had reached a total of 10,813,228 tons gross.

8. Liberia.—The rise of a merchant fleet registered under the flag of Liberia is entirely a development of the decade following World War II. Whereas in 1939 the tonnage registered in Liberia was too negligible to be noted separately, by 1964 it totaled 14,549,645 tons gross, and the Liberian fleet was the third largest merchant fleet in the world. This phenomenal increase was due entirely to the postwar tendency of shipowners of other nationalities, especially Greeks and Americans, to register their new ships under flags of convenience, thereby evading onerous taxation burdens or other restrictive measures imposed by their national legislatures. Most of the ships registered in Liberia are vessels built after World War II, and in 1964, 8,619,449 tons consisted of tankers, almost all the remainder being dry-cargo ships engaged in international tramping.

9. The Netherlands.—There are three principal branches of the Netherlands shipping industry, which consists mainly of oceangoing passenger and cargo liners, tankers owned by the major oil companies, particularly the Royal Dutch Shell group, and coasting and short-sea vessels engaged mainly in trade with the United Kingdom and neighbouring and Baltic Sea countries. The granting of independence to Indonesia resulted in the Dutch liner companies losing much of their traditional network of services, but they established themselves in other trades, notably to the Great Lakes in North America, to Australia, and to the Far East. The Netherlands merchant fleet in 1939 totaled nearly 3,000,000 tons gross, a figure restored, despite war losses, by 1949. By 1964 the fleet had grown to 5,110,022 tons gross, the tanker fleet growing especially.

10. Norway.—The Norwegian merchant fleet expanded to a marked extent during the 20th century, owing to the traditional skill and seafaring bent of the Norwegians and to the dependence of Norway's economy on its income from international shipping services. Although the overseas trade of Norway itself is not sufficient to maintain a larger merchant fleet, the latter grew to comparatively large proportions mainly through the enterprise of Norwegian shipowners in the worldwide tramping trades. From mainly tramp origins, a number of liner groups developed, operating worldwide services, but the expansion of the fleet after World War II was largely due to the enterprise of tramp tanker owners. The Norwegian merchant fleet grew from 2,219,388 tons gross in 1920 to 4,883,813 tons in 1939, but about 40% of this tonnage was lost during World War II in the service of the Allied powers. Substantial purchases of U.S. war-built tonnage, together with an intensive postwar reconstruction program, helped to restore the prewar strength by 1949; but the potentialities of the international tanker market were such that Norwegian shipowners made even greater efforts to build. As a result, by 1964 the fleet had reached the figure of 14,477,112 tons gross, of which more than half consisted of tankers.

11. Panama.—Statistics of ships registered under the flag of Panama were not kept separately by Lloyd's Register of Shipping until 1924, when 15 vessels totaling 85,593 tons gross were listed. From 1931 onward there was a gradual increase in the merchant shipping registered in Panama, although the beneficial ownership was vested almost entirely in the United States, until the total of 717,525 tons was reached in 1939. After World War II the practice grew for U.S. oil companies and Greek and other independent tramp shipowners to register their ships under the flag of Panama, and by 1949 the merchant fleet registered in Panama exceeded 3,000,000 tons gross. By 1954 the figure of 4,000,000 tons gross had been exceeded, and this increased to 4,269,462 tons by 1964, when 2,253,418 tons gross consisted of tankers.

12. Sweden.—The Swedish merchant fleet reached 1,000,000 tons gross in 1913 and gradually increased its tonnage until by 1939 it reached 1,577,120 tons gross. This expansion continued after World War II and by 1949 the total exceeded 2,000,000 tons gross. In 1964 the total reached 4,308,042 tons gross, of which about 34% consisted of tankers. In addition to a substantial coasting and short-sea traffic, and a fair-sized oceangoing tramp fleet, Sweden has a number of well-established liner groups, such as the Brostrom concern, which includes the passenger liners of the Swedish American Line, the Transrederierna group, operating worldwide cargo-liner services, and the Johnson Line, which specializes in high-speed cargo-liner services. Iron ore is one of Sweden's major exports, and the Grangesberg-Oxelosund concern built up a large fleet of ore carriers to cope with this trade, many of the larger units being able to carry iron ore exports on the outward voyage and cargoes of imported oil products on the return voyage.

13. United States.—In 1913 the United States oceangoing merchant fleet, including the coastwise fleet, totaled nearly 3,000,000 tons gross. As a result of an emergency shipbuilding program toward the end of World War I, the U.S. oceangoing fleet reached a total of 14,738,506 tons gross by 1922, but a gradual decline then set in until by 1939 the total oceangoing fleet amounted to 8,909,892 tons gross, of which only about two-thirds was active. High wage and shipbuilding costs made it impossible for the U.S. privately owned merchant fleet to compete effectively with foreign flags. In an endeavour to stem the decline of the U.S. foreign-going fleet, the Merchant Marine Act of 1936 introduced a system of differential subsidies for the building and operating of liner services on specified "essential trade routes." These helped to sustain the cargo-liner companies, although they failed to provide any incentive for private investment in shipping. They did not apply to the tramp companies, which almost disappeared, or to the tanker companies, which found the obligations of the shipbuilding subsidy provisions irksome and sought refuge in registration in Panama and other countries abroad, or to the intercoastal and coastwise shipping companies which, despite the protection afforded them by the reservation of their trades to U.S. flag ships, were unable to cope with the competition of inland transport systems.

World War II saw another intensive shipbuilding effort in the United States, which agreed with Great Britain to build chiefly cargo ships of emergency type, while Britain for the most part built warships. As a result the United States merchant fleet in 1946 totaled 36,000,000 tons gross. This was more than half the world total tonnage at the end of World War II, because ships of other flags were often lost, and few losses were replaced during the war years. Disposal of the U.S. surplus tonnage to the other Allied powers began in 1946 and many ships were sold at favourable prices. By 1950 the United States-flag merchant fleet had been reduced to 25,000,000 tons gross, but of these 14,000,000 tons gross had been permanently laid up in the emergency defense reserve fleet. The Merchant Marine Act of 1936 continued in force and various other legislative measures were taken in an attempt to maintain the volume of U.S.-flag shipping in commercial service. At least half the ships carrying government-sponsored cargoes had to be of the U.S. flag. United States-controlled tanker tonnage under foreign flags continued to increase, and the subsidized passenger and cargo liners maintained their tonnage, but the decline of coastwise and intercoastal shipping continued.

By 1964 the total United States seagoing merchant fleet, including inactive ships but excluding Great Lakes vessels, comprised

3,222 ships totaling 20,351,334 tons gross. Of the oceangoing fleet 390 vessels, totaling 4,428,272 tons gross, were tankers.

United States shipping on the Great Lakes continued busy. Tonnage reached a peak of 2,611,040 tons in 1934. By 1956 the total was still just over 2,500,000 tons gross, but prospects began to decline with the decrease of iron ore deposits in the area. The completion of the St. Lawrence Seaway in 1959 opened up the Great Lakes to intense competition from foreign-flag vessels engaged in oceangoing trade, and by 1964 the U.S. registration on the Great Lakes had fallen to 2,078,915 gross tons.

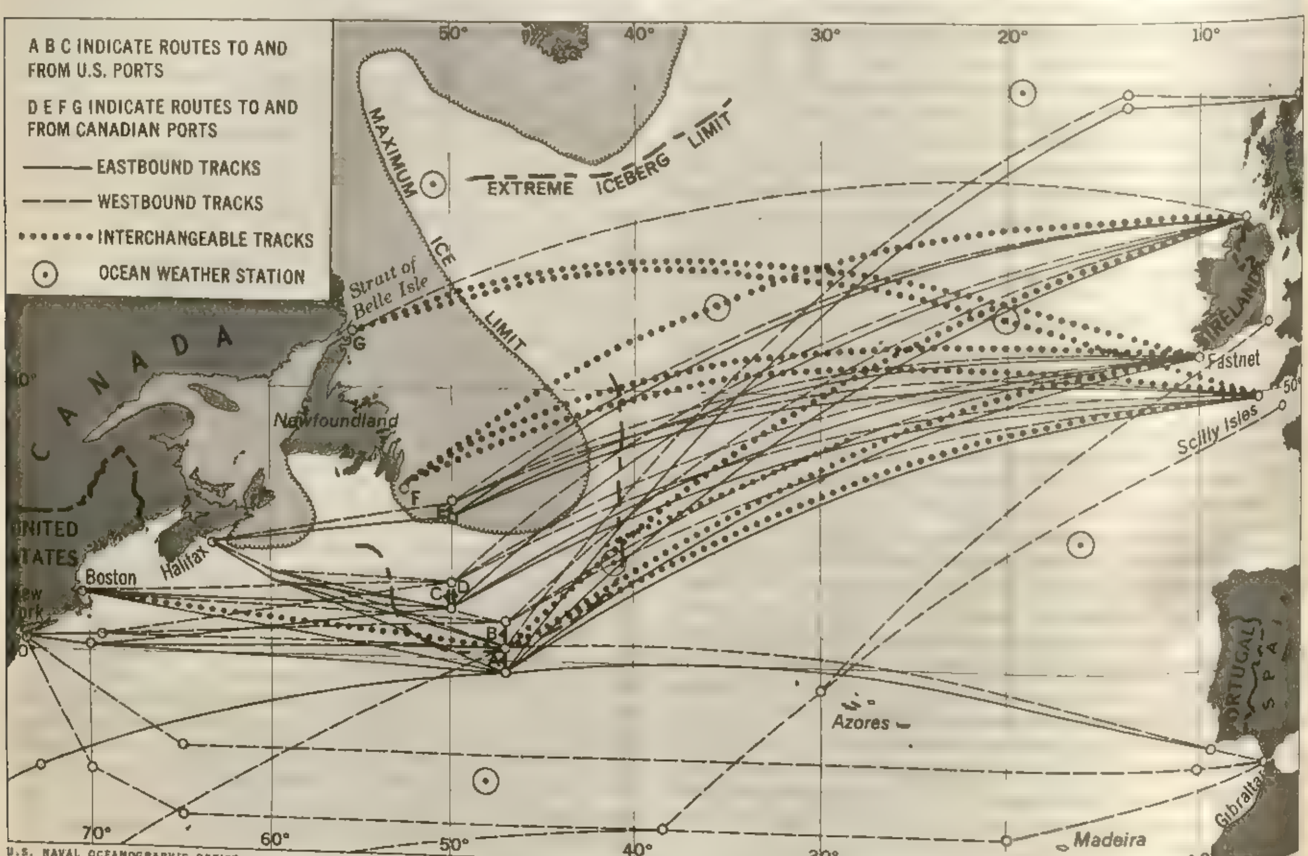
SHIPPING ROUTES. When man first began to venture on the sea, his route was determined by the landmarks along the shore. As the science of navigation developed and he could determine his latitude by the heavenly bodies, he was no longer bound to the coast. It was not, however, until the perfection of the chronometer by John Harrison in 1762 that a shipmaster could accurately plot both his latitude and longitude. Then with exact positions he became more aware of the effects of winds and currents on his ship and began shaping his course to take advantage of them. The shortest route was not always the quickest one: for example, the westbound clipper ships from Europe to America made much faster passages by following a southerly route to avoid the influence of the Gulf stream and the prevailing westerly winds.

No systematic effort was made to study regular ship routes until the decade preceding the American Civil War when Lieut. Mathew Fontaine Maury, then superintendent of the depot of charts and instruments, the forerunner of the present naval oceanographic office, enlisted the aid of shipmasters generally to furnish him with copies of their log books. From these he produced his *Pilot Charts* with recommended routes that by estimate saved the merchants and shipmasters of the United States more than $2,000,000 annually, and those of Great Britain about $10,000,000 each year. His contributions to the maritime world earned him the title of "Pathfinder of the Seas."

The development of steam navigation ended the shipmaster's dependence on wind as the sole means of propulsion and led to the gradual adoption of the ship lanes of today. The shortest distance between two ports is a great circle on the earth's surface and the modern high-powered steamer follows such routes whenever practicable. However, deviations are made to avoid intervening land masses, ice-infested waters and regions of continuous adverse meteorological conditions. Low-powered steamers travel routes taking advantage of favourable winds and currents. The leading hydrographic offices of the world have made studies of the various routes and publish in their volumes of sailing directions advice on the routes to follow. While the high speed of planes has led to international agreements on air lanes and a rigid control on plane flights, there are at present no mandatory international rules governing the ocean lanes, and the selection of the routes to be followed is left to the discretion of the steamship owners and shipmasters.

North Atlantic.—The combination of frequent fog, high density of travel and the annual incursion of ice has led to the establishment of definite ship lanes that are recognized internationally in the North Atlantic between the United States and Europe; these are traveled by the largest and fastest liners. The danger of collision in the North Atlantic was first recognized by Maury, following the sinking of the U.S. mail steamer "Arctic" in Oct. 1854 by the French steamer "Vesta" in a thick fog about 50 mi. (80 km.) east of Cape Race, Nfd., which resulted in the loss of about 300 lives. This disaster inspired him to include in his *Sailing Directions* (1855) a section "Steamer Lanes Across the Atlantic," wherein were graphically depicted and recommended for the first



NORTH ATLANTIC SHIPPING ROUTES

time separate lanes for steamers eastbound and westbound that would not only lessen the danger of collision between ships but would also provide nearby help in case of disaster. The lane to Europe crossed the 50th meridian of west longitude in latitude 42° and was from 15 to 20 mi. (24 to 32 km.) wide; the lane from Europe crossed the 50th meridian of west longitude 200 mi. (322 km.) to the northward and was from 20 to 25 mi. (32 to 40 km.) wide, the latter being made wider on account of the greater percentage of fog, the greatest width in both lanes being given where most fog was to be expected.

The pioneer work of Maury was continued by the U.S. navy hydrographic office which emphasized the necessity of lanes across the Atlantic, not only to obviate collisions, but also to avoid the danger from ice. In 1875 the Cunard Steamship company ordered its shipmasters to follow ship lanes that were laid south of the zone into which icebergs normally drifted. Several of the other large and more progressive passenger lines followed this policy, and as a result the number of accidents due to ice showed an encouraging decline. In the meantime, through the medium of the monthly *Pilot Chart of the North Atlantic Ocean*, the hydrographic office pointed out to the maritime world in general the need to adopt steamer lanes.

The International Marine conference, held at Washington, D.C., in 1889, and attended by delegates from 26 maritime countries, decided: "Steamer lanes for trans-Atlantic navigation are not adopted, although the various steamship companies are urged to adopt regular routes for vessels of their own line." At the urging of the hydrographic office, a conference was held in 1891 between representatives of five principal trans-Atlantic steamship companies, the Cunard, White Star, Inman, National and Guion lines, to consider the lanes as recommended on the *Pilot Chart*. These routes were formally adopted to be followed by all ships of the lines concerned and in 1898 the North Atlantic Track agreement came into being with the adherence of all the major passenger lines of that day. The agreement, although purely voluntary in nature, has remained in effect into the second half of the 20th century with seasonal shifts of the lanes being made as recommended by the commandant of the U.S. coast guard and the U.S. hydrographer. This adoption of recognized steamer lanes contributed greatly to the safety of navigation in the North Atlantic and was especially gratifying to the hydrographic office, which had so long advocated the lanes as shown on the *Pilot Charts*.

As a result of the sinking of the British steamer "Titanic" on April 15, 1912, with a loss of over 1,500 lives, the first International Convention for Safety of Life at Sea was convened at London in 1913. The steamer lanes were considered and the following resolution adopted: "The selection of the routes across the North Atlantic in both directions is left to the responsibility of the steamship companies, nevertheless the High Contracting Parties undertake to impose on these companies the obligation to give public notice of the regular routes which they propose their vessels should follow, and of any changes which they make in them. The High Contracting Parties undertake, further, to use their influence to induce owners of all vessels crossing the Atlantic to follow, as far as possible, the routes adopted by the principal companies." Similar resolutions were adopted at the subsequent conventions of 1929, 1948 and 1960.

With but minor changes, the lanes of the North Atlantic Track agreement, used by the principal steamship companies prior to the London conference, remained unchanged until 1924 when the tracks A, B, C, D, E, F and G were adopted. These, with slight modifications, are the tracks in use today and are shown on the accompanying chart. The routes are seasonal and provide, as far as possible, for safety from the danger of ice, fog and collision with fishing vessels on the Grand Banks. Tracks A, B and C are the United States-European lanes, while D, E, F and G relate to vessels bound to and from Canada. The seasonal United States track employed is the one that is ice-free.

An additional safeguard to the North Atlantic lanes resulting from the conference of 1913 was the establishment of the International ice patrol, which, during the ice season, guards the region in the vicinity of the Grand Banks of Newfoundland, warns ships of dangerous ice, recommends safe tracks and makes studies of ice conditions. The cost of the patrol is borne by those nations whose vessels traverse the area. The management of the ice patrol is entrusted to the United States government and is carried out by the U.S. coast guard.

Originally conducted with surface craft, the ice patrol today is maintained principally by reconnaissance aircraft based at the headquarters of the commander of the international ice patrol in Argentia, Nfd. Only in serious ice years is it necessary to dispatch a cutter to stand by ice known to be drifting into the steamer lanes. Since the inauguration of the International ice patrol services, not a single life has been lost or a vessel sunk on the United States-European lanes as the result of collision with icebergs. *See* also COMMERCE, HISTORY OF. (W. G. WT.)

SHIP'S BELLS, in use as early as the 15th century, make possible the distinctive method of sounding the time on board ship. The mariner's 24-hour day is divided into six watches, each four hours long, except that the 1600 to 2000 watch (4 P.M. to 8 P.M.) may be "dogged" or shortened into the first and second dogwatches, each two hours long, in order to rotate the watches and to allow the men on duty to have their evening meal. Through the 18th century, time was ordinarily measured on board ship by using a sandglass which approximated 30 min. The quartermaster or ship's boy turned the glass when the sand ran through, and it became customary for him to strike the bell as he did this. Eight times in each watch the glass was turned and the number of strokes on the bell indicated the number of half hours elapsed after the men came on deck. These strokes are sounded in pairs, with an interval following each pair.

The time and place of origin of this seagoing custom is unknown but it was nearly universal among Europeans and sailors of the Mediterranean area by the 18th century. After the mutiny at the Nore (1797), British ships followed a special numbering in the dogwatch. From 1600 to 1800 the usual bells are struck, but at 1830 (6:30 P.M.) only one bell is struck instead of five; two at 1900 (7 P.M.); three at 1930 (7:30 P.M.); and eight bells at 2000 (8 P.M.). Thus, the signal for the mutiny, five bells in the second dogwatch, has never been given.

International law required that a ship at anchor sound a series of rapid successive strokes on the bell as a fog signal, while at other times this is a fire signal. (J. B. HN.)

SHIPS' FIGUREHEADS: *see* FIGUREHEADS, SHIPS'.

SHIRAKAWA (1053–1129), Japanese emperor who succeeded his father Gosanjō II on the throne in 1072. The times were troubled. The encroachment of private estates (*shōen*) on the public domain seriously undermined the economic foundations of the imperial government. The warrior monks of the nearby temples threatened the capital city of Kyōto, and the weakening of the Fujiwara family, which had dominated the emperors for over two centuries, made for bitter factionalism within the court. Shirakawa left the throne in 1086 and as retired emperor (*jōkō*) succeeded in retaining power in opposition to the Fujiwara regent (*kampaku*). Drawing around him a group of courtiers, many of whom were from the Minamoto and other non-Fujiwara families, he established an administrative centre replete with judicial functions and a military guard. This was the cloister government (*in-no-chō*) through which former emperors exercised power until 1183. Shirakawa himself held the reins of government until 1129. Although at first Shirakawa sought to reduce private estates, he soon gave up the effort and became instrumental in converting large tracts of public domain into imperial *shōen*. With these sources of wealth he lavishly patronized Buddhism. He failed to strengthen the imperial government and prevent the rise of the provincial warrior gentry. *See* also JAPAN: *History*. (J. W. H.)

SHIRAZ, a city of Iran and capital of Fars (ancient Persis) *ostan* (province), lies at an altitude of 5,200 ft. (1,585 m.), 115 mi. (185 km.) ENE of Bushire, its port on the Persian Gulf. Pop. (1964) 215,000 city; 325,919 environs. Famous for its poets and its wine, it is both a historic site and an attractive modern town (the first on the plateau to have piped water), with wide, tree-lined boulevards, gardens, shrines, mosques, and other monuments. It is the birthplace of the two Persian poets, Sa'di and

Hafiz (*qq.v.*), whose garden tombs, both resplendently renovated, lie on the outskirts.

Inscribed clay tablets discovered in 1935 reveal that to build his palace at Persepolis Xerxes I, in 466 B.C., employed workers from Shiraz, which retained its importance during the Seleucid, Parthian, and Sassanid periods, swelling into a town when it absorbed the population of the holy city of Istakhr on its final destruction by the Arabs in the mid-11th century. The Mongols in the 13th century spared the city and built the New Mosque (1218), the Abesh Khatun (tomb of the last Atabeg ruler), and the fortress Bagh-e-Takht. In 1387 and again in 1393 Timur (Tamerlane) occupied Shiraz which, with its Masjid-e-Jume or Congregational Mosque (894), Shah Cheragh shrine (1344–49), and great library, had become a Muslim centre rivaling Baghdad. In prosperous Safavid times (1501–1736) the striking tiled Madrasseh (theological school; 1615) and the avenue on the road to Isfahan were constructed, but in 1724 the Afghan invaders, and in 1744 their vanquisher Nadir Shah himself, both sacked the city. From the calamitous floods (1630, 1668), pestilences, famines, and earthquakes (chiefly 1824, 1853) it is remarkable how much of Shiraz has survived. The remains of the old capital and the buildings constructed by the *vakil*, or regent, Karim Khan Zand (1750–79), who made Shiraz his capital, lie within the old city, whose western walls are marked by the Sa'di and Darius avenues. These buildings include the regent's mausoleum, an octagonal tiled kiosk, now the museum; the Arg, or citadel, now the prison; the Vakil Bazaar; and the Vakil Mosque. The two principal avenues, Zand and Lotf-e-Ali Zand, run east–west from the old city to the new. Buildings in the new city include the Persian Church of St. Simon the Zealot, the army headquarters, the *ostandari* (governor-general's office and residence), several hospitals including the Nemazee, Khalili, and Christian hospitals, and Pahlavi University (1948) with its faculties of arts and science, agriculture, medicine, and engineering.

Shiraz is still the trading centre for the Kashgai (Qashgai) and Khamseh tribes, and carpets and rugs of excellent quality are made in the surrounding area. There are cement, sugar, and fertilizer factories and several textile mills, but the crafts of gold, silver, and khatam inlay work still flourish. The local lambskins, well known for their quality, are exported. Main roads connect the city with Bushire, Isfahan (via the ancient sites of Persepolis and Pasargadae), and Teheran, and with the southwestern towns of Abadan, Khorramshahr, and Ahvaz. Daily bus and air services operate to Isfahan and Teheran.

SHIRE, a river of Africa which flows for about 300 mi. (480 km.) through southern Malawi (Nyasaland) to join the Zambezi River in Mozambique (Portuguese East Africa). Together with a left-bank tributary, the Ruo, part of its lower course forms the southwestern boundary of Malawi with Mozambique. The Shire is mainly the overflow channel from Lake Nyasa to the Zambezi, although it has also a comparatively small local drainage from the southern part of the Nyasa Valley. The river issues from the southeastern end of Lake Nyasa at Monkey Bay and flows slowly past Fort Johnston before entering the shallow Lake Malombe, from which it flows, still slowly, for 22 mi. (35 km.) to Liwonde. At Matope it begins its 50-mi. (80-km.) stretch known as the Murchison Cataracts or rapids. These end about 12 mi. (19 km.) above Chikwawa, 12 mi. below which the river spreads out into the vast Elephant Marsh, about 10 mi. (16 km.) wide, which continues, alternately narrowing and widening, to near the Portuguese town of Vila Bocage; below Port Herald it is known as Ndindi Marsh. The excessive flooding of this part of the river valley is caused largely by the gradient of the lower Shire being lower than that of the Zambezi, whose waters flood back along the Shire channel and also reach the Ndindi marshes by the Ziu Ziu overflow from the Zambezi.

The course of the Shire divides naturally into three tracts. The first, from Monkey Bay to Matope is 82 mi. (132 km.) long with a fall of 23 ft. (7 m.), the gradient over considerable stretches being as low as 1:100,000. It is thought that this tract may be a part of the former southward extension of the lake. There are no rock outcrops in the riverbed. The second tract extends from Matope for 50 mi. (80 km.) over rugged gneiss outcrops. Five main rapids occur: at Matope Bridge, Nkula Falls, Tedzani Falls, Mpatamanga Gorge, and Hamilton Falls (12 mi. upstream from Chikwawa). Together these constitute the Murchison Cataracts in which the river descends 1,260 ft. (384 m.). The third tract is the Elephant and Ndindi marsh area, where the gradient is about two feet to the mile and the floodbasin is covered with reeds, elephant grass, and papyrus. The discharge of the river is determined very largely by the level of the water in Lake Nyasa. From 1915 (lowest recorded level) to 1937 (highest recorded level) there was no outflow from the lake. In 1937 the waters broke through the obstructions in the riverbed and forced their way again to the Zambezi.

Plans for development include the control of the water level of Lake Nyasa; the construction of a barrage and low-head power station at Matope; the clearing and draining of the marshes; and pilot experiments on various forms of irrigation.

See J. G. Pike and G. T. Rimmington, *Malawi: a Geographical Study* (1965); N. J. Cochrane, "Lake Nyasa and the Shire River," *Proc. Instn Civ. Engrs,* vol. 8 (1957). (J. H. WN.)

SHIRE COURT, in England, a medieval court for the conduct of administrative, financial, and judicial business, based on the shires or counties, which were the most important administrative units in Anglo-Saxon local government. The shire, with its court, appears to have been fully established by the reign of Edgar (959–975). The shire court met in Saxon days in its traditional meeting place in the open air twice a year for specially full meetings attended by the great landowners of the shire. The king sent his instructions to these meetings by his ministers and all the business of government, both judicial and financial, was dealt with. Between those two meetings routine business was conducted in smaller meetings, probably held every four or five weeks. The sheriff presided and called on the suitors (in theory all the great landowners and representatives of the tenants, but eventually few besides the holders of particular plots of land to which the burden of suit of court had become attached) to declare the law. The Norman and Angevin kings threw more work on the court by the issue of many "viscontiel" writs, ordering the sheriff to do justice in particular cases. But the increasing complexity of the law, royal distrust of powerful sheriffs, the rapid development of the central courts of justice, and the increasing frequency of judicial eyres all combined to lessen the judicial importance of the old shire courts. Nevertheless, although no actions of trespass, debt, or detinue could be brought which involved a greater sum than 40*s.*, a considerable amount of litigation was done in the shire courts as late as the mid-13th century. Apart from proceedings in outlawry the shire court was not a court of record.

SHIRLEY, JAMES (1596–1666), English poet and dramatist, a leading playwright in the decade before the closing of the theatres by Parliament in 1642, is best remembered for the poem beginning

> The glories of our blood and state
> Are shadows, not substantial things;
> There is no armour against Fate;
> Death lays his icy hand on Kings . . .

Born in London and baptized on Sept. 7, 1596, he was educated at Merchant Taylors' School (1608–12), and, after service in a moneylender's household, matriculated at Catharine Hall, Cambridge, in 1615. Graduating in 1617, he took orders, and went to St. Albans, where he married (1618) and (*c.* 1621) became Master of the Grammar School. In *c.* 1624, having become a Catholic, he moved to London and turned playwright. His first play, *Love Tricks, or the School of Compliments*, was performed in 1625 at the Phoenix, Drury Lane, for which theatre most of his plays until 1636—about two a year—were written. When the theatres

closed in May 1636 as a plague precaution, he went to Dublin, where he was dramatist for St. Werburgh's Theatre. He returned to London in 1640, to succeed Massinger as dramatist for the King's Men at the Blackfriars. The theatres having closed, in the Civil War he may have served with the king's forces, and then returned to teaching, at Whitefriars, London, publishing two Latin grammars, some nondramatic verse, and four masques. Anthony à Wood (*q.v.*) reports that Shirley and his wife died the day after they were forced by the Great Fire to leave their house in Fleet Street; they were buried on Oct. 29, 1666, at St. Giles-in-the-Fields.

Thirty-one plays, five masques, and a five-act moral allegory are extant. The most elaborate of the masques was the Inns of Court *The Triumph of Peace* (1634), with scenery by Inigo Jones and music by William Lawes. *The Contention of Ajax and Ulysses for the Armour of Achilles* (printed 1658, but performed earlier) ends with the dirge quoted above. He wrote plays in most of the current modes, but never became completely subordinate to Caroline courtly fads. Among the best are the mildly satirical comedies of fashionable London life: *The Witty Fair One*, a model of inventive plotting and fresh use of traditional material, *Hyde Park*, *The Ball*, and *The Lady of Pleasure*, his most polished comedy of manners; all performed between 1626 and 1635. *The Young Admiral* (1633) and *St. Patrick for Ireland* (?1639) are notable, the first for its ingenious and genteel tragicomic heroics, and the second for its astonishing mixture of farce, romance, miracle, and show. His best tragedies, both on dark, Italianate themes, are *The Traitor* (1631) and *The Cardinal* (1641), a play of love, politics, revenge, and poison. This, like a number of Shirley's other plays, was revived at the Restoration and was twice enjoyed by Pepys.

SHIRLEY, WILLIAM (1694–1771), colonial governor of Massachusetts, was born at Preston in Sussex, Eng., Dec. 2, 1694. He studied at Cambridge and was later admitted to the bar. In 1731 after 11 years of law practice in England, he migrated to Boston, Mass. Shirley was a constant but not always successful office seeker. His loyalty to the imperial prerogatives, his ability, and his friendship with the duke of Newcastle resulted in his being appointed admiralty judge in 1733 and the king's advocate general in 1734. In 1741 he was appointed to the governorship of Massachusetts and proved to be a popular and successful governor in a rather difficult period. He gave Massachusetts a relatively sound currency.

Shirley's most important achievements as governor were in the realm of colonial and imperial defense. He was quite successful in building up the Massachusetts fortifications and unusually astute in his analysis of the nature and importance of the struggle between England and France for control of North America. During King George's War (1740–48) he organized and planned Britain's one great victory, the capture in 1745 of Louisburg on Cape Breton Island. In 1753 Shirley renewed his recommendations for united action against the French and drew up a plan for offensive warfare. After the defeat and death of Gen. Edward Braddock in western Pennsylvania in 1755, Shirley became commander in chief of the English forces in America but neither in America nor in England could he command the respect and cooperation necessary to carry out his well-conceived plans. After the failure of his expedition against Ft. Niagara he was replaced as commander and governor and was recalled to England where he was charged with treason. After being vindicated he was appointed governor of the Bahamas in 1761. In 1770 he returned to Roxbury, Mass., and died there on March 24, 1771.

See G. A. Wood, *William Shirley, Governor of Massachusetts, 1741–1756* (1920); C. H. Lincoln, *Correspondence of Wm. Shirley* (1912). (Ra. Mu.)

SHISHKOV, ALEKSANDR SEMENOVICH (1754–1841), Russian writer and statesman noted for his Slavophil, nationalistic religious fervour. A naval officer by training, he rose to the rank of vice-admiral and was appointed a member of the Admiralty College under the emperor Paul I. Disagreeing, however, with the reforms instituted on Alexander I's accession, he retired from official life and devoted himself to literature. He became engrossed in the study of Old (Church) Slavonic and regarded himself as a philologist, but his linguistic studies became a vehicle for nationalistic propaganda. He attacked everything new, whether administrative or literary. A member of the Russian Academy from 1796, he sought to preserve the purity of the Russian language, praised 18th-century Russian writings, and criticized the literary innovations of Nikolai Karamzin and French influence on Russian vocabulary, thought, and manners. He asserted that Old Slavonic was the root of modern Russian, and demanded that words of foreign origin be replaced with words derived from Old Slavonic. To encourage and train young *literati* in pure Russian literature, Shishkov organized literary meetings that were designed to instill in Russian society greater patriotism through Russian language and literature. The works read at these meetings were published, among them Shishkov's own *Discourse on Love for One's Country* (1811).

As the life-and-death struggle with France approached (*see* Napoleonic Wars), Shishkov's ultrapatriotism was useful, and Alexander I, impressed by the *Discourse*, recalled Shishkov to public service as secretary of state. Accompanying the emperor to Vilna, he wrote all the major orders and rescripts in his usual patriotic style. Nominated president of the Russian Academy in 1813 and a member of the State Council in 1814, Shishkov in 1824 became minister of education and director of non-Orthodox religious affairs. He opposed mass education, instituted strict censorship, and persecuted the biblical societies for spreading revolutionary books. Shishkov retired from the ministry of education in 1828 but remained head of the Academy. On his death in 1841 the Russian Academy was closed and its functions were assumed by the newly created Division of Russian Language and Literature of the Academy of Sciences. The ideas of Shishkov and his associates found amplification in the highly romantic nationalism of the Slavophils (*q.v.*) of the 1840s. (G. A. Ln.)

SHIVAISM (Shaivism), the cult of the god Shiva (Śiva), which, with Vishnuism and Shaktism (*qq.v.*), is one of the main forms taken by modern Hinduism (*q.v.*). Shiva originated in the Vedic god Rudra (*see* Vedic Religion), who became identified with him. Although Rudra is celebrated in only a few hymns of the Rigveda, it is clear that from the beginning he was one of the chief gods. A beautiful litany, the *Satarudriya*, addressed to Rudra, forms part of the Yajurveda. In the Atharvaveda and the Brahmanas there are allusions to Rudra as well as descriptions of rituals connected with his worship. The fact that the word *rudra* sometimes occurs in the Rigveda as an epithet meaning "terrible" has led some scholars to deduce that Rudra was a completely malevolent God who was referred to as *shiva* ("auspicious") only euphemistically, but this view cannot be reconciled with the passages in which prominence is given to Rudra's benevolent aspect. According to one derivation of the word *rudra*, Rudra is so called because he drives away sin and suffering. The name has also been interpreted to mean "he who attenuates sin." Some of the other names by which Rudra-Shiva is known are Sambhu ("benignant"), Samkara ("beneficent"), Pasupati ("lord of cattle"; *i.e.*, souls), and Mahadeva ("great god").

In the Epic period (*c.* 600 B.C.–*c.* A.D. 200) the function of cosmic destruction is assigned to Shiva, but since destruction of the world only precedes re-creation, this is considered to be an act of grace in Hinduism. The consort of Shiva is Ambika, the Mother, known by various names—Parvati, Uma, Durga, and Kali. This divine couple has two sons, Ganesha and Karttikeya (*q.v.*).

In modern India Shiva is the supreme God to the devotees of

ROYAL ACADEMY OF ARTS, LONDON

DANCING SHIVA (NATARAJA) SOUTH INDIAN BRONZE, 12TH–13TH CENTURY A.D. IN THE MUSEUM OF ASIATIC ART, AMSTERDAM

Shaivism, who are found all over India. There are several schools of Shaiva thought, ranging from pluralistic realism to absolute monism, but they all agree in recognizing three principles: *pati* or God, *pasu* or individual soul, and *pasa* or bonds that confine the soul to earthly existence. The goal set for the soul is to get rid of its bonds and gain *shivatva* (the nature of Shiva). The paths leading to this goal are *carya* (external acts of worship), *kriya* (acts of intimate service to God), *yoga* (meditation), and *jnana* (knowledge). Among the classical schools of Shaivism are the Trika (or Pratyabhijna) of Kashmir, Virashaivism of the Kanarese and Telugu areas, Shaiva-Siddhanta of the Tamils, and Shivadvaita of Shrikantha and his followers. Shaivism, like some of the other forms of Hinduism, spread in the past to other parts of southeast Asia, including Java and Bali, Champa and Cambodia.

In popular Hinduism the god retains his character as the destroyer of the world, the third member of the Hindu trinity (with Brahma, the creator, and Vishnu, the preserver), and he is a somewhat remote though by no means always terrifying figure. Shaiva temples always contain an image of Nandi, the sacred bull, the mount of Shiva, symbolic of the soul. He is represented anthropomorphically in a variety of ways, often as a dancer (Nataraja), a form which has inspired many beautiful works of art. His most familiar symbol is the linga (lingam), representing that which has a shape and yet no definite shape, an object of great sanctity to which offerings of water, flowers, fruit, and rice are made.

See S. Dasgupta, *History of Indian Philosophy*, vol. 5 (1955); T. M. P. Mahadevan, *The History and Culture of the Indian People* (1954).
(T. M. P. M.)

SHIVPURI, a town in the Gwalior division of Madhya Pradesh, India, and the administrative headquarters of the district of the same name, lies 75 mi. (121 km.) SW of Gwalior at the terminus of the Gwalior-Shivpuri Light Railway. Pop. (1961) 28,681. It is situated on an elevated watershed from where streams radiate in all directions. Formerly called Sipri, the town was the headquarters of the Narwar District of Gwalior state. In the 17th century it was granted to Amar Singh Kachwaha of Narwar. In 1804 it was seized by the Sindhias, whose palace is one of the town's notable features. Shivpuri increased in importance as a trade mart following the opening of the railway and is a centre for the distribution of forest produce.

Shivpuri District, originally known as Narwar Zila, has an area of 3,986 sq.mi. (10,324 sq.km.) and a population (1961) of 557,954. The greater part is cut up by jungle-covered ridges striking from northeast to southwest, but the area lying west of the Vindhyan spurs is fairly level and fertile, and jowar, wheat, and oilseeds are grown there. The district also possesses a national wildlife sanctuary. Narwar, the former district headquarters, is of considerable historical and archaeological interest. It has an old fort picturesquely situated on the steep scarp of the Vindhyas.
(S. M. A.)

SHIZUOKA, prefecture (*Ken*) on the Pacific coast in central Japan. Area 3,000 sq.mi.; pop. (1960) 2,756,271. Favoured by a warm climate, Shizuoka has developed a varied agriculture. Oranges and tea are the chief products, and fishing is highly developed at Shimizu, the principal port. The processing of food and other industries are important. Hamamatsu (*q.v.*) is famous for the manufacture of musical instruments. Topographically and geographically the eastern and western sections differ. Volcanoes and hot springs dominate the east, while large river valleys occur in the west. Shizuoka is served by the Tōkaidō central trunk railway line.

Shizuoka, the prefectural capital (pop. [1960] 328,819) is situated on the delta of the Abegawa River. The climate is mild. Shunpei, as Shizuoka was called until 1869, was a castle town as well as one of the 53 stage towns on the Tōkaidō highway. About 70% of Japan's tea is raised in its environs and the city is famous as a trading and processing centre for green tea. Shizuoka is the site of Shizuoka University, a women's pharmaceutical college, and several industrial and agricultural experimental stations.
(R. B. H.)

SHKODËR (ancient Scodra; Italian Scutari), a town of northwestern Albania and administrative centre of Shkodër *rreth* (district), 75 mi. (120 km.) NNW of Tiranë by road. It lies at the southeast end of Lake Shkodër (Skadarsko Jezero), where the Buenë (Bojana) River leaves the lake for the Adriatic Sea, and at the edge of a wide plain surrounded southeast, east, and north by high mountains; it is overlooked by Mt. Tarabosh to the west across the Buenë. Pop. (1960) 43,305, more than half Roman Catholics, with many Muslims and a few Orthodox.

Shkodër is the most historic town in Albania. It is dominated by the old citadel on an isolated rock at the south, past which the Kiri flows into the Buenë. The Drinasë, the new channel cut by the Drin in 1858, joins the Kiri just above the Buenë and periodically causes flooding in the old town near the citadel by raising the water level in the lake. The newer part of the town spreads to the north. The substantial remains of the fortified citadel are mainly Venetian (14th century), built on the site of an earlier walled town erected (or restored on an Illyrian site) by the Romans and repaired by Byzantines and Slavs; the Venetian walls were later strengthened by the Turks. The old part with its market and narrow streets is a typical old Balkan town. There is a Roman Catholic cathedral (19th century) and modern administrative and other buildings. Shkodër has been the seat of an archbishop (though not continuously) since the 4th century. The national poet Gjergj Fishta (Franciscan, 1871–1940) lived, taught, and wrote at Shkodër, and his community especially contributed much to the country's literature and national spirit.

The town is the traditional market centre for the whole northern mountain area, which is mainly Catholic but includes the Muslim clans of the northeast. Before World War II it was the most colourful town in Albania. Surfaced roads now link Shkodër with the main northern centres as well as with the south. Industries include the production of cement, cotton textiles, glass, and shoes, and there is tanning and food canning.

Shkodër was probably an Illyrian capital during the 1st millennium B.C. and is mentioned as such by Livy. At the partition of the Roman Empire the town passed to Byzantium, and later to the Bulgars, Serbs, and Venetians. After the Serb Stephen Dushan's death in the 14th century it became the capital of George Balsha, prince of Zeta (or Zenta), and was sold by his family in 1396 to Venice. It was a stronghold of Skanderbeg in the 15th century. The Turks laid violent siege to it in vain in 1473 and again in 1478; but after the latter siege Venice ceded it to Turkey and the valiant citizens of Shkodër were evacuated to Italy. The Bushati family took control in the 18th century, but in 1829 the Turks made it the capital of a vilayet (administration division). In 1912–13 it was besieged by the Montenegrins but was then taken over by an international brigade. Occupied by Austria in 1916–18, it was then controlled by Allied forces until reunited with free Albania in 1922. After 1944 it was for a time the main centre of resistance to the Communist government.

Lake Shkodër, 143 sq.mi. (370 sq.km.) in extent and mainly shallow, is divided between Albania and Yugoslavia. It has a fine rugged mountain setting, and fishing is locally important.
(D. R. O.-H.)

SHMIDT, OTTO YULIEVICH (1891–1956), Russian scientist and polar explorer, was born on Sept. 30 (new style Sept. 18, old style), 1891, at Mogilev. He was a university teacher of mathematics before and immediately after the Revolution of 1917. His support for the new regime and his administrative ability caused him to be appointed to various senior civil service jobs: he was manager of the state publishing house, deputy head of the central statistical administration and a member of the state

planning commission. After taking part in the Soviet-German Pamir expedition of 1928, he became interested in the arctic and went on an expedition to Franz Josef Land in 1929. Next year he was made director of the Arctic institute and in 1932 first head of the chief administration of the northern sea route (Glavsevmorput), the newly formed government department responsible for arctic development. During his six years in this job he directed the extensive Soviet program of exploration and exploitation of arctic resources, and generally spent the whole of each summer season aboard an icebreaker off the north Siberian coast. He led the expeditions in the "Sibiryakov" (1932) and "Chelyuskin" (1933–34), the establishment of the north pole drifting station (1937) and its relief (1938). In 1939 he left arctic work and devoted himself to science for the rest of his life. He had been elected an academician in 1935 and vice-president of the Academy of Sciences in 1939. On his initiative the academy created the Institute of Theoretical Geophysics in 1938. He was its director until 1948, advancing at this time a new theory of the origin of the earth. He was chief editor of the *Great Soviet Encyclopaedia* from 1924 to 1941 and of the journal of popular science, *Priroda*. To this remarkable record of activity he added a professorship of mathematics at Moscow University from 1926 until his death, becoming in this capacity the founder and leader of the Moscow school of algebra. His publications were mainly mathematical papers and articles on polar work. His influence on Soviet life and thought was both considerable and remarkably diverse. He died in Moscow on Sept. 7, 1956. (T. E. A.)

SHOA, the central province of Ethiopia, and the site of residences of the Ethiopian kings. Pop. (1961 est.) 2,500,000, largely of mixed Galla-Amhara stock. The province comprises mostly high plateau country rising to 13,123 ft. (4,000 m.) in Abuya Myeda, but the eastern and southeastern boundaries are in the Great Rift Valley along the Awash River. The hydroelectric plant at Koka on that river, 60 mi. (97 km.) S of Addis Ababa, was designed to provide power for the industrial development of the province. Stock is raised; cereals, vegetables, coffee, and tobacco are the chief crops. Roads from all parts of the country converge on the province; and a metre-gauge railway runs eastward from Addis Ababa, linking it with Djibouti in French Somaliland. The important centres are Addis Ababa (*q.v.*), the Ethiopian and provincial capital; Debra Birhan; Fiche; Nazareth (Hadama); Debra Libanos, a monastic centre; and Ankober, the former capital of the Shoa kingdom.

Shoa was the residence of the Ethiopian kings from the mid-10th century to the end of the 14th century. The actual sites of the royal residences have not yet been accurately located although they are named and described on contemporary maps. In 1528 Shoa was overrun by Muslim invaders from the state of Adal to the east and the ancient cities were destroyed. For over a century afterward Shoa was penetrated by the Galla peoples from the south who moved into the political vacuum left in this region and established themselves in farming communities as far north as the Blue Nile Valley. In 1856 Shoa was incorporated in the Ethiopian Empire by the emperor Theodore II, but Menelik II regained his kingdom of Shoa and in 1886 chose the site for Addis Ababa, his future capital. Building began at once and when Menelik became emperor of the whole country in 1889 Addis Ababa became the capital of Ethiopia. *See* also ETHIOPIA: *History*. (G. C. L.)

SHOCK is the medical term for an acute condition usually marked by weakness, profound depression, and pallor. The skin becomes moist, cold, and grayish. The pulse is rapid and weak. The blood pressure usually is below normal. Breathing is shallow. Urination is suppressed or stopped. If the patient has sufficient strength, he may be restless, but frequently he can be aroused only with great difficulty. The metabolic rate is low and there is suppression of all vital functions, so that the patient is obviously gravely ill.

The term shock was first used in the 19th century to characterize the alarming symptoms known to result from a wide variety of causes, both physical and psychic. Such an uncritical use of the term robbed it of significance, but the term persisted. Qualifying words indicating the probable cause of the condition are now usually employed; *e.g.*, traumatic, postoperative, anaphylactic, histamine, transfusion, etc. In the last analysis, death from almost any cause may be preceded by a number of symptoms characteristic of shock; therefore consideration of the condition usually is limited to collapse resulting from hemorrhage and from various forms of physical trauma (injury).

Traumatic shock was classified by W. B. Cannon into two types, primary and secondary. The primary type was defined as the collapse occurring immediately after severe injury and was considered as indistinguishable from syncope (fainting) and collapse. Secondary shock was defined as collapse occurring after a variable period of time following severe injury.

Medical authors make little distinction between shock and collapse or syncope, except to recognize that if collapse or syncope persists, shock will result. According to V. H. Moon, the attempt to distinguish between shock and collapse is like distinguishing between breeze and wind. He defined shock as "a disturbance of fluid balance resulting in a peripheral circulatory deficiency which is manifested by decreased volume of blood, reduced volume flow, hemoconcentration and by renal functional deficiency." N. E. Freeman defined it as "the clinical condition characterized by progressive reduction in circulating blood volume due to increased capillary permeability." H. N. Harkins defined shock as "an oligemia [decreased volume of blood] *initiated by* traumatic local fluid loss, either whole blood, plasma, or both; *accompanied by* decreased cardiac output, diminished volume flow, lowered venous pressure, decreased oxygen consumption, arteriolar vasoconstriction, progressive hemoconcentration, capillary congestion, acapnia [diminished carbon dioxide in the blood], and secondary blood pressure fall; and *perpetuated by* a summation of these factors and possible hyperpotassemia [increased blood potassium], increased generalized capillary permeability, anoxia [lack of oxygen], action of tissue metabolites, and deficiency of adrenal cortical hormone." Harkins also pointed out that "other changes, both chemical and pathologic, may occur in shock, including increased blood nonprotein nitrogen, decreased coagulability of the blood, and in some instances increase in plasma magnesium."

In a summation of a 1961 conference on shock, J. E. Rhoads concluded that the definitions offered by most of the participants would be encompassed by considering shock as "a default in the transport mechanism of the body generally affecting vital cells." The default, when absolute, is the irreversible shock of the physiologist; when relative it is the reversible shock syndrome so important for the clinician. This definition would allow the inclusion of hypovolemic (decreased volume of circulating fluid) and cardiac shock as well as that due to partial respiratory obstruction, uremia, and at least the late phases of neurogenic and septic shock (associated with vasodilatation resulting from, respectively, nerve action and toxic conditions).

Cannon and W. M. Bayliss developed the so-called traumatic toxemia theory to account for the initiating factor of shock. According to this theory, a toxic substance is absorbed from the injured tissues and distributed to all parts of the body, where it injures the capillaries which in turn allow fluid to leak through them to such an extent that the volume of circulating blood becomes inadequate. In view of the fact that histamine (*q.v.*) or histaminelike substances had been demonstrated in animal tissues and that shock had been produced experimentally by injections of this substance, the toxemia theory was readily accepted. It was called into question, however, by A. Blalock and by E. Parsons and D. B. Phemister; though weakened, it was not abandoned.

There is substantial agreement among authorities that loss of blood, blood plasma, or body fluids by whatever means is the most important initiating factor in shock of most types. Hemorrhage, excessive sweating, vomiting, dehydration, diarrhea, injury to the body, low blood pressure, cold, pain, and psychic stimuli such as fear and grief predispose the individual to shock, since any one of these, if sufficiently severe and prolonged, may result in reduction of the volume of circulating blood. Some of the results of this are known, such as increased capillary permeability after anoxia, but others have been only surmised. Clearly, reduction of the circulating blood volume causes anoxia of the tissues, in

turn causing injury to the capillaries which permits further loss of plasma volume. This cycle, if uninterrupted, becomes irreversible, and death is certain.

Treatment.—Treatment of shock depends to some extent on the nature of the injury or disease responsible for its development. Attention is first directed to the loss of blood or other body fluids, and steps are taken to prevent further loss. Hemorrhage, vomiting, sweating, and diarrhea are controlled as soon as possible, and pain is relieved. In case of severe injury of the extremities, the part is immobilized. Rest and quiet are recommended as soon as the patient has been made reasonably comfortable. Prevention of further loss of body heat is accomplished by use of covers, hot-water bottles, and heating pads, but overtreatment should be avoided. Elevation of the foot of the bed may be helpful. Vasoconstrictor drugs are not indicated as a routine treatment but may be of benefit in exceptional cases such as so-called spinal shock. In cases in which pulmonary ventilation is inadequate for saturation of the blood, oxygen is administered. Operations in the presence of shock are done when possible with local-acting or short-acting drugs such as pentothal sodium or hexobarbital. If the presence of shock is thought to be owing to bacterial infection, antitoxins or antibiotics are employed.

Since the fundamental factor in the production of shock is decreased volume of circulating blood, the best treatment of the condition is the transfusion of whole blood or blood plasma, but if these are not available appropriate doses of solution of acacia, pectin, dextran, or other blood substitute should be injected. Isotonic solutions of sodium chloride and glucose are recommended for temporary use until more adequate measures can be instituted.

Prevention.—In hospitals prevention of shock is of paramount importance. Patients who have lost large amounts of blood are prepared for operation by adequate transfusion. Those who have become dehydrated receive fluids by infusion or are given proper quantities of fluid by mouth. Preparation of intravenous administration of fluids is routinely made before the operation begins; at the first sign of deficient circulation, fluids are supplied to the patient. In case of severe hemorrhage during the operation, blood is administered in sufficient quantities to prevent the occurrence of shock.

For "shell shock"—a use of the term outside the scope of this article—*see* COMBAT FATIGUE. *See* also references under "Shock" in the Index.

SHOCK ABSORBER, a device for controlling the motion of an elastic suspension system such as that of a vehicle. The spring elements of such a suspension system are deformed by an impulse applied to the wheels and tend to react after the force of the impact is spent. Shock absorbers slow down the vibratory motion of the suspended portion and quickly restore equilibrium.

Modern shock absorbers are hydraulic devices and are double acting in that they oppose both the compression of the springs and the rebound. The direct-acting or strut type (*see* figure) is attached to the vehicle frame and axle by two eyes. The central tubular cylinder is fitted with a piston that is attached by a piston rod to the upper eye. The cylinder moves with the lower eye and an annular fluid reservoir surrounds it. A spring-loaded one-way seal prevents fluid flow downward past the piston, but permits controlled flow upward. A valve in the under side of the piston controls the rate at which fluid can flow from the chamber during rebound. The fluid reservoir communicates with the compression chamber through two spring-loaded valves in the base of the cylinder. The discharge valve at the right controls the rate at which fluid can escape from the cylinder during a compression stroke and the valve at the left later refills the cylinder. Relative motion of the sprung and unsprung portions of the vehicle

CROSS SECTION OF HYDRAULIC SHOCK ABSORBER

can be only as rapid as the reciprocation of the piston in the shock absorber, which can be no faster than the fluid flow from one compartment to another permits. Controlled resistance to fluid flow limits the rate at which the suspension can vibrate.

Shock absorbing mountings are used to isolate the vibration of machines, such as diesel engines. These mountings usually employ some resilient member, such as blocks of cork or rubber, interposed between the engine and the floor on which it rests.

Large calibre guns are fitted with recoil mechanisms that permit the gun barrel or the breech to move back under the reaction to the acceleration of the missile. This movement is gradually stopped by a hydraulically damped spring that returns the parts to their operating position.

See VIBRATION CONTROL. (O. C. C.)

SHOCKLEY, WILLIAM BRADFORD (1910–), U.S. physicist, Nobel Prize co-winner for physics in 1956 with John Bardeen and Walter Houser Brattain (*qq.v.*) for work on the transistor (*q.v.*). Shockley was born in London of U.S. parents Feb. 13, 1910. Reared in California, he was educated at California Institute of Technology (Pasadena) and Massachusetts Institute of Technology (Ph.D., 1936).

He joined the technical staff at the Bell Telephone Laboratories in 1936, and there began experiments that led to his invention and development of the junction transistor. During World War II he served as director of research for the Antisubmarine Warfare Operations Group of the U.S. Navy and as expert consultant for the office of the secretary of war. After the war he served as director of transistor physics research for Bell. He was visiting professor of physics at the California Institute of Technology in 1954, deputy director of the Weapons Systems Evaluation Group

of the Department of Defense in 1954–55, and joined Beckman Instruments, Inc., to establish the Shockley Semiconductor Laboratory in 1955. In 1958 he became lecturer at Stanford University, and in the 1960s was director of the Shockley Transistor Unit of the Clevite Corporation in Palo Alto, Calif.

See S. Thomas, *Men of Space*, vol. 4 (1962).

SHODDY, originally probably a mill term referring to the wool waste thrown off during the processing of wool, now a term given to the fibres reclaimed from wool cloths. The reclamation consists of reducing the cloth to the fibrous state by a tearing-up process called "shoddy picking" or "garnetting." The resulting product is deficient in fibre length and strength and is usually mixed or blended with fleece wool or some other fibre before being respun. In the United States reclaimed wool used in consumer products must be identified on the label as either "reused" or "reprocessed." (C. P. MA.)

SHOEBURYNESS, a promontory on the Essex coast of England, 4 mi. E of Southend-on-Sea, and the point at which the coastline trends northeast from the estuary of the Thames. It has a gunnery testing establishment. On the seaward side of the Ness is an earthwork attributed to the Norsemen.

SHOES and boots, worn as protective footwear, are ancient items of dress. In early civilizations shoemaking skills were developed to a high degree; styles and variety were produced by the artisan, but the process was slow and expensive. Modern mass production depended upon the development of shoe machinery, which began about the middle of the 19th century, and the industry logically developed most extensively in the more highly industrialized nations. In the 1960s the United States alone produced and consumed more than 25% of the world's leather footwear—an average of 3½ pairs per person annually. It is estimated that purchase of about half of these was for replacement or utility; that of the other half was motivated by the appeal of fashion. Women's dress shoes are influenced by fashion to a greater extent than are other types, and in the United States about 47% of all shoes manufactured are women's shoes. (The remainder consists of men's shoes, 17%; children's shoes, 23%; slippers, 12%; athletic and other specialized types, 1%.) Somewhat similar figures apply in Great Britain, another leading producer of leather footwear, although the consumption rate is slightly lower—just over three pairs per person. Per capita consumption and spending for footwear is also directly related to personal or family income (except that high-income families spend proportionately less on all clothing, including footwear, than middle- and low-income families).

CONSTRUCTION AND DESIGN

History.—The first type of footwear was a simple wraparound of leather (the basic construction of a moccasin), held together on the foot with rawhide lacings. Gradually this design was improved upon and assumed many variations. Another early design was the simple sandal, consisting of a sole held on the foot by a leather thong. The oldest shoe now known is a sandal made of woven papyrus, found in Egypt and dating from about 2000 B.C.

Moccasins, sandals, and simple boots were the prevailing types of footwear almost up until the Middle Ages. Wooden clogs or shoes, commonly used by the poorer classes, were also important, though distinctly different from the more desirable leather types. Until modern times footwear was largely homemade, though a considerable share was produced by artisans and craftsmen; large guilds of shoemaking specialists date back to ancient Rome. While there were small shoemaking shops consisting of a few craftsmen, the first signs of the "mass-production" factory did not appear until the 18th century. The first shoe factory in the United States is credited to John Adams Dagyr, a Welshman who opened a shop in Lynn, Massachusetts colony, in 1760. He employed a number of shoemakers, each performing only one operation, who produced shoes that could be purchased directly from stock. Previously, most purchased shoes were custom-made.

In 1818 lasts (wooden forms) for shaping shoes were made in rights and lefts. Another milestone was reached in 1846 when Elias Howe invented the sewing machine. Previously, the majority of shoes were made by attaching the sole to the upper part with tacks, nails, or wooden pegs; any sewing was done by hand. The sewing machine not only greatly speeded production but made a better shoe. Shortly after, and over the next 60 or 70 years, a steady flow of new and improved shoe machinery was introduced, and by the beginning of the 20th century the shoemaking industry was on a full mass-production basis.

Materials.—Since time immemorial the universal basic material for shoes and boots has been leather, used for uppers, linings, counters, inner soles, outer soles, welting, and other parts. Though still dominant, leather is being replaced by other materials, particularly in the component parts of shoes. For example, most inner and outer soles are now made of nonleather materials, such as rubber, man-made fibres, or composition materials. Other parts of the shoe are also being made of nonleather materials, such as plastic welting and plastic heels, coated fabrics for linings, natural and coated fabrics for uppers, plastic counters or back-part stiffeners, and chemically compounded box toes. Most of these materials, the products of modern chemistry, are priced lower than leather and at the same time meet all required performance standards.

Each type of leather commonly used in shoe uppers and linings has its distinctive characteristics, and each tends to find its own specialized applications in footwear. Calf is the "luxury" leather, used in the finest grade men's and women's shoes. Side leather (made from cattle hide, and called "side" because the large hide is cut down the middle, lengthwise, into two sides for easier handling) is the most versatile of all shoe leathers. It comes in several grades and is used for a great variety of footwear—women's lightweight casual footwear, children's school shoes, and other kinds. An estimated 70% of all leather used in shoe uppers is side leather.

Kid leather, made from goatskin, also has wide use, ranging from women's high-grade dress shoes to men's comfort shoes. Sheepskin is used largely in slippers and linings. Reptile leathers (alligator, lizard, and snake) are used in some women's and a few men's shoes. Cordovan (from horsehide—a small "muscle" layer in the hide) is a heavy leather popular in men's shoes. Certain specialized leathers such as kangaroo (used in comfort and athletic shoes), ostrich (used in a few women's shoes), and pigskin also find application.

Patent leather, usually made from cattle hide, is given a special surface finish. Suede is made from any of several leathers (calf, kid, cattle hide) by buffing the inner surface to create a napped finish.

Certain fabrics, including linen, satin, and silk, have found increasing use in footwear. Another modern development has been coated fabrics, consisting of a fabric base coated with a chemical surface finish to give a vast variety of textures and designs, many of them simulating leather grains to a remarkable degree. These find wide use in less expensive shoes, especially in women's and girls' footwear. Man-made fibres are producing new families of materials, such as nylon mesh and nylon velvet. Much synthetic patent and suede is also produced for shoes.

Some of these leathers and other materials are used for linings as well as for outside uppers of shoes.

Styling and Design.—Many kinds of footwear—men's work shoes, oxfords, and riding boots, for example—remain essentially unchanged from year to year, but in other types fashion plays a considerable role. Each year new styles are prepared to conform with the seasonal turnover and the general trends of fashion. In the U.S. it is estimated that more than 100,000 new sample styles are prepared annually by the manufacturers. After the retailers have made their selections, about 20 to 25% of the original samples will go into production.

Most manufacturers design their lines twice yearly, for spring-summer and fall-winter. Some designing is done for one brief season, such as summer, or for resort-cruise wear. The greatest demand for variety of style is in women's shoes, followed by men's and girls' shoes. Seasonal turnover in women's styles is quite pronounced, while in men's shoes it usually requires several seasons before distinct changes take place.

Determining the styling features to be incorporated in a new season's line is a highly complicated procedure. In women's shoes, for example, consideration must be given to colours, materials, lasts, patterns, ornamentation, silhouettes, heel shapes and heights, textures, and surface finishes. These must be welded into a "line" of scores of different styles for the new season, and they must be attuned to general fashion trends in women's apparel, for shoes are regarded as the most important accessory in a woman's ensemble.

Styling a new line involves an expert team of specialists: the designer, fashion coordinator, style man, sales manager, sales staff, and pattern man. New lines are usually prepared from 4 to 12 months ahead of season. New styles or style trends in footwear are usually initiated by the makers of higher-grade, higher-priced shoes. Once a new shoe is launched and receives the first signs of consumer interest, it is immediately adopted by the volume, or medium- and lower-priced, shoe lines.

After about 1945 in the U.S., juvenile footwear, particularly in girls' shoes, moved toward "fashion." While the conventional school oxford remained a basic shoe, a wide variety of new types and styles of shoes won increasing favour.

Methods of Construction.—There are said to be more than 800 ways in which to make a shoe, but only a few of these are actually used. Fundamentally, shoe construction consists of attaching the sole to the upper in such a way as to create a bond sufficiently durable to withstand the wearing conditions for which the shoe was designed. There are four basic construction methods:

1. Sewing, which includes such types as the Goodyear welt process, in which the sole is sewed to a welt strip that has previously been sewed to the upper and insole, and the stitchdown, in which the upper is turned out and stitched down to the sole.
2. Cementing, in which the outer sole is attached to the insole and upper by adhesives.
3. Molding, in which the sole is vulcanized or "molded" to the upper.
4. The use of fasteners, as in nailed or stapled shoes.

There are numerous variations within each classification, and special features of one process may be combined with special features of another to provide a sort of "crossbreed" construction.

Each kind of shoemaking has distinctive features that make it particularly adaptable to certain kinds of wear. For example, the Goodyear welt process, known for its sturdiness, is commonly used in men's and boys' dress shoes as well as in better-grade children's shoes of certain types. Cement construction enables shoes to be built on lighter, sleeker lines and is therefore used for most women's and many girls' shoes and for some lighter types of men's shoes. Molding, as in the vulcanized process, combines economy of construction with rugged durability and is used in men's work shoes and in some juvenile footwear. It is also used in all rubber-canvas shoes.

About 80% of all shoes manufactured in the U.S. are made by three processes: cement (54%), Goodyear welt (19%), and stitchdown (7%). Trends or shifts in the use of certain shoe constructions are motivated by technological changes, economics, and fashion. The cement process was launched commercially in the early 1930s and by the 1960s was used in over half of all shoes made in the U.S. The Goodyear welt was still regarded as one of the best methods but had steadily declined from its once dominant position. Market demand for lighter shoes and the proportionately higher number of women's shoes manufactured partially account for this. Differences in manufacture are also significant. In most basic constructions about 150 different operations are required to make a shoe, and as many as 200 may be required. Certain modern methods of construction, such as the vulcanized and injection-molding methods, have been well received because they reduce both the number of operations required and the number of component parts. In Great Britain, for example, one-fifth of all the footwear made at the beginning of the 1960s was produced by these methods, and the proportion was increasing.

Steps in Production.—Shoe manufacturing is essentially an assembly process of fusing together a number of components: heel, sole, counter, upper (vamp and quarter), lining, toe box, welting, insole, ornamentation, and the like. A great variety of machines and devices, each for a specialized operation, is utilized. Each style or type of shoe has its own preplanned schedule in moving through the production line. Operations and machines must be adjusted differently for different styles or types of shoes or even when different materials are used.

The individual components of a shoe are usually purchased by the shoe manufacturer from outside suppliers. These components (linings, soles, insoles, counters, heels, etc.) are purchased according to specifications for size, weight, grade, colour, finish, etc., all to be assigned to a particular style or type of shoe.

Each specialized construction has its distinctive procedures, but there are certain essential features common to all constructions. The major steps in shoe construction may be briefly outlined as follows:

The cutting room is the launching point in the shoemaking process. Here the upper materials and linings are cut out with dies that have been designed especially for that particular shoe, but for short production runs the older method of hand cutting around templates is still retained. The dies are used with clicking or cutting machines, and the weight and cutting edge of the die must be accommodated to the particular type of material being cut. Special machines are also used to perforate the upper material or emboss it with a particular design. Splitting machines (for reducing the thickness of a material) or crimping machines (for preforming leather parts) may also be used in the cutting room.

The shoe then moves to the fitting (or closing) room where the precut parts of the upper are fitted together, usually by sewing or stitching, although some cementing is done. This assembly includes the upper portions of the shoe, linings, stays, facings, eyelets, etc. Many types of sewing machines are used, some of them attaining speeds of more than 4,000 rpm and able to sew from one to eight rows of stitching at one time.

As the shoe moves out of the fitting room in preparation for the important lasting operations, it begins to take shape. The assembled upper, in loose form, is ready to be fitted over the wooden last for which the patterns were precisely designed. First, however, the insole is placed on the bottom of the last. This insole, of a shape and size to conform exactly to the bottom of the last, is a sort of "security layer" between upper and outer sole to fuse the shoe parts into a firm unit. The counter or stiffener at the back part of the shoe is placed between the lining and outside of the upper. These parts—insole, counter, and upper—are now on the last, and the entire unit is presented to the assembling machine.

In lasting operations ingenious mechanisms grip the upper at the toe and sides with pincers, pulling the leather tightly over the wood last so that the material conforms in minute detail to the whole fore part of the last. The heel or back part of the shoe is also lasted.

After lasting, however, a number of operations are required to prepare the shoe for bottoming. It is at this point that some of the essential differences between the various types of shoe constructions are evidenced. The Goodyear welt, cement, stitchdown, and vulcanized constructions enter the sole-laying stage under different sets of prepared conditions. Also, the method by which the sole itself is attached is distinctly different. Once the sole is attached it must still receive finishing touches, such as trimming, staining, and burnishing the edges. The bottom of the sole must be cleaned or buffed and polished.

Applying the heel is an equally meticulous operation, done with special heeling machines. These attach the heel with nails; in the case of high heels, a long screw goes down into the heel for added security. Once the heel is attached, it also undergoes trimming and finishing operations.

The final series of operations consists of applying heel or sock linings, inserting laces, attaching buckles to a strap, and brushing or polishing. Finally there is a thorough inspection, and the shoes are then ready for packing and shipping.

Boots are made in much the same way, the major differences being in the lasts, which generally have a bootlike shape, and in the patterns for the uppers. The type of construction depends upon the type of boot; for example, a work shoe or boot might

be made by a vulcanized process while a riding boot would be made by a Goodyear welt process.

THE FOOTWEAR INDUSTRY

United States.—*Industry Structure.*—In the 1960s there were about 850 shoe-manufacturing firms in the U.S. The leading 10 firms accounted for 30% of the total production; the leading 30 firms for 42%; and the top 80 for more than 54%. Though shoe production has shown a steady gain (averaging about 10,000,000 pairs a year increase), the number of shoe-manufacturing firms continues to decline, marginal firms being eliminated under the duress of competition and capital requirements.

New England accounted for about one-third of the nation's shoe production, with Massachusetts the leading state, representing 17% of all shoe output. Other major shoe-producing states were New York and Pennsylvania, each with 14%; Missouri, 10%; and Ohio, Tennessee, Wisconsin, and Illinois, each averaging between 3% and 5% of the total.

Unlike shoe factories in most other countries, American plants are highly specialized, making only men's or women's or children's shoes or slippers, with further specialization in grades or price lines produced. The American shoe worker averages an output of about 2,900 pairs a year, the highest productivity level in the world. Factories tend to be medium sized. The best efficiency level is found to be at a production rate of between 4,000 and 10,000 pairs a day. The largest shoe-manufacturing firm produces over 200,000 pairs a day, but this is distributed over some 50 different plants. Most shoe factories are located in smaller communities rather than in large cities or heavily industrialized areas.

Retailing and Marketing.—Approximately 850,000,000 or more pairs of footwear (including rubber footwear and imports) are sold in retail stores annually in the U.S. Slightly over half of these are sold through shoe stores. The rest are distributed through various types of retail establishments—department stores, mail-order and variety store chains, clothing stores, general merchandise stores, discount houses, and even drugstores. About 71% of all shoes are sold in only 13 states, and 44% are sold in only 5 states (New York, California, Ohio, Illinois, and Pennsylvania). New York alone accounts for 14% of all shoe sales.

The annual dollar volume for the average shoe store is below $75,000. Shoe retailing is a relatively complex function, involving not only the basic inventory and operating requirements of any retail establishment but also consideration of fashion, foot health, fitting, and other specialized requirements. For this reason it is a higher-risk business than comparable retail stores in other fields. The seasonal turnover of styles, for instance, necessitates astute judgment to hold losses on wrong selections to a minimum. In women's shoes, careful selections must be made in terms of colours, heel heights, patterns, etc.

Shoe fitting is an extremely important function in the shoe store and requires experience and judgment combined with highly specialized knowledge and training; badly fitted shoes do not wear well, feel uncomfortable, and constitute a health hazard (*see* FOOT, DISEASES AND DISABILITIES OF). In addition to size (length and width), fitting involves the proper adaptation of shoe to foot in terms of leathers (some have more "yield" than others), lasts, heel heights, gait characteristics, etc. The store must carry a large and costly inventory to fit the vast variety of feet it must service, to say nothing of the customer's desires in style. A shoe factory may produce as many as 140 different sizes on a single style of shoe. A shoe store may carry as many as 65 sizes on a single style and have only one pair in each size. It would require duplication of sizes in the more popular ranges. A store may carry 50 to 100 different types and styles of shoes, and it can readily be seen that the problem of inventory and risk is extremely complex.

After 1945 there were some important changes in shoe retailing trends in the U.S. One change was in the locations of shoe stores, many of which are now situated in suburbs and shopping centres and even as "free-standing" stores on highways. A considerable amount of shoe business is done outside the downtown districts. Certain types of outlets formerly not associated with shoes have gone increasingly into the business. Among these are supermarkets, discount stores, variety stores, some drugstores, and various general merchandise stores. Another trend has been toward "self-service" shoe stores with interior layouts where customers can browse and shop. These are called self-selection layouts but are accompanied by fitting services.

Another change, particularly after the mid-1950s, was in the amount of footwear imported into the U.S. In 1954 leather shoe imports amounted to about 7,700,000 but by 1962 reached over 55,000,000 pairs. Rubber footwear imports showed an even more spectacular gain—from less than 1,000,000 pairs in 1954 to 100,000,000 pairs in 1961. These gains in footwear imports were expected to continue through the 1960s, though perhaps at a slower rate. Principal sources were the United Kingdom, Italy, Japan, and Hong Kong; except for rubber footwear, most of the imports were men's and women's shoes, chiefly in the lower price lines.

U.S. manufacturers have given only token effort to the exporting of shoes. For many years before and after World War II shoe exports remained around 4,000,000 pairs a year and by the early 1960s had dropped to around 3,000,000 pairs.

The U.S. shoe industry as a whole continues to show steady though rarely spectacular growth. It is known as a "stabilized" industry, not subject to sharp increases in times of prosperity or sharp declines in times of recession or slump. Its production and sales growth pattern is closely related to population growth and to a lesser extent to income growth, with some proportionate increase in consumer spending for shoes. (WI. A. R.)

Great Britain.—In the early 1960s there were some 1,200 shoe-manufacturing firms in the United Kingdom, but a third of these were very small, employing under 20 workers. As in the U.S., there was a tendency for manufacturing units to become fewer and larger, but shoemaking, as compared with other industries, was still one of small-size factories, only five employing more than 1,000 workers. Almost equal numbers of men and women were employed, and piecework was common.

After the U.S., Great Britain is one of the world's largest footwear producers. The main centres of production are Leicestershire and Northamptonshire, traditional shoemaking areas where originally cattle and sheep were plentiful (for hides and skins) and the country was well wooded with oak (for bark-tanning). Northampton is world renowned for its high grade of men's footwear, and Leicester has developed into a centre for medium-grade women's shoes. High-grade fashion shoes are made in Norwich and London, and these two centres also manufacture children's shoes. Southwest England, once the centre for heavy boots for miners and agricultural workers, has developed as the main centre for molded footwear and good-quality women's and children's shoes. The Rossendale Valley in Lancashire is noted for its slipper production. The tendency for larger manufacturing units accentuated the trend toward greater specialization as regards type and price of shoe produced in different firms and areas.

Although the labour force in the industry steadily decreased (in the early 1960s it was about 100,000 compared with 115,000 a decade earlier), improved techniques and machinery raised productivity, and after World War II total output rose steadily by an average of 3,000,000 pairs a year. In 1960 the industry produced nearly 160,000,000 pairs of leather footwear (*i.e.,* excluding rubber), of which some 40% was women's shoes while men's and children's shoes and slippers each accounted for about 20%.

With financial support from the government, the industry maintains an efficient research station (British Boot, Shoe and Allied Trades Research Association). Besides laboratory research it offers to its members consultancy services on practical problems and acts as independent arbiter on matters concerning consumer complaints.

Retailing and Marketing.—The end of the 1950s saw a spectacular rise in consumption of footwear in Great Britain, largely because of the growing "teen-age" market and a general increase in consumer expenditure on clothing and footwear. Speedier changes in fashion, particularly in women's shoes, also caused the buying public to spend more on shoes, but these changes brought new problems for manufacturers and retailers alike. Total consump-

tion of leather footwear in 1960 amounted to more than 160,000,000 pairs (or more than 3 pairs a person), and rubber footwear purchases made up a further 40,000,000 pairs, the overall value being £290,000,000.

Multiple retail organizations (covering 7,700 outlets) sold 45% of this footwear, and independent retailers (comprising 5,900 outlets), 26%. Cooperatives, department stores, mail-order and credit trading concerns accounted for 5–6% each. Some 20–25% of British footwear was retailed under manufacturers' brand names, but the great majority of shoemaking firms produced anonymously to orders from wholesalers and retailers.

Domestic production only partially satisfied the increased consumption, and imports of leather footwear rose from 2,500,000 pairs in 1955 to 14,500,000 in 1960, when one in every 11 pairs sold came from abroad. Most of these came from Europe, with Italy and France predominating, and were mainly women's shoes and slippers. Imports of rubber footwear also rose, with Hong Kong traditionally the largest supplier.

British footwear was exported to more than 100 overseas markets, and in 1960 some 9,000,000 pairs of leather footwear worth £12,000,000 were sent abroad, nearly half of them being men's shoes. The biggest single market was the U.S., taking practically one-third of Britain's footwear exports; one-half went to the Commonwealth and one-sixth to Europe. The Commonwealth countries, however, were a diminishing market for British shoes, as quantitative restrictions were imposed to protect the growth of the young, local footwear manufacturing industries. As old markets contracted, new ones opened up, and 1959 saw the start of a flow of British footwear exports to the U.S.S.R.

Western Europe.—Besides Great Britain, the main footwear producing countries in Europe are Germany, France, and Italy. Italy's output rose conspicuously during the 1950s, trebling itself between 1954 and 1959. Italy also became the leading European exporter of footwear, accounting for 40% of the continent's exports of leather footwear. This success was due to the development in Italy of an elongated, lightweight styling of shoes that proved extremely popular. All the European countries experienced a rise in consumption of footwear in the 1950s, and all, except Norway, increased their output. The emergence of the European Economic Community (EEC) and the European Free Trade Association (EFTA) led to greater trading in footwear between the countries concerned. On the retail side the main outlets were independent shops and department stores; multiple organizations were not developed to the degree they had in Great Britain, but buying groups began to be established by retailers. Both the EEC and the EFTA had their own liaison committees of manufacturers' organizations, and the Organization for Economic Cooperation and Development hides and skins committee compiled production and trading statistics on footwear in their member countries to encourage greater coordination of footwear production and marketing in this area. (P. G.-Sm.)

U.S.S.R.—Footwear is produced in large factories, usually with long runs on the same style. Workmanship and finish have often been poor, but in the 1960s research on automatic transfer lines and multioperation machines for mass-produced, cheap, serviceable footwear was being carried out. In 1964, 474,000,000 pairs of leather footwear were produced, utilitarian styles being sold with guaranteed lengths of life. In the early 1960s more than half the imported footwear was from Czechoslovakia and most of the remainder from other European countries. Smaller quantities were imported from India and the People's Republic of China.

SHOFAR, the ancient ram's horn of the Israelites, is a natural horn that has been bent upward at the wide end and partially flattened from end to end. It can be made to produce sobbing, wailing, and sustained sounds in sequences that are varied strictly according to ritual. In the Pentateuch the use of the shofar is prescribed for the New Moon and other festivals. In modern Jewish liturgy it is sounded in the synagogue on Rosh Hashana (New Year) and Yom Kippur (Day of Atonement) as a call to repentance and sacrifice, love of the Torah, and hope in the messianic future.

SHŌGI is a Japanese form of chess (*q.v.*), the history of which is obscure. Traditionally it is thought to have originated in India and to have been transmitted to Japan via China and Korea.

Shōgi, like chess, is played on a squared board with pieces of varying powers, and the ultimate object is the checkmate of the king. Two distinctive features, however, differentiate shōgi sharply from European chess: (1) captured men are not "dead" but may be replayed as part of the captor's forces; (2) there is no pawn chain or blocked pawn position. Each player has 20 men, which oppose each other on a board composed of nine horizontal and nine vertical rows. There are nine pawns (*fu*), a rook (*hisha*) and a bishop (*kaku*), one king (*ōshō*), two gold generals (*kinshō*), two silver generals (*ginshō*), two knights (*keima*) and two spearmen (*kyōsha*). From the standpoint of mobility, *hisha* and *kaku* roughly correspond in chess to the queen, *kyōsha* to the rook, *kinshō* and *ginshō* to the bishop; the others are the same in both games. Rook and bishop oppose each other diagonally, the rest on the same file. The pieces are flat, blunt and slightly tapering toward the front. Each bears identi-

WOODEN SHŌGI CHESSMEN: JAPANESE, 20TH CENTURY

fying characters. Captive men are held at reserve bases until they are needed on the field again, hence the number of pieces in play remains approximately the same from the beginning to the end of the game. All men except the king and gold generals are promoted on entering the last three rows of enemy territory.

SHOGUN, abbreviation of *sei-i-tai-shogun* (barbarian-subduing generalissimo), was one of several titles under which early Japanese emperors commissioned supreme military commanders for campaigns against the Ainu of northern Japan. The title first appeared in A.D. 720 but lost its original meaning with the pacification of the north country in the 9th century. Minamoto Yoritomo (1148–99) first used the title as a basis for asserting military and political authority over the country. Yoritomo won military hegemony of Japan in 1185 and acquired imperial appointment as shogun in 1192. Together with other inheritable high court ranks and titles it provided the legal foundation from which his military headquarters (*bakufu*) exercised control over all military families in Japan. As the military class acquired increased powers over national and local affairs, the shogun became *de facto* ruler of Japan, though the emperor continued to retain formal sovereignty. Yoritomo's successors as shogun ruled from Kamakura (1192–1333). The second line of shogunal succession, begun by the Ashikaga family, ruled from Kyōto (1338–1573). The third line, established by the Tokugawa house, used Edo as its capital (1603–1867). With the intrusion of western powers into Japanese affairs in the 19th century, the question of definition of powers between the shogun (called "tycoon") and emperor (mikado) became an issue. In 1867 the Tokugawa shogun resigned his title and "returned" his prerogatives of civil and military administration to the emperor.

SHOLAPUR, a town and district in Maharashtra state (till April 30, 1960, in Bombay state), India, lies 140 mi. S.E. of Poona by road. Pop. (1961) 337,583. The town has two arts colleges and a college of commerce affiliated to Poona university. Its chief industry is the manufacture of cotton cloth in textile mills and on power and hand looms. Sholapur's convenient situation between Poona and Hyderabad, with which it is connected by the Central railway, has made it the centre for the collection and distribution of goods over a large area.

SHOLAPUR DISTRICT comprises an area of 5,809 sq.mi. with a pop. (1961) of 1,860,119. The population, predominantly rural, is engaged mainly in agriculture. The district is situated in the middle of an extensive plain 1,800 ft. above sea level and has a generally flat or undulating terrain. The main rivers are the Bhima and its tributaries, the Man, the Nira and the Seena (Sina). Sholapur is an important jowar-producing district. Paddy and bajra are the other principal food crops, although peanuts and cotton are slowly gaining in importance. The chief industries are spinning, weaving and dyeing. The main trade centre for cotton, oilseed and oil is Barsi (pop. 50,389), 37 mi. N. of Sholapur.

Pandharpur (*q.v.*), 33 mi. W. of Sholapur, is a famous place of pilgrimage and a popular centre for the worship of the god Vithoba, believed to be an incarnation of Vishnu. It has association with the great poet-saints of Maharashtra devoted to the Bhakti cult. Places of interest are the Hemadpanti temples at Barsi, Mohol, Malsiras, Pandharpur and elsewhere. There is also the tomb of a daughter of the emperor Aurangzeb at the village of Begampur. (M. R. P.)

SHOLEM ALEICHEM, pseudonym of SOLOMON RABINOWITZ (1859–1916), popular Yiddish classical author. Born in Pereyaslav, in the Poltava district of the Ukraine, on Feb. 18, 1859, he was educated for the rabbinate at nearby Varonkov. Drawn to writing as a youth, he became a private tutor of Russian at the age of 17, and at 18 went to the estate of Elimelech Loeff near Kiev to tutor his 12-year-old daughter Olga. He fell in love with her, an event that cost him his position. He served as a government rabbi in Lubin and when he was 21 married Olga. Her father's death in 1885 brought him a considerable fortune. His first writing had been in Russian and Hebrew, but between 1883, when his first story in Yiddish appeared, and his death he published over 40 volumes of novels, stories and plays in Yiddish. He used part of his fortune to encourage Yiddish writers and edited the annual, *Die Yiddishe Folksbibliotek* (1888–89); he lost the rest of it in business. His works were widely translated, and he became known in the United States as the "Jewish Mark Twain." He left Russia in 1905, established his family in Switzerland, and lectured in Europe and United States. At the outbreak of World War I he went to New York city where he died on May 13, 1916.

English translations from his *Verk*, 14 volumes (1908–14), include *Jewish Children*, translated by Hannah Berman, 3rd edition (1937); *The Old Country*, trans. by Julius and Frances Butwin, 3rd edition (1954); and *Adventures of Mottel, the Cantor's Son*, translated by Tamara Kahana (1953). He was the first to write in Yiddish for children. Adaptations of his work were important in the founding of the Yiddish Art theatre in New York.

See Maurice Samuel, *The World of Sholom Aleichem* (1943).

SHOLOKHOV, MIKHAIL ALEKSANDROVICH (1905–), Russian novelist, winner of the 1965 Nobel Prize in Literature for his "artistic strength and honesty when depicting a historical epoch in the life of the Russian people." He was born on May 24 (new style; May 11, old style), 1905, on a farm (Kruzhilin) in Veshenskaya, a Cossack village in the Don region of southern Russia. After joining the Red Army in 1920 and spending two years in Moscow, he returned in 1924 to his native village. He made several trips to Western Europe, and in 1959 accompanied Khrushchev to the United States.

Sholokhov began writing at 17, his first published book being *Donskie rasskazy* (1926; Eng. trans., *Tales of the Don*, 1961), a collection of realistic short stories. In 1925 he began his famous novel *Tikhi Don* ("The Silent Don"). The slow maturing of his work is remarkable: it took him 15 years to write *Tikhi Don* (four volumes, 1928–40; translated in two parts as *And Quiet Flows the Don*, 1934, and *The Don Flows Home to the Sea*, 1940) and 28 years to complete his other major novel, *Podnyataya tselina* (1932–60; translated in two parts as *Virgin Soil Upturned* [U.S. title, *Seeds of Tomorrow*], 1935, and *Harvest on the Don*, 1960). *Tikhi Don*, about the Don Cossacks before and after the Revolution, became the most widely read novel in the U.S.S.R.

See I. Lezhnev, *Mikhail Sholokhov* (1948); E. J. Simmons, *Russian Fiction and Soviet Ideology: Introduction to Fedin, Leonov, and Sholokhov* (1958).

SHONA is the collective name of more than 1,000,000 (in the 1960s) culturally similar Bantu-speakers of Negroid-Armenoid origin primarily inhabiting the eastern half of Southern Rhodesia north of the Lundi river (*see* BANTU LANGUAGES). Main Shona tribal groupings are the Zezuru, Karanga, Manyika, Tonga-Korekore and Ndau, the last three overlapping neighbouring territories. The leading tribe previous to European arrival was the Rozwi, associated with the Zimbabwe culture (*see* ZIMBABWE).

The Shona are farmers of millet and maize (corn), and occasionally hunt. Their cattle and other stock are important for marriage and ritual purposes. Their villages consist of clustered mud huts, granaries and common cattle corrals and accommodate one or more interrelated families, to a total of perhaps several score persons. Modern legislation is causing them to abandon the habit of shifting their village sites when the land is exhausted. Shona traditional culture, now fast declining, shows excellent ironwork, good pottery, but unimaginative basket, skin and woodwork. They are musically gifted, and their expert drumming and playing on the *mbira* (a flat hand instrument with curved, tuned iron bars), to accompany a rich variety of dances for old and young, are as much a part of ritual as of leisure time.

Shona personal and political relations are largely governed by a classificatory kinship system with exogamous clans (*mutupo*) and corporate patrilineages (*rudzi*). Chiefdom (*nyika*), ward (*dunhu*) and village (*musha*) are the territorial units, under hereditary leadership. Marriage is normally validated by *roworo* (cattle or cash) given by the groom in exchange for the bride. Polygyny and levirate (*qq.v.*) are allowed; but the position of women is fairly secure and they may hold and dispose of property in their own right.

Shona religious practices are concerned less with the creator-god Mwari than with the propitiation of ancestral, tribal and other minor spirits to ensure good health, rain and success in enterprise. Elementary European education, Christian missions and partial urbanization, while weakening traditional institutions and leadership, have barely affected the belief in magic, witchcraft and sorcery.

SHOOTING, as described in this article, is the sport of discharging firearms at targets as a test of marksmanship. Three basic types of firearm are used in this sport—rifles (including modern rifles, muzzle-loading rifles, and benchrest rifles), shotguns, and handguns (pistols and revolvers). (*See* GUNS, SPORTING AND TARGET.) Two of these are also the most commonly used hunting weapons—the modern rifle for shooting game animals and the shotgun for small game and wing shooting (shooting game birds in flight). The others are primarily target firearms, with the exception of some light benchrest rifles which are also used for shooting vermin (animals harmful to agriculture) at long ranges. For the sport of hunting with firearms and the shooting of game birds *see* HUNTING.

RIFLE SHOOTING

MODERN RIFLE

Firing Technique.—When mounted in shooting position a modern rifle is held with the heel of the stock (butt) forced firmly against the shooter's shoulder, which absorbs the recoil or "kick" of the weapon. When the weapon is fitted with iron sights, the

head is held low with the cheek pressed against the stock, so the eye can align the sights of the target; with telescopic sights, the head is necessarily held higher. Either shoulder can be used, but right-shoulder shooting is the most common. A few bolt-action rifles are made with the bolt handle, etc., on the left side for left-handed shooters who find it too awkward to operate the conventional kind. The right-handed shooter supports the fore-end of the rifle on the palm of his extended left hand with his left elbow usually directly below the barrel. It is this hand that directs the rifle in aiming it. At the same time the right hand grasps the grip, or "small," of the stock behind the trigger guard and pulls the rifle back against the shoulder while the tip joint of the forefinger is crooked around the trigger. The rifle is fired by squeezing the trigger rearward with a steadily increasing pressure, not by pulling or jerking it, since a sudden or violent motion can swing the sights from the target. To increase steadiness, the shooter holds his breath when firing.

The Shooting Eye.—The shooter's stronger (dominant) eye, his shooting eye, is used for best accuracy in sighting. To determine his shooting eye, the shooter holds the forefinger of one hand before him at arm's length and, with both eyes open, aligns its tip with a distant object. Then, without moving his finger, he closes his left eye. If his fingertip remains aligned with the object, his right eye is dominant and is his shooting eye. If his fingertip appears to shift from the object, he may have to use his left eye for sighting.

Positions.—Four specific body positions are used: offhand (erect), kneeling, sitting, and prone.

Offhand is the standing position common in hunting because it is the most quickly assumed and elevates the rifle above anything that might obstruct it in the other, lower positions. In the classic position, often modified, the shooter stands with his left side toward the target (when shooting from the right shoulder), his feet planted firmly about 18 in. (46 cm.) apart and his right foot to the rear, in line with his body and the target.

The kneeling position permits greater steadiness for shots at longer distances. The shooter sits on the side of his right foot or ankle with his right knee pointed at a 45° angle to the right of the target. His left elbow is rested on his left knee which is raised and pointed toward the target. Both this knee and elbow are directly below the rifle barrel and the body is inclined slightly forward for balance.

In the sitting position, which provides even steadier sighting, the shooter sits at an angle of about 45° to the target, his knees raised and his heels dug into the ground. His elbows or upper arms rest on his knees or slightly below them, with his left elbow and knee directly below the rifle barrel. In a variation of this position, the legs are crossed below the knees.

The prone position provides the steadiest sighting. To assume this position the shooter lies on his stomach with his body at a 45° angle to the target, both elbows resting on the ground with the left one directly below the barrel. The legs are spread wide apart with the toes turned outward and the ankles flat on the ground. This again is the classic position, which is greatly modified by many modern marksmen.

Muzzle-Loading Rifle

Although virtually obsolete since the American Civil War, the muzzle-loading rifle still has much romantic interest for many modern shooters. The American design for the "Kentucky," or long, rifle was developed in the 18th century by immigrant German and Swiss gunsmiths of Pennsylvania ("Kentucky" at that time being the name usually given to the largely uncharted hunting wilderness west and southwest of Pennsylvania). The Kentucky rifle has been credited with helping to win the American Revolution because its long-range accuracy was superior to that of the British "Brown Bess" smoothbore musket. Indeed, some British records of the war refer to the Kentucky rifle as an unethical secret weapon that could kill farther than the eye could see. Actually, its effective range was only about 300 yd. (274 m.) but this was nearly three times that of the Brown Bess. It was not used in large numbers by the Americans.

The muzzle-loader is held and fired like any rifle from the conventional positions, with one interesting addition in which the shooter lies on his back, resting on one elbow, and supports the barrel between his feet. This position (and numerous variations), made possible by the barrel's extreme length (40 in. [101.6 cm.] or more), came into vogue in the 19th century. The similar dimensions of the rifles used by some Oriental tribesmen, notably in the Pakistan-Afghanistan-Iran area, permit the barrel to be supported at about the point of the front sight between the shooter's toes. High accuracy results.

Benchrest Rifles

The benchrest rifle is fired in competition from a sandbag rest on a solid platform called a benchrest. These competitions are relatively new and largely confined to the United States, having been organized on a national basis with national competition in 1948. Participants are shooters who seek extreme accuracy, the ideal being a number of shots passing through the same hole in the target (*see* Guns, Sporting and Target: *Modern Target Firearms: Rifles*).

Shooting from a rest of one kind or another goes back at least to the late 18th century in colonial America. A later and highly organized phase occurred about 1840–90, chiefly in New England, using heavy percussion cap rifles, some weighing 30–40 lb.

SHOTGUN SHOOTING

Gun Handling.—The shotgun is mounted to the shoulder in somewhat the same manner as the rifle and is fired in the same way, the left hand (for right-handed shooters) supporting and directing the barrel and the right hand forcing the gun against the shoulder and squeezing the trigger. However, only the offhand body position is used since the shotgun is fired at flying targets (*see* Trapshooting and Skeet Shooting). (In the field, there are exceptions: sometimes single bullets called rifled slugs, instead of scatter shot, are used in the shotgun for hunting large animals such as deer, and the shotgun is sighted like a rifle; sometimes wildfowl are shot by sportsmen sitting or lying in boats.) Because the shotgun is pointed rather than sighted, it usually has only a single, bead-type front sight; but some shotguns also have a sight in the middle of the barrel. When a target flies in front of the shooter, he brings the gun to his shoulder as in the offhand position—though facing more toward the target than in rifle shooting—swings the gun's muzzle toward the target, and squeezes the trigger.

Swinging.—Proper swinging of the gun muzzle is a requisite for successful wing shooting since the charge of shot must be fired ahead of (lead) the flying clay pigeon to allow for the movement of the target, if it is to score a hit. One method is to swing the muzzle from behind the bird and through it to a position ahead of it, at which point the gun is fired. The swing is continued even beyond the point of firing with the follow-through motion in the direction in which the bird is flying. Moreover, a hit is more probable when the lead distance seems too great rather than too small because the shot pellets do not travel in a solid mass but form a long line called a shot string and, should the leading pellets pass ahead, those following them will probably hit the target.

Fit.—Another requirement for accurate shooting is proper fit of the shotgun. Since the gun must be mounted and fired quickly the shape and dimensions of its stock should be such that it can be mounted in perfect shooting position every time with no conscious adjustment of the shooter's body or head. When the gun is raised quickly into firing position, the shooter's cheek pressed against the stock, his eye should be looking directly down the top of the barrel in alignment with the front bead sight as he points the gun and swings on the target. To test his shotgun's fit, the shooter mounts the gun quickly with both eyes closed, then opens them. If his shooting eye is not in perfect alignment as described above, the gunstock should probably be altered.

HANDGUN SHOOTING

Stance.—The shooter's stance or body position is as important in handgun shooting as in other types but is not rigidly defined

and varies more with the individual. Each shooter can determine the one which suits him best by facing the target with his feet together and arms at his sides, moving the left foot outward from 12 to 15 in. (in the case of a right-handed shooter), raising the pistol to arm's length, and aiming at the target. If the arm feels strained, the left foot should be shifted backward until the strained feeling is eliminated. Once this most comfortable body angle is determined, it should be used at all times.

Grip.—The shooter's grip on the pistol (or revolver) may vary according to size of his palm and length of fingers. Sometimes the handgun must be fitted with a special stock, although this is uncommon except among competition shooters. In general, the stock should be cradled in the hollow between the thumb and fingers with the palm flat against the side of the stock, the thumb resting along the opposite side of the frame, and the remaining three fingers curled around the front of the stock under or behind the trigger guard. When the weapon is held correctly, the barrel, the wrist, and the forearm are in a direct line and the forefinger is in direct forward alignment with the trigger so that its only possible direction of motion is rearward. Only the tip joint of the forefinger should bend across the trigger. All fingers should exert firm and equal pressure on the weapon to hold it. The thumb, however, should exert no pressure in any direction. To keep the sights aligned on the target this equal finger-pressure must be maintained while the forefinger gradually squeezes the trigger rearward for firing. For accurate, consistent shooting the handgun must be held the same way each time and with the same pressure. The thumb is not used in handgun shooting except to cock the hammer of a revolver. In resting between shots during slow-fire shooting the handgun is lowered to rest the shooter's arm, but to maintain the grip for accuracy the positions of the fingers on the gun are not changed until an entire five-shot group has been fired.

COMPETITION

Competition with firearms is conducted on many levels, from the intramural matches held periodically by local shooting clubs or police forces to the Olympic Games, which draw the finest shooters from all over the world. Even the most stay-at-home shooter, through postal matches, can often engage in national and international competitions, firing at a local range and mailing his targets and scores to judges who compare them with results obtained by other shooters firing under similar conditions.

Although most shooting competitions are designed to test the marksmanship of the shooter, in some, such as the modern turkey shoot (usually a rifle contest based on a U.S. folk tradition) and in benchrest competition, the design or accuracy of the weapon may be an important, even decisive, factor. In other types of competition, accuracy may be secondary to some other point of judging. This section, however, deals primarily with formal competitions with rifles, pistols, and shotguns.

Rifle

Modern Rifle.—In the United States, rifle-shooting competitions are held throughout the year by various local (nonmilitary) shooting clubs and organizations under the sponsorship of the National Rifle Association of America (NRA) and by the branches of the armed services. The culmination of such competitions—to some extent they may be considered elimination trials—are the annual national matches, usually held during August, at Camp Perry, O. These events (which include handgun competitions) include the Small Arms Firing schools, the National Trophy matches, and the NRA championship matches. They are the responsibility of the secretary of the army and are under the supervision of the National Board for the Promotion of Rifle Practice (NBPRP). The NRA, which represents the great body of civilian shooters and whose championships are an integral part of the national matches, acts in an advisory capacity on policy matters and cooperates with the national match director and the NBPRP in scheduling and administering the matches. The rifle-shooting portion of the national matches includes competition with the small-bore rifle (.22 calibre) and high-power rifle (.30 calibre).

In the NRA championships, small-bore competition is divided into civilian, service (including both regular and reserve), and junior categories while high-power competition with service rifles includes civilian, regular service, and reserve categories. Competition with the high-power bolt (sporting) rifle is technically for civilians only, although military personnel may compete in this category.

The National Trophy rifle matches, conducted by the NBPRP, are fired with high-power service rifles. Competitors are divided into regular service, reserve, National Guard, ROTC (Reserve Officers' Training Corps), and civilian categories.

Each category in the national matches is further subdivided into various classes, based on previous performance, in order to equalize competition. There are awards for the highest scores in each class. Special awards also are made to ranking women, collegiate, senior (over 55 years of age), junior, and National Guard shooters. Rifle competition in the national matches is conducted at ranges varying from 50 to 100 yd. (45.72 to 91.44 m.; small-bore) or 200 to 1,000 yd. (182.88 to 914.4 m.; high-power). The type of sight and the shooting positions employed vary with the requirements and limitations of each match.

In Great Britain high-power rifle shooting and pistol shooting are organized and administered by the British National Rifle Association, founded in 1860. Similar to the U.S. national matches—with schools and competition for civilian and military shooters—is the annual Imperial meeting at Bisley Camp, Surrey, to which all countries of the Commonwealth may send competitors. The winner of the Queen's Prize, the chief individual award, wins not only a cup and honours but is traditionally seated in an armchair that is carried to the pavilion on the shoulders of his rivals.

Small-bore rifle programs in Great Britain are administered by county rifle associations and the National Small-Bore Rifle Association. Indoor ranges (15–25 yd. [13.72–22.86 m.]) or open ranges (up to 200 yd.) are used for competitions and there is an annual meet at Bisley.

In Scotland, at Barry, dedicated amateurs of professional skill fire at a range of 2,100 yd. (1,920.24 m.), hitting a 30-in. (76.2-cm.) bull's-eye. In this shooting the supine position (like that in 19th-century U.S. competition, and variously called "Texas," "Creedmoor," and "Fulton") is often used. Barrels of exceptional length (over 30 in.) are sometimes fitted to standard bolt-action rifles, and rear sights are placed on the heel of the stock rather than near the breech, to bring them closer to the shooting eye.

In other countries national shooting associations conduct special programs which may be colourful or of popular interest. In Sweden, "combat shoots" are a practical feature of paramilitary emphasis in the civilian rifle program. In this competition five-man teams, consisting of two riflemen, two submachine gunners, and an automatic rifleman, patrol through an area where they are unexpectedly confronted with silhouette targets showing enemy soldiers firing at the competitors. A "running dog" target also is used. Similar events are held with the shooters traveling on skis, as, for example, the biathlon in the winter Olympic Games (*see* Skiing).

In Switzerland the national shooting matches are held every four years, a different canton playing host each time. These shoots are noted for their pageantry and are well attended (over 50,000 at some shoots) because each male citizen, after completing military training, is given a military rifle with which he must pass annual qualifying competitions and inspections. In Italy the *carabinièri* conduct regular competitions with military arms.

Probably the largest shooting club in the world is the DOSAAF of the U.S.S.R. It is estimated that several million members have a basic familiarity with small-arms shooting, many of whom have qualified as "Voroshilov marksmen," skilled with rifle, pistol, and light machine gun. Soviet successes in Olympic and other international events are ascribed to their having so vast a training pool from which to draw. Rifle and other shooting sports are similarly encouraged in other Communist countries.

In the Federal Republic of Germany small-arms competition and training was de-emphasized after World War II, but com-

petitions are still carried on at ranges established by the *Sturmabteilung* (SA) between 1933 and 1945. Many of these ranges were taken over by units of the U.S. armed forces in the Association of American Rod and Gun Clubs in Europe, comprising about 100 clubs in Germany and about 30 more in other parts of Europe, with more than 30,000 members engaging in off-duty recreational shooting. Club charters were drawn up to admit German nationals to membership. Many club grounds formerly belonged to the old *Schützenbund,* for centuries social as well as sports groups in German life. Traditional German shooting events include running boar and deer, two quick shots at crossing targets at 100 m. Sometimes a poacher target is used, tracing back to the social upheavals of the Revolution of 1848; preserving the game and the hunting privileges was symbolic of stability in German society. In Austria, shooting sports follow the German *Schützenbund* system, with rules and regulations of the International Shooting Union observed in major competition.

Muzzle-Loading Rifles.—Current competition among muzzle-loading rifle shooters in the United States is a revival of the traditional American frontier sport of shooting at targets for prizes of money or food. The so-called Kentucky riflemen of early U.S. history and their feats of marksmanship with rifled muzzle-loaders are legendary. In exhibitions, one rifleman would shoot at a small board held between the knees of another at 60 yd. (54.86 m.). In the original version of the turkey shoot, a live turkey would be tied behind a rock some distance away, and competing riflemen would try to shoot off its projecting head.

The revival of target-shooting matches with these old firearms began in the 1920s. The National Muzzle Loading Rifle Association (NMLRA) was organized in 1937 and the sport has since grown steadily. Many of the rifles are originals, preserved by antique collectors or gathered from dusty attics and closets. Some have been reconditioned and the barrels of many have been relined with new rifling to restore their original accuracy. Flintlock-ignition types are rare and the majority are percussion-cap models. In competition either peep sights or open sights are used for the most part, the latter ordinarily being a square-post front sight with a square-notch rear sight. Some telescopic-sight matches also are held. Frequently sight shades are added to prevent glare from the sun.

Since the round lead ball fired by the muzzle-loader is ballistically poor, hence sensitive to crosswinds, large calibres from .45 to .55 are preferred in competition since their heavier weights have better crosswind resistance. Shooting matches test not only the accuracy of the individual rifle and the shooter's marksmanship but also his skill in loading the powder, patch, and ball and in judging the effect of the prevailing wind. Tournament competition includes open-sight matches at 50 and 100 yd., peep-sight matches at the same distances, and offhand matches at 25, 50, and 100 yd. Other competitions include matches in which the rifle is fired from a benchrest at 100 and 200 yd., muzzle-loading pistol matches, and shotgun matches.

The NMLRA conducts three large matches annually at Friendship, Ind.—a spring shoot, a fall shoot (national matches), and a turkey shoot in October. Competition is open to men, women, and junior shooters. Contestants frequently dress in old-style Kentucky rifleman costumes.

Benchrest Rifles.—The perfect target score in benchrest competition, with every bullet passing exactly through the same hole, may never be achieved because of certain uncontrollable factors such as wind drift and mirage. The latter, in this context, is a shimmering of the target image when seen through the rifle sights, caused by heat waves rising between eye and target or from the hot barrel. Many shooters, however, attain near-perfect scores in which all five bullets in a round pass almost exactly through the same hole in the target, with a spread as small as the cross section of a lead pencil. For this reason a paper strip, driven horizontally by a motor, moves slowly behind each target to prove that a complete round has been fired. Thus five shots may show on a target as a single ragged hole, but on the moving paper-backing they are strung out in a horizontal line.

In the United States two benchrest rifle championship matches are conducted annually under sponsorship of the National Bench Rest Shooters Association (NBRSA). In firing the national match course in the unrestricted category, any firearm may be used, even the most unconventional. This competition usually consists of ten 10-shot matches at 100 yd. and ten 10-shot matches at 200 yd., shot over several days. The aggregate of these matches determines the national match course grand aggregate winner. At these matches, shooters may also compete for separate awards with conventional rifles. The other national benchrest course (in the conventional rifle category), held separately, usually consists of five 5-shot groups at 100 and 200 yd. in each of three rifle classes—heavy varminter (total weight under 13.5 lb. [6.12 kg.]), light varminter (limited to 10.5 lb. [4.76 kg.] and a 16-power telescopic sight), and sporter (limited to 10.5 pounds and an 8-power telescopic sight). Championships are awarded the shooters with the smallest aggregate group size in each division.

Shotgun

Games.—Some current forms of shotgun-shooting competition in local U.S. clubs can be classified as games. One of these is the turkey shoot in which each competitor shoots at a small stationary square of cardboard at a specified distance. The shooter placing the most shot pellets in his card wins the turkey. This is really a test of the ability of the shotgun to fire a dense pattern of shot since such a pattern will normally score more hits than a sparse pattern. Similar games involve shooting at playing cards.

Clay Pigeons.—Since the shotgun is primarily a wing-shooting firearm, the most popular competition is shooting at targets in flight. These targets are circular disks of clay called clay pigeons because they have generally replaced the live pigeons which were formerly widely used in America and are still popular in parts of Europe and Latin America. Live-pigeon shoots, in which thousands of pen-reared birds were flighted and slaughtered in a single match, were curtailed in the U.S. and many other nations in the early 20th century because of the cruel and wasteful aspect of the sport. In the Principality of Monaco, live-pigeon shoots are a featured competition at the Casino Shooting Field, which is also the site of international skeet and trap clay-pigeon events.

Clay pigeons are usually thrown or scaled through the air to resemble flying birds, although in a variation of this method they are projected low across flat ground to simulate running rabbits and other small game animals which are also hunted with shotguns. The targets are propelled from "traps," named after the device from which the live pigeons were formerly released to be shot. These traps vary from simple hand-swung instruments to elaborate self-loading, electrically operated, and remotely controlled machines that can throw several clay pigeons at one time.

One type of clay-pigeon shoot is the grouse or quail walk, designed to simulate such bird shooting. The shooter walks along a woodland path and shoots both singles and doubles (two targets thrown at the same time) which are released unexpectedly from hidden traps.

In Great Britain, traditional tests chiefly governed by simulation of natural targets include driven partridge (shooter stationed behind opaque fence and targets are flung in pairs without warning from the other side), high pheasant (target flung in pairs from a 90-ft. [27.43-m.] tower), springing teal (targets flung vertically from hidden trap at ground level), running rabbit (target bowled along ground), and many others. However, trapshooting and skeet shooting are the most widely practised clay-pigeon sports, with both national and international competition.

For history and description of these sports *see* Trapshooting and Skeet Shooting.

Handgun

The sporting use of the handgun is largely confined to target shooting since this type of firearm has inherent disadvantages as a hunting weapon. Its relatively low-power ammunition limits its range and its short barrel limits its accuracy at longer ranges. Further, the relatively short distance between the front and rear sights (the sighting radius) makes it more difficult than a rifle to aim precisely. Some high-power (magnum) handguns equipped

with a telescopic sight, however, make fairly effective hunting weapons.

As with rifle shooting, the NRA National Pistol championships and the National Trophy Pistol matches, both part of the U.S. national matches at Camp Perry, are the culmination of local and regional competitions held throughout the year.

The NRA championships are conducted with all calibres of automatics (autoloading pistols), classified as .22-calibre, .45-calibre, and centre-fire (other calibres). Competitor categories are regular service, civilian, reserve, and police. These are further divided into classes and there are class and category awards as well as the national championship which goes to the shooter with the highest overall score.

The National Trophy matches, conducted by the NBPRP, are fired with the calibre-.45 pistol by competitors in regular service, reserve, National Guard, police, ROTC, and civilian categories.

Slow-fire pistol competition at the national matches is conducted at a range of 50 yd. Timed-fire (five shots in 20 sec.) and rapid-fire (five shots in 10 sec.) strings are fired at a range of 25 yd.

Muzzle-loading pistol matches, at 25 and 50 yd., are conducted by the National Muzzle Loading Rifle Association.

Police Shooting.—In almost every country where police are armed with handguns or, for special assignments, other weapons such as shotguns (riot guns) or submachine guns, training programs have been set up for the use of these weapons. As a result, many police officers compete in local, national, and international sporting matches, both open competition and matches for police only.

Police marksmanship training is divided, not always formally, into two categories. The first of these is normal target shooting at bull's-eye targets to sharpen marksmanship ability and familiarize the shooter with his weapon. Silhouette man targets are also used with the vital parts of the body outlined on them.

The second category, shooting at targets representing criminals, is often called "combat" or "practical" shooting. This is designed to test the officer's reflexes and ability to draw, aim, or point, and fire his weapon accurately under various conditions. In the United States practical shooting is conducted usually at ranges from 7 to 60 yd. (6.4 to 54.86 m.) and from various positions (standing, crouched, sitting, kneeling, or prone) with the shooter using either or both hands and firing in the open or from behind a barricade. In Sweden a "running thief" target is used. Hits on this target above the legs count against the shooter as it is his job to capture a criminal, not kill him. In other variations used in the U.S., motion pictures of running men are fired upon or surprise pop-up targets appear singly or in groups as the shooter moves along a firing line. In this latter form of training the shooter may be penalized if he fires upon a target representing an unarmed man or an armed man using another person as a shield. Further, in the case of more than one target, the shooter must decide almost instantaneously which should be fired upon first, *e.g.*, one representing a criminal with a drawn and aimed gun as opposed to another in the group showing a criminal who is just drawing his gun.

In this type of shooting, often called "instinct" shooting, there is little or no time for aiming. Instead, the shooter simply points the gun at the target and fires. Practice can lead to a high degree of accuracy in this type of shooting.

International

The heritage of international rifle shooting is strongly Germanic, hence the weapons used, particularly in the "free" categories have some semblance to traditional German target arms. For the offhand position deeply curved butt plates with long underarm hooks or prongs are fitted to muzzle-heavy rifles. Trigger pulls adjustable down to a few ounces are permitted and some rifles have miniature roller sunshades which fasten near the front sight and can be pulled back to the breech. Nonreflective webbing or fabric is placed over the barrel to break up heat waves and avoid "mirage." (*See* also Guns, Sporting and Target: *Modern Target Firearms: Free or Unrestricted Firearms.*)

World Championships.—The world championship shooting matches are held in a different country each year under the auspices of the International Shooting Union (ISU), which was founded in 1907 and reorganized after World War I. Competitions are with the small-bore rifle, free rifle, centre-fire pistol, free pistol, rapid-fire pistol (.22-calibre), and shotgun. The army rifle match and the national match are fired with a military weapon designated by the ISU.

The small-bore rifle competition consists of firing from three positions (standing, prone, kneeling) at a range of 50 m. Three-position matches are held at 300 m. in the free-rifle (unrestricted as to rifle design and accessories) and army-rifle competitions.

Free-pistol matches are conducted at 50 m. while centre-fire and rapid-fire competition is at 25 m.

Running-deer competition is conducted at 100 m. with the shooters firing at rapidly moving silhouette targets. Clay-pigeon (trapshooting) and skeet matches are also conducted.

NATO.—Among the nations of the North Atlantic Treaty Organization an annual military shoot is conducted during the summer. Although the competitors are full-time military personnel on duty assignment the program of the Prix Leclerc, as the matches are called, has taken on the characteristics of a sporting event. Special matches for light-machine-gun and submachine-gun shooters, however, leave no doubt that this is basically a military exercise.

Olympic Games.—Shooting has been a recognized Olympic sport since the first modern Olympic Games in 1896. In addition to the more regular events of shooting competition, however, Olympic shooters have also taken part in such events as live-pigeon shooting and competition with dueling pistols. In the winter Olympic Games the biathlon is a combination of cross-country skiing and rifle shooting. *See* Olympic Games.

AIDS TO ACCURACY

With hunting activity being limited by shorter seasons and diminishing game populations, target competition among modern hunting-rifle shooters has shown a rapid increase. This has stimulated attempts to obtain a degree of accuracy from both firearms and ammunition far beyond that needed in hunting. One result has been an increased production of extremely precise sighting equipment and accessories which the shooter can add to his basic rifle to increase his accuracy. Another result has been a growing interest in handloading, the refilling of fired rifle-handgun cases with more exact weights of powder and bullet than are obtainable in some production-line ammunition, in order to obtain the consistent ballistic performance needed for near-perfect accuracy. An increasing number of shotgunners are also handloading their fired shotshells, but the principal reason is economy rather than precision since empty shells can be reloaded for less than half the cost of new ammunition.

Shooting Accessories.—Since rifles are usually delivered from the factory with a minimum of equipment, shooters often install accessories to help them handle the weapon more efficiently and shoot more accurately. Factory-installed open rear sights are simple and cheap but optically inefficient. In most cases they are difficult to adjust precisely for windage (lateral adjustment to compensate for the wind) or for elevation (vertical adjustment for different distances) and are usually replaced by adjustable peep sights or telescopic sights. The peep sight is preferred over the telescope for shooting animals, especially running animals, at distances up to 100 yd. because it provides a wider field of vision. The telescopic sight is better adapted to long-range shooting at both stationary animals and targets. Since shotgun sights are not as critical, they are less frequently replaced. For more accurate handgun shooting an adjustable rear sight is frequently added; and many handguns are factory equipped with such sights.

For shooting with a rifle, an adjustable leather or web sling is often used. One end is fastened to the rifle's fore-end, the other to the stock. By looping the sling tightly above the elbow of his aiming arm, the shooter can steady the gun for more accurate sighting. In both shotguns and high-power rifles a rubber recoil pad, fitted to the butt of the stock, protects the shooter's shoulder from excessive recoil and helps prevent flinch, an involuntary reaction at the moment of firing which pulls the sights

from the target. Earplugs can also help prevent flinch. For single-barrel shotguns, variable choking devices which fit over the muzzle are often used to vary the spread of shot pellets. Gas vents in some of these devices also help to reduce recoil. In match handguns, special accessory triggers and fitted handgrips are used. Some factory-supplied grips are replaced by grips of carved ivory or exotic woods. A common accessory for target shooters is the spotting scope, a powerful, tripod-mounted telescope (up to 40 power) used for determining the positions of bullet holes in targets at long ranges.

Handloading.—The reloading of fired centre-fire brass cartridge cases by hand (rimfire cartridges are seldom reloaded) and of fired shotgun shells increased in popularity after 1950 with the availability of efficient and inexpensive hand-operated reloading tools, called presses. In cartridge reloading for both rifle and handgun the press ejects the fired primer from the empty case and simultaneously forces the case into a resizing die to restore the stretched brass to its original shape and to adjust the case mouth to receive the bullet. Another device on the tool inserts the new primer. Then the shooter measures or weighs the correct amount of powder necessary, determined from a chart, and fills each primed case. Finally the press inserts the bullet in the case neck. A shotgun-shell reloading press operates similarly: depriming, resizing, and repriming. Then the powder is added and the gas-sealing wads, forced against the powder at a predetermined pressure by the press, are inserted. Next a measuring device on the press meters the desired weight of shot into the shell and another device applies the final crimp to seal it.

Handloading is safe when simple rules are followed. Smoking is prohibited during the process. All cases or shells to be reloaded must be in good condition. Primers must be handled carefully since they can be detonated by a sharp blow. Special care must be exercised to use only the exact amounts of the powders recommended by the chart which accompanies all reloading handbooks. Maximum powder loads should be used with caution.

SAFETY

Statistically, a shooter has a greater chance of being injured accidentally by a fall in a bathtub than he has by a gun while out hunting or shooting, but to decrease the number of firearm accidents that do occur, certain safety rules are recommended. Every firearm, even when apparently empty, should be treated as though it were loaded. Even an apparently empty firearm should never be pointed at anything the bearer does not intend to shoot at. Only empty disassembled firearms should be carried in a car, or kept in the home or in a hunting camp. On the range or in the field, the firearm must be carried so that the shooter can always control the direction of its muzzle, even should he stumble, and its "safety," a device which prevents the firing mechanism from operating, should be in the "on" position. It should be remembered, however, that with very few exceptions standard-design safety systems lock the triggers only, and not the sear (the catch that holds the hammer at cock or half cock). Before firing, it must be ascertained that the barrel is free from obstructions such as snow or mud or a forgotten cleaning patch. With a rifle or handgun, shooting into the air should be avoided because such shots endanger distant people, livestock, or buildings. Even with low-power cartridges, shooting at hard flat surfaces, or at water, is dangerous because ricocheting bullets can travel long distances. Before any shot with a rifle or handgun, the shooter should make certain the backstop (dense trees, a hill, etc.) will stop his bullet should it miss the target aimed at. The drinking of intoxicating beverages or the use of any drug, which might dull the shooter's judgment and caution, can be dangerous. In the U.S., many states require new hunters to take National Rifle Association training and safety courses before a hunting licence will be issued.

(G. H. P.; W. B. Ed.; W. S.)

SHOOTING STAR (American Cowslip), a plant of the genus *Dodecatheon* of the primrose family (Primulaceae), comprising species native to North America and northeastern Asia. They are stemless, perennial herbs, with basal leaves and a naked flower stalk, which bears at its summit a cluster (umbel) of singularly shaped flowers similar to those of the garden cyclamen (*q.v.*). The shooting star commonly grown in gardens, *D. meadia*, with pink or white flowers, is native in open grounds in eastern North America. Throughout the Middle West the native *D. meadia* is sometimes called prairie pointer because of its pointed and apparently inverted flower, which blooms in late April or early May. Numerous species occur in the western states, seven being found in California, among which are the Sierra shooting star (*D. jeffreyi*), the lowland shooting star (*D. patulum*), the upland shooting star (*D. hendersoni*), often called mosquito bills or sailor caps, and *D. clevelandi*, with handsome purple and yellow-spotted flowers. All are cultivated for ornament, but western species do not grow well in eastern gardens. Shooting stars do best in wild flower gardens partially shaded and in well-drained soil. (N. Tr.)

SHOP FRONT DESIGN. The purpose of a shop front is to identify the name, character and nature of the store or shop, and, usually, to give a full or token display of the goods or services offered inside. Of the many devices and techniques employed by the merchant to attract the attention of customers, two of the commonest are a sign or some graphic identification of the store name, and a show window or windows.

Before the concept of a specialized store architecture evolved, merchants occupied space in such buildings as were available; a sign was added to the building or store front and the owner did what he could to enlarge and give importance to existing show window space. Later, as modern retailing developed, stores occupying old buildings broke out the street wall and created new fronts to gain greater display space, provide surfaces for large building front signs and enlarge their entrances. These practices continue wherever it is not practical or desirable to erect a new building. In modern buildings utilizing steel framing and non-load-bearing walls, store architecture is offered the potential of a completely transparent main floor selling area and maximum shop front display.

Signs.—Some of the commonest types of signs are raised lettering backlighted against the store façade; neon lights; letters applied on a luminous glass lintel; and bronze or metal letters applied to the face of the building. Usually a clear script or block lettering is utilized and the sign is executed as an architectural element of the store front.

In modern retailing techniques a store's sign serves as its trademark, used in all its advertising and in its packages, labels, letterheads, truck panels, etc. Before the development of local and national advertising, the sign was often required to describe the store. It was then not so much a trademark as an informative poster, and the store's name was often presented on the sign in conjunction with such descriptive phrases as "dry goods store," "ladies clothing and furnishing goods," etc. Later, as advertising made the name synonymous with the services and goods offered, the use of such phrases went out of fashion.

Windows.—Store fronts can be classified on the basis of the types of show window they employ: (1) a conventional show window or windows spaced out across the face of the building; (2) unit displays set within the store behind a total glass front interrupting but not obscuring the view of the interior of the store; and (3) continuous glass which exposes the main floor interior completely. Display methods relate directly to the way a store conducts its business. Supermarkets and some chain stores, for instance, have found that the all-glass front best serves merchandising based on offering a great mass of goods at low cost. Thus, the store itself is the display. Specialty shops, on the other hand, prefer to use key displays set behind an open glass front, presenting samplings of the total merchandise.

Size also may affect the appearance of a specialty shop front. Seldom occupying the space of a chain store or supermarket, such a shop must use some of its interior space to increase the perimeter of the show window from the street. Thus a great many shop fronts are recessed into arcades cutting into the interior store space. The effect on the appearance of the shop front is one of a

diagonally placed show window which can be seen as the shopper approaches the store along the street. The arcade, further, offers a place for window-shopping under shelter. Many shops of this kind have ceiling lighting patterns which start in the ceiling of the arcade and continue into the store proper.

Major department stores still make profitable use of the show window framed in the building wall, which serves to intensify the appeal of selected items. Window displays are changed as often as the store's promotional needs require and are designed by display specialists. Every theatrical device is employed: special sets, lighting, background treatments, properties, etc. (*See* also DISPLAY DESIGN.)

Modern Developments in the United States.—Among considerations affecting the design of store fronts in the United States, modern structural techniques and materials are of the foremost importance. But second only to these is the location of the store, particularly as it is influenced by increased use of the automobile. Special mention may be made of the shopping centre and multiple-unit retail operations—branch stores and chain stores.

Shopping Centres.—In city locations buildings occupied by stores may vary in size, height, age, style of architecture and materials; and a venerable brick building adjoining a new porcelain enamel shop front render each other distinctive by contrast. In the shopping centre, stores conform generally to the modular character of the centre, and the problem of achieving individuality rests chiefly on window display and signs. The total centre has a character, in effect that of a shop front; a major sign, dramatically lighted, usually identifies the unit as a whole. The sheer intensity of the light attracts and, as customers come close to the centre, makes all high-placed signs legible. The all-glass open front is associated primarily with supermarket design; variations in treatment must be effected so that two or more supermarkets occupying the same shopping centre and using the same display technique can be distinguished from each other.

Multiple-Unit Operations.—Branch stores are generally housed in one- or two-story buildings with customer approaches from one of several parking lots, and all the faces of such stores bear a part of the burden of identification and display. Usually removed from a steady stream of pedestrian traffic, the store cannot hope to attract customers primarily with enticing street window displays, and the show window thus diminishes in importance. The store generally makes its initial impression on a customer arriving by automobile, and the entire building may thus serve as a signboard. Signs are enlarged, placed high and lighted so that they can be seen from a considerable distance. A downtown store usually depends on one or two major entrances, seldom more; a branch store may have as many as there are approaches from parking lots. Since many branch stores are located in residential communities in which the land has never been leveled for commercial use, store designers are capitalizing on sloping or variable sites, often utilizing lower- and upper-level entrances. The architectural treatment usually reflects the prevailing domestic architecture of the community, and the exterior treatment is much less flamboyant than it would be on a city shopping street. Neon or other spectacular sign treatments are seldom used, or needed, because of the store's isolation from competing shops.

Chain stores use prototypes for signs and in some instances for building design. Among notable successes in achieving a distinctive character in sign, architecture and shop front are the Howard Johnson chain, which houses its restaurants in pitched roof, gable, quasi-colonial buildings with a white, coral and turquoise colour scheme; and Shell gas stations, with their strong, formalized shell trademark and startling colour combination of yellow and orange. (W. SN.)

Modern Developments in Europe.—The rise in living standards and the change in shopping habits after World War II have contributed to a complete overhaul of store design and, in particular, the display planning of the shop front. The open front has become the accepted formula except in a few cases of stores of an exclusive nature, *e.g.*, a jeweler, and even here the all-glass or toughened plate glass door, gives some visibility of the interior.

The most important development in postwar Europe has been the "doorless" entrance or air curtain doorway; the earliest examples were used in the Globus store at Basel and the Jelmoli store at Zürich in the early 1950s. The doorway has a lobby with a low, louvred ceiling and a closely divided metal grid for a floor; warm air passes through the ceiling and is extracted through the floor, creating a warm air curtain which retains the heat of the interior without impeding entrance into the shop. The entrance is closed at night by a sliding or rising wall which may be a glass screen, can incorporate doors, or may even be a display window or showcase. Later examples effected a compromise by a system of toughened plate glass swing-doors which operate during adverse weather conditions but will fold away, concertina-wise, giving an unobstructed entrance. In the late 1950s France and Germany introduced the use of adhesive and "clip" joints in the glass, eliminating even metal frames and surrounds, and increasing visibility. A development of this system around 1960 led to "suspended" glazing where huge sheets of plate glass were hung by metal clips from a structural member (instead of being bedded in frames). This, combined with adhesive joints, allowed the glazing of immense areas—often the whole frontage of a large store—without any interruption of visibility.

Self-service and self-selection, which help to turn the "window-shopper" into a customer, have played their part in encouraging the open front and unobstructed entrance. The open front has raised new design problems such as reflection, sun glare and sun control, artificial lighting by both day and night, a general reorganization of merchandise within the store, now completely exposed, together with a new approach to the design of display fixtures and fittings. Freer handling of levels within the shop makes it possible to expose more than one floor of the interior to the street. Many split-level shops exist in Germany and the idea was developing rapidly in Europe in the 1950s and 1960s.

Another important factor is the imaginative use of colour and lighting. Cleverly used, colour can enhance the merchandise on display. It can also modify undesirable architectural features which cannot otherwise be corrected; for instance, disguising the length of the long narrow store. Different harmonizing or blending colours also identify and separate adjacent displays, and relate them, by the use of similar colours, to the departments within the store. Lighting has become an integral part of design. Intensities are five or six times greater than prewar lights, but because this is common to all shops, a degree of lighting monotony has been created. Effective lighting therefore needs contrast, perspective and colour as well as brightness. To bring out correct colour values, a combination of fluorescent and incandescent fixtures is common, as each stresses a different end of the colour spectrum. Much recent progress has been made in the use of the low voltage spot lighting which can focus beams of great intensity on particular items thus punctuating and dramatizing the display even against the greatly increased general brightness. The fittings incorporating the low voltage lamps are very small and unobtrusive, and are placed in the windows at points to give the greatest effect. (*See* also LIGHTING: *Electroluminescence: Retail-Shop Lighting.*)

Design and layout of lettering on signs had improved by the 1960s, and the increased use of plastic coverings, particularly in England, was eliminating the naked neon tube type of sign, although the latter still predominated on the European continent. (E. So.)

SHORE, JANE (d. 1527), mistress of the English king Edward IV, is said to have been the only child of Thomas Wainstead, a prosperous London mercer. She was married at an early age to William Shore, a goldsmith, and became mistress to the king *c.* 1470. Although she wielded great influence over the king, Sir Thomas More (*Richard III*) asserted that his favour "she never abused to any man's hurt, but to many a man's comfort and relief." After Edward's death (1483) she was mistress of Thomas Grey, 1st marquess of Dorset, son of Queen Elizabeth Woodville by her first marriage, and she was also a concubine of Lord Hastings. She probably acted as an intermediary between the Woodville party and Hastings in opposition to Richard, duke of Gloucester, and therefore incurred the latter's hostility. In

June 1483 Richard (who became King Richard III later that month) accused her of sorcery, had her arrested, and afterward got the bishop of London's court to make her do public penance as a harlot; but all the beholders pitied her for her great beauty and patience. Her husband was now dead and she was imprisoned in Ludgate. There she captivated the king's solicitor, Thomas Lynom, who wished to marry her. Richard dissuaded him and Jane's fortunes never recovered. She died as a beggar in 1527.

See Sir Thomas More, *History of King Richard III,* ed. by J. R. Lumby (1883). (A. R. M.)

SHOREHAM-BY-SEA, a seaside resort and urban district in the Arundel and Shoreham parliamentary division of West Sussex, Eng., 6 mi. W. of Brighton. Pop. (1961) 17,410. Area 4.8 sq.mi. It lies at the mouth of the Adur river and 1 mi. upstream is the village of Old Shoreham, the original port, whose importance declined with the eastward shift of the river mouth, now 1 mi. from New Shoreham. The modern harbour embraces this lower reach of the river and also a semiartificial waterway that extends eastward from the river mouth for 2 mi. to Portslade and where ships can lie afloat at all states of the tide.

Shoreham was called a borough in 1236 and from 1272 to 1885 returned two members to parliament. Weekly markets and an annual fair dating from the time of Edward I were held for centuries. Shipbuilding has been carried on since the 13th century, and there is trade in coal, grain, timber and cement.

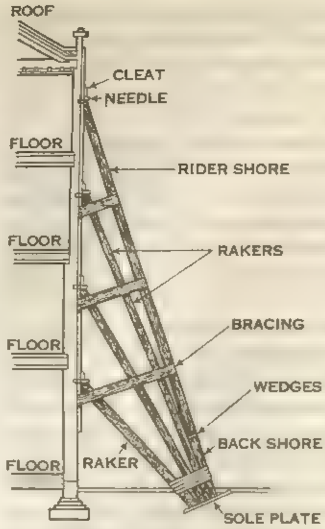
On the west side of the Adur opposite Shoreham is the Brighton-Worthing municipal airport; to the northwest of it is Lancing college, a public school for boys. At Shoreham Gap, 2 mi. N.E., 596 ac. of downland were presented to the National trust in 1946.

SHOREY, PAUL (1857–1934), outstanding U.S. classical scholar and humanist, was born at Davenport, Ia., on Aug. 3, 1857. Having graduated from Harvard in 1878 he was admitted to the Chicago bar in 1880. Later he studied at Leipzig, Ger. (1881–82), Bonn, Ger. (1882), the American School of Classical Studies at Athens (1882–83) and the University of Munich, from which he received the Ph.D. in 1884. He was professor of Greek at Bryn Mawr college (1885–92), then went to The University of Chicago as professor of Greek and chairman of the department of Greek. He was Roosevelt professor in the University of Berlin, 1913–14. A man of vast erudition, Shorey was a brilliant teacher and lecturer, especially in the fields of Greek poetry and philosophy.

Shorey's writings include *The Idea of Good in Plato's Republic* (1895); *The Odes and Epodes of Horace* (1898); *The Unity of Plato's Thought* (1903), his most significant work in that it summed up his whole concept of Plato; *The Assault on Humanism* (1917); *What Plato Said* (1933); and his edition (with English translation) of Plato's *Republic* (Loeb Classical Library, 1930–35). He was a constant contributor to *Classical Philology*, of which he was managing editor from 1908 until his death in Chicago on April 24, 1934. (G. Sm.)

SHORING, a form of prop or support, generally temporary in nature, used during repair or original construction of buildings, and in excavations. Temporary support may be required, for example, to relieve the load on a masonry wall while it is repaired or reinforced. The support may be supplied by shoring the wall with heavy timbers sloping upward at about 60°–75°. The top of the timber is so arranged that part of the wall load will be transferred to the shore. The lower end of the shore will frame onto a base in order to transfer the load to the ground with a minimum of deformation. Wedges may be used to bring the shore snuggly into contact with the wall. If the wall is several stories high, as in the figure, more than one shore is required. The spacing between the shores depends upon the condition of the wall, magnitude of the load, structural quality of the shores, and the character of supporting base and ground.

Shores are used to support the forms for cast-in-place concrete slabs, beams and girders in reinforced concrete frames. Such supports may be 4 × 4's or larger timbers cut to appropriate length and placed to true grade by wedges. The size of the timber depends upon the load and length of the shore. Lateral bracing is needed in both directions to prevent the buckling of



SYSTEM OF RAKING SHORES

the shore. In some cases timbers may be framed into towerlike arrangements to provide capacity for greater loads. There are several patented shores that may be used in place of timber shores for concrete forms. These have the great advantage of easier placement and easier adjustment for length. The adjustment may be made by means of a threaded member or by a gripping device.

One method of constructing a pier in water is to use a cofferdam, which may be a rectangular enclosure made by driving sheet piling, usually steel, around a horizontal frame system. The outside members of the frame against which the sheet piles bear are called wales. The transverse and longitudinal members between the wales are shores. The wales and shores may be constructed of heavy timbers, structural steel, or a combination of the two materials.

The shores must be sturdy and well braced to withstand the shock of being hit by a heavy dredging bucket; they must also be able to withstand the horizontal forces resulting when the water is pumped from the cofferdam. The number of horizontal frames required may vary from one to five. (F. W. St.)

SHORT, SIR FRANK (Francis Job) (1857–1945), English topographical engraver and water-colourist, was born at Wollaston, Worcestershire, on June 19, 1857. He was educated to be a civil engineer, and in 1881 came to London. In 1883 he studied at the Royal College of Art, the Westminster School of Art and the Royal Institute of Painters in Water-Colours. Short's style was at first closely modeled on that of Seymour Hayden's, and earlier successes included mezzotints after J. M. W. Turner's *Liber Studiorum* (1885 *seq.*) and his best original works are mezzotints and aquatints such as "The Night Picket at Hammersmith" (1916) and "Morning Flare in Chichester Harbour" (1922). Elected A.R.A. in 1906, he was knighted and made a royal academician in 1911. As director of engraving at the Royal College of Art (1891–1924), he greatly influenced younger engravers. He published *On The Making of Etchings* (1888). He was president of the Royal Society of Painter-Etchers and Engravers (1910–38). He died April 22, 1945, at Ditchling, Sussex. (D. L. Fr.)

SHORTHAND is any system of rapid writing using symbols or shortcuts that can be made quickly to represent letters of the alphabet, words, or phrases. It has been variously known as stenography (close, little, or narrow writing), tachygraphy (swift writing), or brachygraphy (short writing). Shorthand is now employed extensively in reporting the proceedings of legislative bodies, the trial of cases in courts of law, and for taking dictated business correspondence.

The earliest record of an organized system of shorthand dates from the year 63 B.C., the age of eloquence in Rome. At that time Marcus Tullius Tiro, a freedman and friend of Cicero, invented a system of *notae* that was used in recording the speeches of Cicero, Seneca, and others of the Roman Senate. The system invented by Tiro was taught in the Roman schools, was learned by emperors, and was widely used. In his life of Cato the Younger, Plutarch stated that the speeches of Caesar and Cato in connection with the conspiracy of Catiline were taken down verbatim by *notarii* who had been placed by Cicero in various parts of the Senate. After the fall of the Roman Empire the use of the Tironian system survived for several centuries.

Beginnings of Modern Shorthand.—England was the birthplace of modern shorthand. The publication by Dr. Timothy Bright in 1588 of his *Characterie: an Arte of Shorte, Swifte, and Secrete Writing by Character* marked the beginning of this development there. In the next 50 years, thirteen systems were

known to have been published, a number of them passing through several editions. They were orthographic, *i.e.*, they followed normal spelling, although many omitted silent letters. One of the best known of these early systems was Thomas Shelton's *Short Writing* (1626), in which Samuel Pepys kept his famous diary. Nearly two centuries later another famous English author, Charles Dickens, learned shorthand and earned his living for a time as a reporter in the law courts and in Parliament.

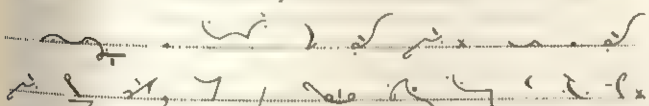
Although most of the early systems of shorthand in England were orthographic or alphabetic, the idea of writing according to sound continued to gain in favour. The Rev. Phillip Gibbs (1736) was the first to break away from an alphabetic basis to a phonetic one by distinguishing between long and short vowels.

Pitman System.—The publication by Isaac Pitman in 1837 of *Stenographic Sound Hand* marked a new era in the development of phonetic systems. Not only did he classify the sounds of the language scientifically and arrange his material for writing accordingly but he also introduced simple expedients of abbreviation that made for rapidity. A short summary of the principles underlying the system is given.

Since the system is phonetic, all words are written according to their sounds. The words *lain, deal, may, knife* would therefore be written as if they were spelled *lān, dēl, mā, nīf.* The consonants are drawn from simple geometrical forms, straight lines, and shallow curves. As far as possible all consonants are paired: a lightly written stroke represents the sound of F, for example, and the same stroke, written slightly heavier, stands for the companion heavy sound of V. To illustrate: P ... B ... T ... D ... Vowels are indicated by disjoined dots and dashes, which are placed in proper relation to the consonants and by writing words in position with relation to the line of writing. To illustrate: bay ... tea ... ode ... bug ...

The Pitman system makes use of circles, loops, and hooks for sounds of frequently used consonant combinations and syllables (*i.e.*, S, ST, STR, SPR, -ter, -der, -tion, etc.). Syllables are also added by halving or doubling the length of a consonant stroke.

Illustration of Pitman Shorthand



Many years ago the family was the social unit. Now the social unit has become the world, in which each person's welfare affects that of every other.

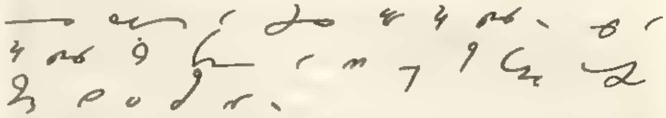
The Pitman system was introduced into the United States a few years after its publication. In the Eastern Hemisphere, including Australia, New Zealand, and India, Pitman is the predominant system of shorthand; more than 250,000 people in these areas learn Pitman every year.

Just as Pitman and some of his contemporaries rejected the orthographic principle in shorthand and adopted the phonetic basis, another group of authors discarded the use of geometrical signs in favour of cursive symbols. As early as 1620 William Folkingham produced *Brachygraphie Post-Writt* in which he anticipated Gregg and the more modern "script" systems and used blended consonant signs for such combinations as FL, FR, TR, etc. He also introduced position writing to indicate vowels.

Gregg System.—In 1888 John Robert Gregg published his *Light-Line Phonography* in England and soon thereafter brought his system to the United States. It is taught in more schools and practised by more stenographers in the United States than any other system. It is published and taught in most of the nations of the world.

The Gregg system is based on the following principles: (1) The system is phonetic; all words are written by sound. (2) There is a total absence of shading or thickening; all symbols are written light-line. To illustrate: r l t d n m . (3) The characters are based on the elements of ordinary longhand; the strokes are familiar and the motion is uniform. (4) Vowels are expressed by circles and hooks; the words are not placed on, above, or through the line of writing to imply the omission of certain vowels. To illustrate: a e o u . (5) Vowels are inserted in word outlines in their natural order without lifting the pen. To illustrate: reel late den name . (6) There is a preponderance of curve motion to aid writing. The Gregg system makes use of brief forms for some of the commonest words, blended consonants, suffix and prefix forms, and an abbreviation principle in order to enable the writer to gain speed in writing.

Illustration of Gregg Shorthand



Many years ago the family was the social unit. Now the social unit has become the world, in which each person's welfare affects that of every other.

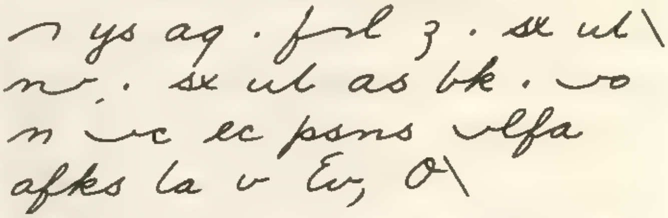
Longhand Shorthand Systems.—A recent trend in the development of shorthand systems makes use of longhand symbols for most, if not all, of the letters of the alphabet. Illustrations are: Abbreviatrix (1945), Baine's Typed Shorthand (1917), Carter Briefhand (1957), Forkner Alphabet (1955), Gersten's Alphabet Shorthand (1949), HySpeed Longhand (1932), Quickhand (1953), Speedhand (1952), "Speedwriting" (1923 and 1951), Stenoscript (1955), Stenospeed (1953), and Zinman (1950).

The first "longhand shorthand" is found in *Cadmus Britannicus* by Simon George Bordley (1787), which comprised three systems. The first, called "Slower Shorthand," used letters of the alphabet; the second, "Swifter Shorthand," was a script shorthand; and the third was "Shorthand for Music." The main difference between Bordley's "Slower Shorthand" and modern systems of this type is that Bordley's letters were "printed" longhand and could not be joined.

The advantages claimed for alphabetic systems are ease of learning because of the learner's familiarity with the forms, a shorter learning period than is needed with symbol systems, and the ease of transcription. The chief disadvantage is limited speed.

The system known by the registered trademark "Speedwriting" was devised by Emma Dearborn in 1923. It is written by sound; only long vowel sounds are expressed. To illustrate: knew *nu* bill *bl* file *fl* did *dd*. Some letters are modified for speed. To illustrate: t (crossmark omitted), i (dot omitted), m, w (humps omitted).

Illustration of "Speedwriting" Shorthand



Many years ago the family was the social unit. Now the social unit has become the world, in which each person's welfare affects that of every other.

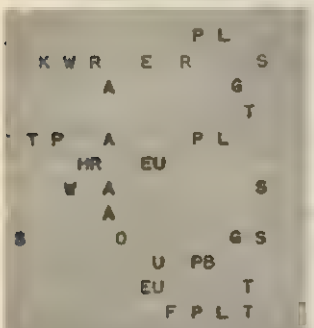
In addition, brief forms, phrasing, abbreviating principles, and flourishes are used. A few of the flourishes follow: (1) a line drawn under the final letter expresses final *ing* and *thing:* billing

, nothing ; (2) the *f*, extended upward, expresses *ification:* verification ; (3) the *s*, extended upward, *self, selves:* myself , ourselves .

In Britain there has been a steadily increasing following in recent years for *Speedhand* by C. T. Rutherford (1952). It is a system that can be used either by hand or on the typewriter, and it is claimed that it can be learned in 15 hours.

Machine Shorthand.—Machine shorthand is the method of recording speech by the use of machines, a method developed in the last quarter of the 19th century. The Stenotype and Stenograph shorthand machines are common examples. These two machines have identical keyboards of 22 keys. All fingers and thumbs are used; any number of keys can be struck simultaneously; a strip of folded paper moves ahead with each stroke, carrying the imprint of as many keys as were struck.

Illustration of Stenograph Machine Shorthand



Many years ago the family was the social unit. Now the social unit has become the world, in which each person's welfare affects that of every other.

Each key prints a letter of the English alphabet (except one which prints an asterisk). The basic principle is the recording of a syllable at a stroke, phonetically. The fingers of the left hand control keys that print consonants occurring before vowels; these print at the left side of the tape. The thumbs control vowel keys, which print in the middle of the tape. Fingers of the right hand control consonants occurring after vowels and print at the right. Thus most consonants can be written on either side of the keyboard.

Letters for which there are no keys are represented by combinations of other letters. Arrangement of the consonants on both sides corresponds with the sequence of sounds as they occur in the English language. Abbreviated forms are used for some of the most frequent words, enabling the operator many times to write two or three words in one stroke. Completed notes are in the form of a folded pad.

Advantages claimed for machine shorthand over manual systems are greater speed and the interchangeability of the notes. Disadvantages reported are inconvenience (machine instead of pen) and difficulty of revising notes already taken.

Two machines that have been in use in Europe are the Grandjean (France) and the Palantype (Britain). The latter takes notes in phonetic print rather than by means of a "code" and the majority of words are instantly recognizable to anyone who has never operated a machine, provided the keys are depressed correctly.

Shorthand in Other Languages.—Soon after pen shorthand was introduced in England, other systems appeared on the continent of Europe. The first French system was Jacques Cossard's *Méthode pour escrire aussie vite qu'on parle* (1651). Coulon de Thévenot published his *Tachygraphie* in 1787, and in 1826 a system was invented by Hippolyte Prévost; this system was improved by Albert Delauney in 1878. Today it is known as the Prévost-Delauney system and is one of the two most widely used among French-speaking peoples, the other being that of Abbé Duployé (1862). They are based on geometric principles with joined circles, hooks, and loops for the vowel sounds. In Germany the most notable systems have been those of Franz Xavier Gabelsberger (1834) and H. Wilhelm Stolze (1841). In Italy the adaptation of Gabelsberger by Noë, subsequently altered by various authors, is widely used. There is hardly any language in the world that has not had its own shorthand system at some time or other, including Eskimo and American Indian languages.

(S. J. Wa.; E. H. B.)

SHORTHOUSE, JOSEPH HENRY (1834–1903), English novelist, influenced by the Oxford movement (*q.v.*), whose "philosophical romance," ***John Inglesant***, is one of the few English examples of the novel of ideas. The eldest son of Quaker parents, he was born in Birmingham on Sept. 9, 1834. His education was interrupted by illness and at 16 he entered the family chemical works, but continued to read widely. Influenced by Ruskin and the Pre-Raphaelites, and attracted by Anglican worship and liturgy, in 1861 he joined the Church of England; the dichotomy between the quietist view of religion in which he was brought up and the sacramental view he adopted gives a particular colouring to *John Inglesant*. This, his first novel, begun in 1866, is set in 17th-century England and Italy, and discusses the conflicts between church and state, the Church of England and the Church of Rome, ritualism and simplicity, different views of the sacraments, etc., in long Platonic dialogues and disquisitions. It incorporates unacknowledged quotations from such 17th-century writers as Thomas Hobbes, John Aubrey, Miguel de Molinos and John Evelyn, and depicts with scholarly detail but Tractarian bias the atmosphere of the period, giving a notable picture of the community founded at Little Gidding by Nicholas Ferrar (*q.v.*).

It remained in manuscript until 1880, when 100 copies were privately printed. One came to the notice of Mrs Humphry Ward on whose recommendation Macmillan published it in 1881. Its success (9,000 copies were sold within a year) was due partly to the praise it received from T. H. Huxley, Cardinal Manning and Gladstone, and partly to its treatment of topical themes, but, by its quiet charm, its dignity and the devotional, mystical tone of its religious feeling, it continues to hold a higher place in the esteem of many readers than its purely literary quality perhaps merits.

Shorthouse's other novels (*Sir Percival*, 1886, etc.) were less successful, although revealing the same blend of Platonism, aestheticism and mysticism.

Shorthouse died at Edgbaston on March 4, 1903.

Bibliography.—*Life, Letters and Literary Remains*, ed. by his wife, 2 vol. (1905); J. E. Baker, *The Novel and the Oxford Movement* (1932); M. Polak, *The Historical, Philosophical and Religious Aspects of "John Inglesant"* (1933).

SHORT STORY, a kind of prose fiction, distinguished from the novel (*roman*) and the novelette (*nouvelle* or *novella*) by its compression and intensity of effect. More prescriptive definitions than this have been advanced, some of them so arbitrary as to place unattractive and unnecessary limitations upon a developing art form. For the short story, like the novel, is still in a process of development and perhaps ultimate definition. The serious short story of the 20th century might be visualized as occupying a square, the four corners of which are marked by the narrative essay or sketch, the lyric poem, the prose drama and the unit of local social history. Some short stories would be located in the centre of the square; others, although within the square, would be closer to one corner than to the others. Washington Irving's 19th-century "The Legend of Sleepy Hollow," with its slight, uncomplicated action, its embellishments of time and place and the immediate presence of the voice and personality of the

author, can only with difficulty be distinguished from a narrative essay or sketch. James Joyce's "The Dead," with its luxuriant evocation of sensuous images and its intensity of mood, differs from a lyric poem only in its expansiveness and its failing to fully utilize rhythm and sound. Ernest Hemingway's "The Killers," stripped as it is of overt comment or analysis, and making its effect primarily by the implications of dialogue and a few simple actions within a limited scene, could easily be produced as a one-act play. Finally, Theodore Dreiser's "Old Rogaum and His Theresa," concentrating as it does upon a conflict within an immigrant family in special economic and social surroundings, is akin to a chapter in a social history of New York city.

Early Forms of Short Fiction.—If it has been largely in the 20th century that the lyric and dramatic possibilities of the short story have been explored, the similarities of the short story to particularized history and to the expanded anecdote are traditional. These likenesses may be suggested by the origins of the words used to denote a short prose fiction: "story," with its roots in the Latin *historia*, suggests the relation of fictional accounts to the presentation of historical events; the English "tale" and the French "conte" suggest something told or recounted, and by implication the felt presence of the teller or narrator. Short stories, in the sense of short tales told by an oral teller, of course antedate the records of human history. The most primitive man undoubtedly could arrange a series of remembered events in a time sequence and thus have the rudiments of a story. Among the earliest writings of man are *Tales of the Magicians*, a collection of stories from ancient Egypt which probably date from about 4000 B.C.; similar collections may be found in the ancient writings of Arabian, Hindu, Greek and Hebrew cultures. It has often been pointed out that the Bible contains tales that would fit the present conception of the short story: the books of Ruth and Jonah, for example, or such parables in the Gospels as that of the Prodigal Son. The literature of the middle ages and the Renaissance abounds in short narratives in both prose and verse, of which the *Decameron* of Giovanni Boccaccio is the foremost example. Western European literature after the Renaissance has produced numerous fables, romances, tales and sketches, which kept a tradition of short prose narration alive.

Emergence of the Short Story.—It was not until the beginning of the 19th century, however, that the short story as a distinct literary form began to attract the attention of serious writers in large numbers. Almost simultaneously in Germany, the United States, Russia and France collections of short fiction began to appear. In Germany, E. T. A. Hoffmann published his exotic tales between 1814 and 1821; Johann Ludwig Tieck, who had begun publishing stories in the 1790s, published several collections in the 1800s. In the United States the publication of Irving's *The Sketch Book* in 1819 and 1820 marked the beginning of a long tradition in the American short story. One of the three tales in that collection, "Rip Van Winkle," has generally been regarded as the first American short story. In 1832 the first stories of Edgar Allan Poe and Nathaniel Hawthorne began to appear. With Irving, these two authors were to become the best American writers of the short story in the first half of the century. At almost exactly the same time, two Russians, Aleksandr Pushkin and Nikolai Gogol, turned from the writing of novels and the drama to the short story, where their attention to the details of ordinary life contrasted sharply with that of the fantastic and the legendary which had been exploited by the earliest German and American story writers.

Finally by 1830, three writers in France—Prosper Mérimée, Honoré de Balzac and Théophile Gautier—had begun a distinguished tradition of the conte which was to continue throughout the century. What is remarkable about this sudden flourishing of a literary form in several countries at approximately the same time is that all of these writers, in spite of their varying techniques and subjects, were united in their conception of the short prose narrative as a potentially important form of literary art and in their consequent exploration of the possibilities and limits of the short story as a genre. Indeed the term short story was not to appear very frequently until much later in the century. Even story was quite infrequent, although as early as 1824 Irving used "Strange Stories by a Nervous Gentleman" as a subtitle for an installment of his *Tales of a Traveller*. Tieck called one of his collections *Die Gemälde* (pictures); Irving called his stories sketches or tales; Poe called his tales or articles; Hawthorne used tales, sketches, even parables.

Why the conception of the short story as a new form should have come at just this time, relatively so late in the development of western literature, is somewhat difficult to explain. Possibly the short story could not be developed until the novel itself had reached the status of serious art and some degree of maturity in the latter half of the 18th century. The widespread experimentation with new forms as part of the romantic movement at the beginning of the 19th century may also be suggested as a contributing factor. In the United States the form found special favour, not only as a literary medium in the refinement of which the U.S. writer could participate from the very beginning but also as a type of writing admirably suited to publishing conditions in the new republic. There the flood of annuals or "gift books," which followed the first number of *The Atlantic Souvenir* in 1826, provided a ready market for short works which the U.S. writer, handicapped in the publication of novels by the international copyright situation, could supply on equal terms with British writers. From the annual gift books, which provided a first publishing outlet for Hawthorne, evolved the popular magazines, in which Poe's work most often appeared. Because magazine editors competed with each other for short fiction to fill the pages of their monthly issues, a whole new market was created. These editors probably adopted the sentiment expressed facetiously by Irving in a preface to his *Tales of a Traveller:* "If the tales I have furnished should prove to be bad, they will at least be found short; so that no one will be wearied long on the same theme." Later Poe expressed the importance of these economic circumstances when he argued that the short story was the child of the American magazine. Certainly the popular magazine, both in the United States and in Europe, has continued to be by far the largest outlet for short stories, consuming hundreds of thousands of them during a century and a half and creating various formulas for "the popular story," which provides ephemeral entertainment for readers without disturbing them unnecessarily, and conceals old plots and hackneyed ideas in ingeniously invented novelties of detail.

The importance of Poe in the history of the short story is that he used the magazine to insist that a short story was potentially a superb art form. It is true that such writers as Hoffmann, Irving and Gogol had recognized the rewards of attention to the artistry of the tale; but Poe in his famous review of Hawthorne's *Twice-Told Tales* in *Graham's Magazine* for May 1842 claimed that "the tale proper, in our opinion, affords unquestionably the fairest field for the exercise of the loftiest talent, which can be afforded by the wide domains of mere prose," reserving the highest order of excellence for the lyric poem. Furthermore, he formulated the first set of principles for the art of the short story in a famous paragraph:

> A skillful literary artist has constructed a tale. If wise, he has not fashioned his thoughts to accommodate his incidents, but having conceived, with deliberate care, a certain unique or single *effect* to be wrought out, he then invents such incidents—he then combines such events as may best aid him in establishing this preconceived effect. If his very initial sentence tend not to the outbringing of this effect, then he has failed in his first step. In the whole composition there should be no word written, of which the tendency, direct or indirect, is not to the one pre-established design.

Some of Poe's principles—coherence and design, for example—were hardly new, being those assumed for literary art from the time of Aristotle onward; yet their application to the short story indicated that it had grown by 1842 into a significant literary form. Moreover, if it is true that Poe's somewhat mechanical conception of composition and his emphasis on a "single effect" could in the hands of critics like Brander Matthews 60 years later lead to a falsely rigid reduction of the short story to certain "essential ingredients" which could be concocted for the popular magazines, it must be remembered that Poe achieved a notable

variety of works within his definition: the classic horror tale "The Cask of Amontillado"; the detective tale "The Purloined Letter"; and the tales of psychological exploration "Ligeia," "William Wilson" and "The Fall of the House of Usher."

The two other U.S. writers of this period whose work deserves mention, Hawthorne and Herman Melville, were more important as novelists than as writers of shorter works. Hawthorne in his *Twice-Told Tales* (1837) and Melville in *The Piazza Tales* (1856) added a moral ingredient to the short story which Poe's tales of effect lacked. Rich in symbol, proceeding from the depths of human experience, and appealing to the intellect as well as to the emotions, their work has an integrity and complexity which for many modern readers Poe's and Irving's have seemed to lack. Each of Hawthorne's stories, like the black cloth in his "The Minister's Black Veil," holds a "mystery which it obscurely typifies," and it examines the ambiguities of human life in a manner which Poe's "single effect" does not comprehend.

The Short Story in Europe.—While U.S. writers were taking advantage of their special circumstances to build a strong tradition of the short story, writers in France and Russia were no less active. In contrast to the romantic fantasy and eccentric distortions of Tieck and Hoffmann in Germany, or the U.S. variations of the tale of romance and terror in the comic Gothic of Irving, the psychological interest of Poe and the moral concern of Hawthorne, such French writers as Mérimée and Balzac were grounding their work in realism and emphasizing such clarity of observation, vividness of detail and precision of statement that the stories "stand and speak before the reader," the writer remaining impersonal and objective. This tradition of objectivity, which led the short story away from its similarities to the narrative essay or sketch, where the presence of the author's personality continuously is felt, toward the direct representation of the drama, where the incidents must reveal the meaning of the work implicitly rather than explicitly, has been the major contribution of the French story writers, not the early masters, but also those who continued this tradition much later in the century—Gustave Flaubert and Guy de Maupassant.

The Russian tradition, beginning with the stories of Gogol in *Dead Souls*, reached an early maturity in the work of Ivan Turgenev, whose first and perhaps finest collection of stories, *A Sportsman's Sketches* (1852), indicated the direction which the Russian story was mainly to take. These stories, grounded in the ordinary circumstances of peasant life as Gogol's had been, have little of the appearance of the striking combination of incidents leading to a climax which Poe had recommended in his review of Hawthorne's tales ten years before. Each story catches a character in a particularly revealing incident, one which illuminates the whole life of the individual in an impression which seems deceptively casual. In one of his best stories, "The Country Doctor," Turgenev seems to express wonder at the very method which he invented: "It's strange how things happen in life: you live with someone for a long time, you are on the best of terms, yet you never once speak to them frankly and from the heart; with someone else, you've hardly even got acquainted—and there you are: as if at confession, one or other of you is blurting out all his intimate secrets." The overheard revelation of the "intimate secrets" of a character or characters is the primary intention of Turgenev's stories, and the representation of character rather than the combination of striking incidents is his primary method.

Thus in the contrasting emphases of Poe and Turgenev two different approaches to the short story appeared, the one assuming that the proper method of the story was to invent incidents which when plotted to a suspenseful climax offered a sweeping total effect, and the other assuming that the proper method was to begin with the representation of characters who themselves seemed to suggest incidents that would reveal the quality of their lives.

This basic division can be seen again in the contrasting methods of the two most influential short story writers of the beginning of the 20th century—one French and the other Russian. Guy de Maupassant mastered the method of Poe, bringing to it the compression, the economy of detail and the vivid precision of style which were typical of the French story almost from the beginning. His ingeniously constructed plots and striking climaxes were imitated by writers on both sides of the Atlantic, to whom such a story as "The Necklace" seemed a perfect model. That the mannerisms and tricks of the Maupassant story should have been adopted by great numbers of writers of the popular magazine story and converted into a sterile formula does not deny the achievement of Maupassant himself, whose ironic pessimism and realistic examination of life set him apart from the writers who packaged his wares for mass consumption. The influence of Anton Chekhov, on the other hand, was not so much to be found among the writers of the popular story as among the large number of young writers of the 1920s in England and the United States, to whom the plotted story of Poe and Maupassant, as brought to a superficial polish in the tales of O. Henry, Jack London and Rudyard Kipling, seemed to eliminate the possibilities of individual experiment.

Chekhov's stories, like Turgenev's, focused on revealing moments in the lives of his characters, and their climax comes not so much in a striking incident as in a growing understanding of the nature of a character and his situation. A story he argued, should have neither beginning or end, for it was at these points that the author was tempted to impose an artificial neatness and certainty on the complexity of life. The unity for which he strove was not an external resolution of a complicated action, but rather an internal unity of revelation of character.

Each tradition, the Poe-Maupassant story emphasizing plotted action or the Turgenev-Chekhov story emphasizing revelation of character, could of course provide successful stories, for plot and characters are inextricably intertwined in a significant story. The best stories of the 20th century proceed from an organic theory of the form, for which Henry James became not only a tireless explicator but also a distinguished practitioner. In his important essay "The Art of Fiction" (1884) James argued that a piece of fiction "is a living thing, all one and continuous, like any other organism, and in proportion as it lives will it be found . . . that in each of the parts there is something of each of the other parts . . . What is character but the determination of incident? What is incident but the illustration of character? . . . It is an incident for a woman to stand up with her hand resting on a table and look at you in a certain way; or if it be not an incident I think it will be hard to say what it is. At the same time it is an expression of character." James's preoccupation with discovering the proper form for each work, in which each of its elements contributes fully to its effect and in which the total structure embodies its meaning, is reflected less in his immediate influence on his contemporaries than in the influence which his fiction and his criticism had on English and American writers after World War I.

The Short Story in English.—James's own contemporaries in the U.S. were developing two other schools of the short story, both of which seemed more promising at that time than they did several decades later. Near the beginning of James's career, the "local colour" movement produced hundreds of stories aimed at exploiting the regional peculiarities of the different sections of the United States. Among the best of the local colourists were Bret Harte and Mark Twain in the west, Hamlin Garland in the midwest, George Washington Cable and Joel Chandler Harris in the south, and Sarah Orne Jewett and Mary E. Wilkins Freeman in New England. At best, the movement provided its readers with genuinely imagined representations of the regional life of a nation only recently torn by civil war, and it extended the range of short fiction into localities not before explored by the short story writer. At worst, the local colourists merely dwelt upon the quaintness of local characters and dialect, and marketed an "atmosphere" applied with a broad brush. Near the end of James's career "the O. Henry manner" was in vogue. The stories of O. Henry, with their rush of incident, crackling style and startling trick endings, achieved for their author an immense popularity and a host of imitators who filled the popular magazines with stories written to his formula. Later critics have found his work to be lacking in intellectual depth and his central theme—the effect of coincidence

on character—scarcely worthy of the endless variations he played upon it; yet for many ordinary readers in the United States and England, O. Henry is pleasantly remembered as "a man who could tell a story."

Although storytelling has been a folk pastime in England for centuries and short fiction has been written in England from the time of "The Green Knight" of Arthurian romance on to the present, the English short story was quite undistinguished until late in the 19th century. The masters of the English novel—Sir Walter Scott, Charles Dickens, George Meredith and Thomas Hardy—occasionally attempted short works, but they gave little evidence of comprehending the potentialities of the form which was maturing in Russia, France and the United States. Short fiction filled the English magazines, but most of the stories were merely amusing anecdotes or sentimental and pious recountings of minor domestic crises.

During the 1880s, however, the influence of such American writers as Irving, Poe, Bret Harte and Ambrose Bierce began to be felt in the romances and fantasies of Robert Louis Stevenson, Oscar Wilde and the contributors to *The Yellow Book*. It was in Rudyard Kipling, however, that the short story in England found a talent comparable to Maupassant in France. Kipling's stories abounded in flamboyant effects and striking incidents of British colonial life; well plotted and colourful, they provided the models for many English writers during the first two decades of the 20th century. Yet it was not until after World War I that the short story in Great Britain really flourished. The major novelists—Joseph Conrad, James Joyce, E. M. Forster, Virginia Woolf and D. H. Lawrence—showed an awareness of the short story form that their 19th-century counterparts had lacked. Ironically, the two writers whose influence has been strongest on the 20th-century story were Joyce of Ireland and Katherine Mansfield of New Zealand. Joyce's *Dubliners* (1914) showed a remarkable ability to transmute the incidents of ordinary life into classic art through richness of imagery, objectivity and restraint. Katherine Mansfield's delicate stories, rendered in poetic prose and focusing upon internal, psychological conflicts, have an obliqueness of narration and a subtlety of observation that reveal plainly the influence of Chekhov.

Though probably not so influential in determining new courses for the short story as Joyce and Mansfield, W. Somerset Maugham undoubtedly had the widest public of any English short story writer throughout almost half of the 20th century. A sleek objectivity and an incisive dissection of human frailties are the marks of his stories; their sardonic comedy is an acid variation on the wry humour that characterizes many English stories. A later generation of writers—V. S. Pritchett, Graham Greene, H. E. Bates, Elizabeth Bowen and William Sansom—have demonstrated that the short story in England reached maturity by the middle of the 20th century, after scarcely 50 years of distinguished achievement.

The 20th-century short story in the United States has been equally rich, justifying Poe's prediction in 1842 that the form could encompass "a vast variety of modes or inflections of thought and expression." As in England, the major novelists—Willa Cather, F. Scott Fitzgerald, Hemingway, William Faulkner, John Steinbeck and Robert Penn Warren—were likely to be equally at home in the short story and the novel.

From Stephen Crane to Eudora Welty, the U.S. writer, whose only tradition sometimes seems to be to break with tradition, was constantly evolving new individual forms for his vision of life. His work has been marked by an intense devotion to craft, a thorough grounding in actuality without false sentiment or moralizing and an ability to discover the universal in the regional. His American "voice," a robust colloquial speech, has gone through successive stages of refinement in the style of Mark Twain, Sherwood Anderson and Hemingway. His preoccupation with the regional qualities of U.S. life, particularly the south (as in Faulkner, Warren, Katherine Anne Porter and Eudora Welty) and the midwest and west (as in Anderson, Steinbeck and Walter Van Tilburg Clark), has come not merely from the attraction of local colour but rather from the hope that the human spirit could best be caught at close range. His concern for his native scene has not prevented influences from Europe from being absorbed into the American short story, particularly the work of Thomas Mann, Franz Kafka, Katherine Mansfield, Joyce, Chekhov, Maupassant and Flaubert, and in turn the impact of the U.S. story has been widely felt in Europe.

SHOSHONE (SHOSHONI), a North American Indian group that in historic times occupied the territory from southeastern California across central and eastern Nevada and northwestern Utah into southern Idaho and western Wyoming. Comanche (*q.v.*) are a comparatively recent offshoot of Wyoming Shoshone. Shoshone, together with Southern Paiute-Ute and Northern Paiute, comprised the three divisions of the Basin-Plateau branch of the Shoshonean language. Shoshone dialects are so similar that speakers from Death Valley, Calif., have no difficulty conversing with Comanche.

Shoshone of historic times may be roughly divided into four groups: Western (unmounted) Shoshone, centering in Nevada, lacking horses, and early designated "Diggers" along with other far western Indians; Northern (mounted, or horse) Shoshone of northern Utah and Idaho; Wind River Shoshone in western Wyoming; Comanche in west Texas.

Western Shoshone had no band organization, and were divided into loosely affiliated family units that subsisted on wild seeds, small mammals, and insects. Each family was independently nomadic during most of the year and joined other families only briefly for rabbit drives, antelope hunts, or dancing. Hostilities were confined to feuds between families. A few Western Shoshone obtained horses after Europeans settled Nevada and Utah.

Wind River Shoshone and Northern Shoshone probably acquired horses as early as 1700, before Europeans occupied their lands. They formed bands of mounted buffalo hunters and warriors, and acquired such Plains Indian traits as tepees, skin clothing, and counting coup as war honours (*see* PLAINS INDIANS).

After acquiring horses, the Comanche split off from the Wind River Shoshone and moved south into Texas. Since raids on the Spaniards of the Southwest were the principal source of horses for Plains Indians, the Comanche developed predatory bands which were feared because they subsisted as much by plunder as by buffalo hunting.

Wind River Shoshone population is estimated to have been 2,500 in the early 19th century, and that of the Comanche 7,000. Northern and Western Shoshone together did not exceed 10,000 at that time. In the 1960s the combined total was about 7,500 for all four groups; most lived on reservations in territory they once held.

SHOSTAKOVICH, DMITRI DMITRIEVICH (1906–), the leading Russian composer of the Soviet era, was born in St. Petersburg on Sept. 25 (new style; 12, old style), 1906. During 1916–18 he studied at Glasser's School of Music and in 1919 entered the Petrograd conservatory, where for four years he studied the piano under Leonid Nikolaev and composition under Maximilian Steinberg. After leaving the conservatory he found it difficult to decide between the careers of virtuoso and of creative artist, but the remarkable success of his First Symphony (1926), not only in the Soviet Union but throughout Europe and the U.S., set the seal on his decision to concentrate on composition. His next works, the Second Symphony ("Dedication to October," 1927) and an opera based on Gogol's *The Nose* (Leningrad, 1930), were thoroughly contemporary in feeling—*The Nose* fully revealed Shostakovich's penchant for parody and the grotesque—

and were sharply criticized for their decadent "western" sophistication. In the Third Symphony ("First of May," 1931) and three ballets—*The Golden Age* (1930), *Bolt* (1931), and *The Limpid Stream* (1935)—Shostakovich chose Soviet themes and modified his musical idiom, though without appeasing his critics. His second opera, *The Lady Macbeth of Mtsensk* (after N. S. Leskov's story, later renamed *Katerina Izmailova*), after being hailed as a masterpiece on its production at Leningrad on Jan. 22, 1934, was two years later denounced by *Pravda* as "Muddle instead of Music." Awed by this severe official criticism, he withdrew and suppressed his Fourth Symphony while it was in rehearsal.

After almost two years of nearly complete silence Shostakovich produced "a Soviet artist's practical creative reply to just criticism" in the form of a Fifth Symphony, which was received with approval. The period immediately before the German invasion was marked by the first of his series of string quartets (1938), the Sixth Symphony (1939), the popular Piano Quintet (1940), and a large quantity of film music, a genre in which Shostakovich was prolific from 1929 onward. Within a few months after Russia's entry into World War II Leningrad was beleaguered and Shostakovich wrote the first three movements of the quasi-programmatic Seventh Symphony ("Leningrad") during the siege (1941). Monumental and heroic in conception, the symphony, first performed at Kuibyshev (1942), enjoyed enormous popularity at the time both in the U.S.S.R. and in the other Allied countries. Shostakovich turned from this score to another Gogol opera, *The Gamblers*, which he abandoned unfinished. Neither the similarly monumental Eighth Symphony (1943) nor the relatively flippant Ninth (1945) won anything like the approval accorded to the Seventh and, after another Communist pronouncement on musical policy in 1948, Shostakovich turned for a time from chamber music (quartets No. 2 and 3, Piano Trio) mainly to choral works, such as *Song of the Woods* (1949), and to film music.

Shostakovich visited the U.S. in 1949 and in 1958 he made an extended tour of western Europe, including Italy (where he had already been elected an honorary member of the Accademia nazionale di Sta. Cecilia) and Britain (where he received an honorary doctorate of music at Oxford). His most important later compositions include the problematic Tenth Symphony (1953), the monumental Eleventh and Twelfth (1957 and 1961), commemorating the insurrection of 1905 and the Revolution of 1917, and the Thirteenth (1962) consisting of choral settings of poems by Y. Yevtushenko; the 24 Preludes and Fugues for piano (1951); a Violin Concerto (performed 1955, though written much earlier), a second piano concerto (1957; the first, accompanied by trumpet and strings, dates from 1933); a cello concerto (1959); and five more quartets.

Although brilliantly gifted, Shostakovich from 1930 onward revealed in his work a conflict between, on the one hand, his natural inclinations toward the witty and lighthearted expressed in a pungent harmonic idiom and, on the other, the effort to produce music that, according to Soviet standards, should be optimistic, monumental, and "democratically acceptable."

SHŌTOKU TAISHI (574–622), regent of Japan, one of the most important contributors to development of Japanese civilization, who brought to it new political, religious, and artistic institutions, was a nephew of the empress Suikō. He became crown prince and regent in 593. By means of persuasion and political maneuver, he expanded the power of the imperial house, bringing back into its hands powers that had been delegated to the nobles.

A brilliant scholar, Shōtoku was instrumental in introducing Chinese culture to Japan. His motives were not entirely intellectual and aesthetic, however, for he saw in Chinese political institutions and technology a means of building a stronger central government in Japan. His 17-article constitution expressed the ideals of a centralized bureaucratic state on the Chinese order; he was thus the forerunner of the Taika reform. Shōtoku was a devout believer in Buddhism, and in order to spread that faith through the country he began the building of temples in areas far beyond the capital city. After his death, he was looked upon in popular belief as a Buddhist saint. *See* also JAPAN: *History*.

SHOT PEENING: *see* BLAST CLEANING AND SHOT PEENING.

SHOT-PUT, a sport in which a spherical weight is thrown or put from the shoulder for distance. It derives from the ancient sport of putting the stone. First to use a shot instead of a stone competitively were British military sports groups, and later the idea was adopted by civilians. While the weight varied from 8 to 24 lb., the 16-lb. (7.257-kg.) shot was adopted for men in Olympic Games, national and international competitions. Weight for women's competition is 8 lb. 13 oz. (4 kg.), and for high school girls 8 lb. A 12-lb. shot is used for high school boys' competition, ages 15–19.

Constant improvements in technique resulted in the doubling of record distances. The International Amateur Athletic Federation recognized the first official world record as 30 ft. 11½ in., by J. M. Mann of the United States in 1876. E. J. Borr of Great Britain surpassed 40 ft. in 1880 and Ralph Rose (U.S.) in 1909 became the first to exceed 50 ft. Speculation over man's ability to attain 60 ft. paralleled, in a lesser way, the topic of man's ability to run the 4-min. mile. Interestingly, the 60-ft. shot-put was achieved two days after Roger Bannister, the British runner, broke through the 4-min. barrier. Parry O'Brien (U.S.) put the shot 60 ft. 5¼ in. on May 8, 1954. In 1960 Bill Nieder (U.S. Air Force), who beat O'Brien in the Olympics that year, raised the world record to more than 65 ft. D. C. Long (Southern California Striders) won the 13th Olympic title for the U.S. with 66 ft. 8¼ in. at Tokyo in 1964 and on May 8, 1965, Randy Matson (Texas A. & M.) broke the 70 ft. barrier with a throw of 70 ft. 7 in. (21.718 m.).

In women's competition with the 4-kg. shot, Galina Zybina of the U.S.S.R. brought the record above 50 ft. when she won the 1952 Olympic championship. In 1960 Tamara Press of the U.S.S.R. pushed beyond the 55-ft. barrier with an Olympic record of more than 56 ft. and a world record of more than 58 ft. In 1962 Miss Press extended the world record to 60 ft. 10¼ in.; and in 1964 she raised the Olympic record to 59 ft. 6$\frac{3}{16}$ in. (18.307 m.).

The shot generally is made of solid iron or brass, although any metal not softer than brass may be used. It is put from a circle 7 ft. (2.135 m.) in diameter.

Technique.—The put is started at the back of the circle by shifting the weight of the body to the right foot with good balance, left knee bent and the left toes raised so that the spikes clear the ground. Next, the left knee is brought close to the right knee and the right leg bent gradually as the hips cross the circle. This method of starting the put enables the shot-putter to be in a correct position when he reaches the centre of the circle and thus able to start lifting the shot immediately. The shot is lifted via the medium of the leg muscles, and the put must always be made upward and not outward by a rhythmic movement of the arm muscles, which can be acquired by constant repetition.

Whereas it was conventional to start from a position at right angles to the direction of the put, O'Brien developed a style of beginning from a backward position. Thus he brought the implement around 180°, rather than 90°. He found that the longer one pushed the shot, applying force against a moving object, the longer the throw would be. *See* OLYMPIC GAMES.

SHOTTS, a town of Lanark, Scot., 18 mi. E of Glasgow by road, and on the Glasgow-Edinburgh Railway. Pop. (1961) 18,924. There are iron works, quarries, coal mines, hosiery factories, and engineering works. About 2 mi. NW, at Kirk of Shotts, is a BBC Scottish television transmitter.

SHOWBOAT, an American folk institution which for more than a century did much to relieve cultural starvation on river frontiers of the middle west and the south. The earliest of these entertainment boats penetrated regions where churches, schools,

newspapers and theatres had not gone.

The British-born actor William Chapman (1760–1841), built the first showboat, the "Floating Theatre" (14 by 100 ft.), at Pittsburgh, Pa., in 1831. He and his family floated from landing to landing, playing such dramas as August Friedrich Ferdinand von Kotzebue's *Menschenhass und Reue* (translated as *The Stranger*) and Shakespeare's *The Taming of the Shrew*, with music and dance specialties added. Upon reaching New Orleans late in winter, they junked the boat and returned by steamer to Pittsburgh, to repeat the pattern the next year. After Chapman's death, showboats first degenerated and then, because of the Civil War, disappeared entirely.

When showboats were revived (1878), they specialized in vaudeville and melodrama. Steamer tows and the calliope greatly increased territory and audiences, and Stephen Foster's songs added sentimental charm to their programs. Such boats as A. B. French's "New Sensation," McNair's "New Era," E. A. Price's "Water Queen," Thom's "Princess" and dozens of others, with seating capacities of 100 to 300, carried their rich cargoes of humour, music and simple emotion on every river of the Ohio-Mississippi system, from the narrow Monongahela in the northeast to the Atchafalaya bayous (creeks) in the south.

With the disappearance of river frontier conditions in the 1900s, and with the coming of better roads, automobiles and motion pictures, the decline of showboats was inevitable. To compete with land entertainment, they became larger and more elaborate. Menke's "Goldenrod" seated 1,400 persons and cost more than $35,000. The "Cotton Blossom," the "Sunny South" and Bryant's "New Showboat" were floating theatre palaces. All emphasized melodrama. With the burlesquing of these programs in the 1930s to attract sophisticated audiences, showboats ceased to perform their original function. The last one to travel the rivers in authentic pattern was the "Goldenrod" in 1943.

See Philip Graham, *Showboats: the History of an American Institution* (1951). (PH. G.)

SHOW JUMPING: *see* HORSEMANSHIP AND RIDING.

SHREVEPORT, a city of northwestern Louisiana, U.S., on the Red River, 317 mi. (510 km.) NW of New Orleans and 185 mi. (298 km.) E of Dallas, Tex. Shreveport is the centre of a standard metropolitan statistical area that covers Caddo and Bossier parishes. Pop. (1960) city 164,372; standard metropolitan statistical area, 281,481. (For comparative population figures *see* table in LOUISIANA: *Population*.) The area is slightly hilly except for parts of the river valley, has several lakes, and is forested with hardwood and pine.

Henry Miller Shreve, after clearing the Red River of a huge natural timber raft, founded the city in 1835 on lands obtained from the Caddo Indians at the head of navigation on the river. Cotton and river traffic formed the economic base, and Shreveport's association with nearby Texas is indicated by the many city streets named for heroes of the Texas revolution. At the end of the Civil War, Shreveport was the Confederate state capital and headquarters for the Trans-Mississippi forces of the Confederacy. Using logs to simulate artillery, its defenders constructed Fort Humbug to command the river; but the only major attempt to take the city was halted 40 mi. S at Mansfield. By 1900 the river was no longer used for commerce but railroads and cotton trade kept the city growing. Discovery of oil in the area in 1906 gave the city new impetus, and oil and gas continue to be of major economic significance.

A police jury administers Caddo parish except for the incorporated places of Shreveport, Vivian, Mooringsport, and Oil City. Of the 1960 population of the metropolitan area, 77.8% was urban, 18.5% rural nonfarm, and 3.7% rural farm; about 65% was white, 34% nonwhite, and 1% foreign born.

The area produces lumber, glass, metals, machinery, foods, and chemical and petroleum products. Cotton remains the chief farm crop, and the city is the wholesale and retail trade centre for the region known as the Arklatex. Educational facilities include a modern parish-wide public school system, a state trade school, and Centenary College of Louisiana, a Methodist liberal arts institution founded in 1825. Shreveport has a public library system, a symphony orchestra, a repertory opera company, and three amateur theatres. The Louisiana State Fair and Holiday in Dixie, a spring festival, are major annual events. Parks, golf courses, water sports and fishing on Cross, Caddo, and Wallace lakes, a municipal auditorium, a civic theatre and convention centre, a large stadium, and an indoor arena are available. Three highway bridges connect Shreveport with Bossier City (pop. [1960] 32,776), the location of Barksdale Air Force Base. (W. M. Lo.)

SHREW, a high-strung rodentlike mammal of the family Soricidae, order Insectivora. The common shrews or shrewmice of the northern hemisphere, belonging to the genus *Sorex*, are about the size of mice. They are distinguished externally by the long, pointed muzzle, which projects far beyond the lower lip. The small eyes are almost concealed by fur; the ears are short, broad, and provided internally with deep folds; the tail is usually slightly shorter than the body, generally quadrangular in section, and thinly haired, often with a small tuft at the tip. The fur is short and velvety, grayish or brownish in colour. On the side of the body there is a gland secreting a fluid with an unpleasant odour, a fact which renders shrews unpalatable to many larger predators. The short-tailed shrews, genus *Blarina*, common to eastern North America, are reputed to have a poisonous bite; the toxin, however, is only powerful enough to affect the shrews' favourite prey.

JOHN H. GERARD

AMERICAN SHORT-TAILED SHREW (BLARINA BREVICAUDA) FEEDING ON A SNAIL

Shrews feed largely on insects, snails, worms, and small mammals and are active day and night and in all seasons. They usually live in moist situations, burrowing in leaf mold in search of their food. They must feed almost continuously because of their very rapid metabolic rate and are said to consume their own weight in food about every three hours. In the sorecine shrews all teeth are tipped with red pigment, while crocidurine shrews of Africa, Asia, and part of Europe have white teeth. Skulls of shrews have no cheek arch. Several shrews are minute, among the smallest of mammals: the pygmy shrew (*Suncus etruscus*) may weigh as little as 2 g. and be less than 2 in. long. The largest species is probably one of the Asiatic water shrews, *Chimarrogale*, some 6 in. long, the tail 3 in.

The tree shrews are small, arboreal, insectivorous mammals found in southern Asia and in the islands of the Malay archipelago. They are squirrellike but have long pointed muzzles; their teeth are like those of the Insectivora. The common tree shrews (*Tupaia*) are dark olive brown with bushy tails. Pen-tailed tree shrews (*Ptilocercus*) are dark gray-brown with a black facial mask and narrow tail, ending in a featherlike tuft. Tree shrews, active during the day, feed on insects, some vegetable matter and the young and eggs of birds. Mammals of this type doubtless gave rise to the Primates (*q.v.*), and some authorities classify these forms with that order, others consign them to the Insectivora (*see* INSECTIVORE). (J. E. HL.; X.)

SHREWSBURY, EARLS OF. The title of earl of Shrewsbury was first held by the Norman baron, ROGER DE MONTGOMERY (d. 1094), who married the heiress Mabel of Belesme. In 1066 he remained behind in Normandy to assist in the government of the duchy, but was granted Arundel, Chichester, and other Sussex estates when he went to England in 1067. As a trusted councilor of King William, he was created earl of Shropshire in December 1074, a position which gave him palatine control of that county and placed him among the greatest of the Marcher lords; but he and his successors were usually styled earls of Shrewsbury. A great patron of monasticism, he became a monk in his newly founded abbey of Shrewsbury just before he died in 1094. His Norman inheritance passed to his eldest surviving son, Robert of Belesme (*q.v.*), and the title and the English lands went to Robert's younger brother, HUGH (d. 1098). With the earl of Chester, Hugh led the Norman conquest of north Wales and was killed by Viking raiders in Anglesey (1098). ROBERT OF BELESME

(*c.* 1052–*c.* 1131) succeeded as 3rd earl, but when he was deprived of all his honours for rebellion in 1102, the earldom became extinct. It was revived in 1442 for JOHN, LORD TALBOT (d. 1453) whose descendants have borne the title to the present day (*see* TALBOT; SHREWSBURY, JOHN TALBOT, 1st Earl of). As the possessor of the most ancient English earldom not merged in a higher dignity, the earl of Shrewsbury now ranks as the premier earl of England. (C. D. R.)

SHREWSBURY, CHARLES TALBOT, DUKE OF (1660–1718), English statesman who played a leading part in the Revolution of 1688 and was largely responsible for securing the Hanoverian succession in 1714, was born on July 24, 1660, the son of Francis (d. 1668), 11th earl of Shrewsbury. Brought up as a Roman Catholic, he was educated mainly in France during the years 1674–78. In 1679, influenced by John Tillotson, then dean of Canterbury, he joined the Church of England, thus qualifying himself, although under age, to take his seat in the House of Lords and to accept appointment as lord lieutenant of Staffordshire.

He first became active in politics in the reign of James II, when he resisted every temptation to return to the Catholic Church and became a leader in the conspiracy which led to the Revolution of 1688. The early meetings of the conspirators were held in his house in London; he was one of the famous seven who signed the letter of June 30, 1688, inviting William of Orange to come over with an armed force to England. In September he joined William in Holland and in November returned to England with his expedition, securing Bristol and Gloucester for him. In the Convention Parliament which assembled on Jan. 22, 1689, he advocated the elevation of William and Mary to the throne, and as soon as they had been proclaimed as William III and Mary II, he became a privy councilor and the secretary of state for the southern department.

Although moderately successful in office Shrewsbury was never happy there. Responsibility weighed upon him, and in the party rivalries following the Revolution he was unable either fully to support the aims of his Whig associates or to repudiate them altogether. On June 2, 1690, disgusted at the growth of Tory influence in the government, he resigned his secretaryship, and for four years, on the plea of ill-health, refused to resume office. This obstinacy exposed him to being called a Jacobite, an imputation somewhat supported by his association with the earl of Marlborough, whose conduct was giving great dissatisfaction to the king. On June 23, 1692, accordingly, he and Marlborough were struck off the Privy Council, and for a year thereafter he opposed the government, criticizing their conduct of the war and in 1693 advocating in the House of Lords a Triennial Bill, the first of a series which led to the Triennial Act of 1694. Nevertheless, William still liked and trusted him, and on March 2, 1694, when the Whigs were regaining influence at court, he accepted office as secretary of state for the northern department, transferring shortly afterward to the southern department. On April 25, 1694, he was made a knight of the garter and on April 30 was created duke of Shrewsbury.

CHARLES TALBOT, DUKE OF SHREWSBURY. PORTRAIT BY THE SCHOOL OF SIR GODFREY KNELLER, ABOUT 1685

His second period of office, though longer, was no more satisfactory than his first. Ill-health, real or imaginary, continued to worry him, and his chief energies were directed toward securing permission to retire. Although appointed one of the lords justices for the administration of the country during the king's absences on the continent in 1695, 1696, and 1697, he was accused during these years by the conspirator Sir John Fenwick and by the informer Matthew Smith of complicity in Jacobite intrigues, and he practically ceased to take any part in the government. On Dec. 12, 1698, he was allowed to resign his secretaryship, accepting in October 1699 the less responsible post of lord chamberlain; but this too he resigned on June 20, 1700.

Leaving England in November 1700, Shrewsbury spent the next five years in travel on the continent. On his return early in 1706 he became increasingly dissatisfied with his former Whig associates, and in 1710 went over to the Tories. He was appointed lord chamberlain on April 14 and a privy councilor on April 16, 1710, lord lieutenant of Ireland on Sept. 22, 1713, and lord high treasurer on July 30, 1714, when Queen Anne was on her deathbed. This last great office enabled him to exercise a decisive influence in the peaceful recognition of George I, who appointed him groom of the stole and keeper of the privy purse on Sept. 26, a privy councilor on Oct. 1, and lord chamberlain on Oct. 17, 1714. Shrewsbury died in London on Feb. 1, 1718, when his dukedom became extinct and his earldom passed to a cousin.

Shrewsbury was regarded as one of the finest and most cultured gentlemen of his day, but an excessive sensitiveness and a reluctance to face the harsh realities of life greatly impaired his effectiveness as a statesman. At the Revolution and on the death of Anne he pursued a bold and determined policy, but as a rule his attitude was weak and vacillating. His declaration that if he had a son he "would sooner breed him a cobbler than a courtier, and a hangman than a statesman," is a reflection on himself no less than on his political world.

See T. C. Nicholson and A. S. Turberville, *Charles Talbot, Duke of Shrewsbury* (1930); D. H. Somerville, *The King of Hearts* (1962). (A. Bo.; X.)

SHREWSBURY, JOHN TALBOT, 1ST EARL OF (*c.* 1384–1453), English soldier, celebrated for his exploits in the Hundred Years' War, was the second son of Richard, 4th Baron Talbot, and Ankaret, heiress of the last Lord Strange of Blackmere. By the death of his elder brother Gilbert's daughter Ankaret (1421) he acquired the baronies of Talbot and of Strange. In or before 1433 he married his second wife, Margaret (d. 1467), eldest daughter of Richard Beauchamp, earl of Warwick, and coheiress of the barony of Lisle.

After campaigns in Wales between 1404 and 1413, Talbot served as lieutenant of Ireland from 1414 to 1419. He was later to be justiciar of Ireland (1425) and lieutenant again (1445–47). In these offices he showed great vigour: the Irish said that "there came not from the time of Herod any one so wicked in evil deeds."

After 1419, however, most of Talbot's career was spent in France, where he became one of the foremost English captains. He fought at Verneuil in 1424 and took part in the siege of Orléans in 1429. His rashness was chiefly to blame for the English defeat at Patay in June 1429, when he was captured by the French. Released in 1433, he took Clermont in 1434 (the countship was then assigned to him), was present at the siege of Saint-Denis in 1435 and suppressed the revolt of the Pays de Caux in 1436. Henry VI made him a marshal of France. The mainstay of the English cause in France for the next five years, Talbot defeated the Burgundians before Le Crotoy in 1437 and took Harfleur in 1440. In May 1442, on a visit to England, he was created earl of Salop (Shrewsbury was the name that he himself used for the title), but the next winter, before Dieppe, he "fared so foul with his men that they would no longer abide with him" and was forced to raise the siege. His fighting qualities made him something of a popular hero: in the rhymes of the day he was "Talbot our good dog," whose valour was frustrated by the duke of Suffolk's treason.

After the fall of Rouen in October 1449, Shrewsbury was held for a time as a hostage by the French (1449–50); a pilgrimage to Rome was stipulated as a condition of his release. In command of the expedition for the relief of Gascony, he landed in the Médoc in October 1452; the Bordelais rose in his favour and Fronsac fell to him in the summer of 1453. The French, however, laid siege to Castillon. Shrewsbury hurried to its relief and on July 17, 1453, attacked the enemy in their entrenched camp without waiting for his artillery. He and the flower of his troops were killed, and English rule in Aquitaine ended with them. (T. B. P.)

SHREWSBURY, an ancient market centre, municipal borough and the county town of Shropshire (Salop), Eng., in the Shrewsbury parliamentary division, 153 mi. N.W. of London by road. Pop. (1961) 49,566. Area 12.7 sq.mi. (32.9 sq.km.). Its position in relation to the routes leading into Wales and along the border has made it a town of great importance. The old and central part of the town lies almost entirely on a peninsula within the remarkable southward loop described by the river Severn. The strategic position of this peninsula rising above the Severn flood lands was recognized from the time of the princes of Powys, who made it their seat, called Pengwern, in the 5th and 6th centuries. At the end of the 8th century it was engulfed in the provinces of Mercia and given its Saxon name Scrobbesbyrig, from which comes Shrewsbury. In the reign of Edward the Elder it had a mint, and in Domesday Book it is styled a city. After the Norman conquest, Shropshire was granted to Roger de Montgomery, who made Shrewsbury his headquarters and founded the abbey. At about this time, alternative names arose, Sloppesbury or Salopsbury, from which comes the modern Salop. In the next 200 years it was frequently involved in wars with the Welsh, and in 1283 Edward I called an assembly of parliament to meet at Shrewsbury. In 1403 the battle of Shrewsbury was fought close to the town on the north side, when Henry IV by defeating the Percys consolidated his position on the throne. During the late middle ages and again in Tudor and Elizabethan times the establishment of law and order in the Marches and trade with the Welsh in wool and flax resulted in a period of great prosperity. In the Great Rebellion Shrewsbury supported the king, who took up his quarters there in 1642, but the town was captured by parliament in 1645. Subsequent development was continuous and Shrewsbury became the cultural, business and transport centre for a large area of surrounding country.

Shrewsbury is a borough by prescription. The town possesses more than 30 royal charters from the charter of Richard I (1189) to that of James II (1685) and earlier charters were granted by Henry I and II. The charter of Charles I gave to the town a new constitution, and under its authority the first mayor was elected in 1638. The borough returned two members to parliament from 1394 till 1885, when the number was reduced to one. It is now included in the Shrewsbury division of Shropshire.

There are many buildings, streets, lanes and "shuts" of architectural and historic merit, including 15th- and 16th-century timber framed houses of which Ireland's mansion, Owen's mansion, the Abbot's house and Rowley's house are outstanding examples; the latter contains a museum of Roman antiquities from the nearby Roman-British city of Uriconium. The old Market hall is a fine stone building dating from *c.* 1596; there are also many Georgian and regency houses. A considerable length of the old town wall, including one of the watchtowers, still remains. Within the loop of the river (but outside the town walls) is a public park called the Quarry. Over its two ancient bridges, the English and the Welsh, the town spreads east into Abbey Foregate and around Abbey church and west into Frankwell on the Welsh side. In the Mount, at the top of Frankwell, Charles Darwin was born. St. Mary's church, on high ground south of the castle, is a noble building with a lofty tower and spire dating from early Norman to Perpendicular. It has some remarkable stained and painted glass, including the great Jesse window of English glass dating from about 1345; the St. Bernard glass from the Abbey church of Altenburg, attributed by some to Albrecht Dürer (1471–1528); and 15th-century glass from the cathedral of Treves. St. Alkmund's, St. Julian's and St. Giles' are old foundations, much altered subsequently. Old St. Chad's church, dating mainly from the 12th century, was largely destroyed by the fall of the tower in 1788, and only the 15th-century Lady chapel remains. The new St. Chad's church erected in 1790–92 on another site is built to a circular plan. The restored Abbey church (Holy Cross) retains its massive Norman nave, built of deep-red sandstone, and two Early English arches and a Decorated western tower; of the monastic buildings little is left, save a remarkable roofed outdoor pulpit of ornate Decorated work. Shrewsbury is the seat of a Roman Catholic bishop.

A fortification of some sort probably existed on the site of Shrewsbury castle before the Norman conquest, but the first reliable evidence of a castle being constructed there is in 1067. In 1071 it was given to Roger de Montgomery, then made earl of Shrewsbury, who continued working on it, and it was entirely rebuilt by Edward I. It was held for the king in the Great Rebellion but fell to parliament in 1645. It continued fortified until the reign of James II, but subsequently came into private ownership. The castle was converted to residential use by Thomas Telford toward the end of the 18th century. In 1924 it was bought by the Shropshire Horticultural society, restored as nearly as practicable to its 14th-century condition, and given to the corporation; it is used as a council chamber.

Shrewsbury school (founded by King Edward VI in 1552) occupied buildings opposite the castle until 1882, when it was moved to Kingsland, south of the river, formerly the scene of the Shrewsbury show, a pageant held during the festival of the Trinity. The old school buildings in the town centre were taken over by the corporation and are now used as a library, museum and art gallery. The cross at the junction of Pride hill and St. Mary's street, on the site of the original High cross, was given by the school to the town in 1952 to commemorate the 400th anniversary of the school's foundation.

The cattle market, one of the busiest in England, was enlarged and moved to the north of the town in 1959. Also in the north are most of the main industries which include locomotive rolling stock and general engineering; the manufacture of machine tools, safes and electrical equipment; and malting. (S. R. H. L.)

SHRIKE (BUTCHER-BIRD), a robust, predacious bird, about thrush size, with a heavy bill hooked at the tip. Shrikes belong to the songbird family Laniidae, which contains about 73 species. Their plumage is usually boldly patterned and varies from gray, white, and black to browns, greens, and reds. Their call notes are harsh but their song may be pleasing. Their nests are rather bulky structures, with many twigs in them, and the eggs are spotted. The distribution of the family covers Africa, where most species live; Europe and Asia to New Guinea (one species); and North America (two species).

The loggerhead shrike (*Lanius ludovicianus*) is the common American species, found from southern Canada to Mexico. It is gray above, white below, with a black mask, and is about nine inches long. The more northern birds retire southward in winter. The northern shrike (*L. excubitor*) is similar but larger (ten inches long), with fine barring on the breast. It breeds in northern Canada and Alaska, as well as in the Old World. Some winter in the northern United States.

Typical shrikes sit upon vantage points, hawklike, watching for their prey of large insects, small reptiles, mammals, or birds. Though predacious in habit, they lack strong feet for holding their prey and some species impale their food on thorns, sometimes leaving part of it uneaten. This fancied resemblance to meat in a butcher shop is the reason for one of their common names. Certain bush shrikes and helmet shrikes of Africa are only doubtfully placed in this family. Birds of an unrelated Australian family of butcherbirds and bell magpies also have the habit of impaling food on thorns. The vanga shrikes of Madagascar and the cuckoo shrikes, widespread in the warmer parts of the Old World, form two other unrelated groups of songbirds. (A. L. RD.)

SHRIMP, a crustacean distinguished from such other larger long-tailed members of their order (Decapoda) as lobsters and crayfishes. The most obvious features of shrimp are the long legs, weak claws, and laterally compressed abdomen.

Although most species are quite small, some even microscopic, a few reach a length of up to eight inches. Commercial fishermen usually refer to larger individuals as prawns and to smaller ones as shrimp. Shrimps (suborder Macrura) differ in greater development of the paddlelike limbs of the abdomen used in swimming and in their thin and sometimes fragile shell or exoskeleton. Like other crustaceans, shrimps wear their skeleton on the outside of the body and, in order to grow, must cast off this shell and replace it with a new and larger one. In the process of shedding, all of the hard structures of the shrimp are cast off and renewed.

The common shrimp swims in a forward direction by the use of the pleopods or abdominal feet. When frightened or when rapid movement is desired, the shrimp with a flexing of the powerful, muscular abdomen, can propel itself backward with remarkable speed and also can leap clear of the water.

Shrimp occur on mud bottoms of inshore and offshore waters in many parts of the world. Important fisheries operate in European, North American and Asian waters. Although often thought of as a warm-water shellfish, shrimp are also found in northern seas, and there are commercial shrimp fisheries in the waters off Norway, Greenland and Alaska. Considerable effort was expended in the search for new shrimp grounds in many parts of the world following World War II, and important new fisheries for the brown-grooved shrimp (*Penaeus aztecus*) and the pink-grooved shrimp (*Penaeus duorarum*) were developed in the Gulf of Mexico. A red shrimp, *Hymenopenaeus robustus*, was found in the deeper waters of the gulf at depths of 180 to 350 fathoms.

There are several hundred species of shrimp. The catch of species of *Penaeus* probably exceeds that of all other crustacean fisheries in magnitude and importance. The world's greatest shrimp fishery, based principally on species of *Penaeus*, is in the Gulf of Mexico, where several hundred million pounds of these shellfish are taken annually by United States, Mexican and Cuban fishermen.

Shrimp are taken in a variety of ways—with hand or cast nets, baited traps, haul seines, stake or channel nets set in tideways and with boat-drawn beam and otter trawls. The trawls, which account for the major portion of the world catch, consist of large, baglike nets which are dragged over the floor of the ocean, scooping up the shrimp in their path.

Shrimp are marketed fresh, frozen, dried, canned and cooked-and-peeled. Shrimp bran, a by-product, is manufactured from dried heads and hulls and sold for animal feed. Development of machines for removing the hulls from the shrimp meat, and the production of fresh-frozen and frozen-breaded shrimp, have assisted in a remarkable expansion in the market for shrimp in the U.S., the world's largest producer and consumer of shrimp.

River shrimp or prawns of the genus *Macrobrachium* (*Palaemon*), found in most tropical countries, are also much used for food. (E. A. Pr.)

SHRINE, THE (Ancient Arabic Order of Nobles of the Mystic Shrine): *see* Freemasonry: *Appendant Orders*.

SHROPSHIRE or Salop, an English county bordering on Wales, with Cheshire to the north, Staffordshire to the east, Worcestershire and Herefordshire to the south. The geographical area is 1,347 sq.mi. Both names, Shropshire and Salop, derive from O. E. Scrobbesbyrigscir (shire with Shrewsbury as its head), Salop being an abbreviation of a Normanized form, Salopescira.

Physical Features.—Shropshire is crossed by the Severn, which divides the hilly south and west from the undulating plain to the north and east. The upland is composed of a series of ridges including Wenlock Edge, View Edge, Stiperstones, and Stapeley Hill, and hogbacks (Ragleth, Caradoc, Lawley, and the Wrekin), all running from northeast to southwest with deep valleys between them. Among them lies the Longmynd Plateau (1,696 ft.); south of Corvedale is a triangular plateau with two tabletopped heights, Brown Clee (1,790 ft.) and Titterstone Clee (1,749 ft.). A third mass of high ground, Clun Forest, lies between the rivers Clun and Teme. The northern plain (about 200 ft. or less) is broken by a band of sandstone knobs (Nesscliff, Grinshill, Hawkstone). Streams, such as the Tern, have little fall, and large areas were formerly marsh (*e.g.*, the Wealdmoors). Peat mosses (Whixall) and meres, especially near Ellesmere, Whitchurch, and Baschurch, give variety to the landscape. The eastern plain has been cut by rivers—the Worf, Bowhill Brook, Claverley Brook, etc.—into a series of valleys and low ridges (Shatterford, Tuckhill, High Rock) running NNW–SSE.

The geological pattern runs on similar lines, older rocks being found in the uplands and later rocks mainly under glacial drift in the plain, but this pattern was broken by volcanic upheaval. The main series of rocks are: Precambrian in Longmynd, Wrekin, and Ercall districts; Cambrian at Church Stretton; Ordovician in the Shelve area and a strip north of Wenlock Edge; Silurian in Wenlock Edge, Corvedale, View Edge, Clun Forest, and the Ludlow districts; Carboniferous limestone poorly represented but seen near the Wrekin, at Lilleshall and Llanymynech (four small Coal Measure Basins: Chirk, Hanwood, with continuation northwest, Coalbrookdale, and Wyre Forest). Trias is found principally north of the Severn above Shrewsbury, north of Wellington, and east of Shifnal and Bridgnorth. A small area of Lias is exposed around Prees; and glacial drift covers most of the plain. The soil and vegetation are as varied as this geological pattern would suggest. The climate is usually mild and humid, though very low winter temperatures have been registered at Shawbury.

History.—Considerable prehistoric traffic through Shropshire is indicated by portable antiquities of late Neolithic and Bronze ages (collections in Rowley's House, Shrewsbury; Clun and Ludlow museums) and by field monuments of the Bronze Age, *e.g.*, round barrows on the Longmynd and Oldfield near Ludlow, stone circles on Stapeley Hill, and remains in the Clun region. Hill forts of Early Iron Age character abound, especially the Bury ditches, Hopesay Burrow Camp, the two Caer Caradocs, the Wrekin, Bury walls, and Old Oswestry. Related island sites—the Berth, Baschurch, and Kynnersley Wall—were possibly occupied later.

A Roman legionary fortress existed in the 1st century at Viroconium (Uriconium), later the cantorial capital of the Cornovii and one of the largest towns in Britain. There were small towns or posting stations; *e.g.*, Uxacona (Oakengates). The country appears to have been sparsely cultivated, with farms at Acton Scott, Linley Hall, Cruckton, Yarchester, etc., but silverbearing lead ores and outcrop coal were exploited.

The Saxon conquest was marked by the construction of Watt's Dyke and Offa's Dyke. Anglo-Saxon villages are recognizable by their names, terminating in "bury," "ton," "ley," etc., while Celtic place-names include elements like "pentre," "llan," "tre"; and Offa's Dyke is generally the linguistic boundary. Some Welsh elements, however, may be attributed to later infiltration which has gone on since the 11th century.

After Danish incursions had been finally repulsed, Edward the Elder divided Mercia into shires, and Shrewsbury became a mint town and coins were struck there until the reign of Henry III. At the Conquest, large areas of Shropshire were set aside as forests, or hunting grounds, subject to special forest jurisdiction such as those of Morfe, Mount Gilbert, Shirlett, Clee, and Stiperstones. Roger de Montgomery was given extensive estates for the defense of the border. A double line of castles against the Welsh was established during the 12th and 13th centuries, and the history of medieval Shropshire is a chronicle of Welsh incursions and baronial rebellions.

All Shropshire's religious houses were for men. The most important (with foundation dates) were: Benedictine at Shrewsbury (1083) and Bromfield (refounded 1155); Cluniac at Wenlock (refounded 1080); Cistercian, originally Savigniac, at Buildwas (1135); Augustinian canons at Haughmond (*c.* 1135), Wombridge (*c.* 1130), Chirbury (from Snead) in the late 12th century, Lilleshall (Arrouaisians, from Donnington Wood; *c.* 1144); Grandmontines at Alberbury (*c.* 1220–1441); Templars at Lydley Heys (*c.* 1158–1308); Hospitallers at Halston (*c.* 1221); Dominican friars at Shrewsbury (1222); Franciscan friars, also at Shrewsbury (1245–46) and at Bridgnorth (1244); Augustinian friars at Ludlow (1282), Shrewsbury (1298), and Woodhouse near Cleobury Mortimer (1250); Carmelites at Ludlow (1349).

The Midland system of three open fields was general in Shropshire, but some traces of Welsh land custom are found.

The high quality of Shropshire wool brought prosperity in the 13th century, Ludlow, Shrewsbury, and Bridgnorth being the main centres. As trade grew, Shrewsbury became established as the principal market for an area including much of North Wales. There was plenty of heath available for sheep, and therefore no outcry was made against conversion of common field to sheepwalk. But Welsh raids, plague depopulation, and bad seasons brought a decline in arable farming. In areas of high rainfall, cattle raising became important. From the 15th to the 17th centuries there are indications of a general increase in the size of

holdings, piecemeal inclosure of common fields, and some attempts to drain and enclose marshes and wastes.

A prerogative court, the council in the Marches of Wales, was established about 1473, with headquarters at Ludlow and with jurisdiction in Wales and the four border counties to check disorder and provide quick, cheap, effective remedies for local litigants. It was suppressed in 1642, reestablished in 1660, and abolished in 1689.

On the outbreak of the Civil War many families declared for the king, who came in person to recruit, but Puritan influence divided the north and extreme south of the county. While Shrewsbury and Bridgnorth stood siege for the king, Wem and Hopton Castle stood siege for Parliament. Fortified country houses were skirmishing centres. After the Battle of Worcester in 1651, Charles II in his escape found many Shropshire friends.

In 1708 Abraham Darby I went to Coalbrookdale and developed his new method of smelting ironstone with coke from pit-coal. He found a tradition of ironworking, local supplies of ironstone, sulfur-free coal, limestone, and charcoal, an ideal site with water power in the Dale, and water transport on the Severn. In the 18th century, the Darbys, the Reynolds, John Wilkinson, and others introduced many improvements and made Shropshire the greatest iron-producing area in England. The first cast-iron bridge was erected at Ironbridge in 1779; the first iron-built boat floated on the Severn in 1787; one of the first experimental locomotive engines for use on a railway was built by the Coalbrookdale Company for Richard Trevithick in 1801. In the same period, Caughley and Coalport were producing fine china, and Broseley became noted for churchwarden pipes.

The county is celebrated in the famous anthology of poems, *A Shropshire Lad*, by A. E. Housman (1859–1936).

Architecture.—Good examples of ecclesiastical, military, and domestic architecture are to be found in Shropshire. The development of castle-building techniques from the 12th to 14th centuries may be studied at Ludlow, Clun, Bridgnorth, Shrewsbury, and Hopton castles, where considerable portions survive. Ludlow and Shrewsbury retain parts of their town walls. In domestic architecture, Shropshire possesses outstanding examples of town and country houses of every period from the 13th century. Shropshire had no dominant noble family but many ancient county families, no great seat but many fine country houses. Stokesay (*c.* 1260–80) and Acton Burnell (1283) show the fortified manor house; the Old Mint, Shrewsbury, and Forester's Lodge, Millichope (*c.* 1280), are comparable town and country dwelling houses; the Provost's House, Edgmond, is 14th century, and the Abbot's House, Shrewsbury, dates from about 1450. Many Shrewsbury houses are partly medieval. There are numerous Elizabethan country houses, either half-timbered (Pitchford, *c.* 1570) or stone, for example, Benthall (1580), Wilderhope (1586), Condover (*c.* 1590). Moreton Corbet (early 17th century) is a magnificent ruin. A great building period (*c.* 1670–1730) produced such houses as Longnor (1670), Court of Hill (1693), Ludstone (1685), Cound (1704), and Davenport (1726). Ludlow and Shrewsbury are rich in 18th-century townhouses.

Population and Administration.—The population of the county in 1961 was 297,466. There are six municipal boroughs: Shrewsbury, the county town (pop. 1961, 49,566), Wenlock (14,935), Oswestry (11,215), Ludlow (6,796), Bridgnorth (7,552), Bishop's Castle (1,228) (*qq.v.*); and nine urban districts. In 1963 a New Town (*see* New Towns) was planned at Dawley to accommodate surplus population from Birmingham.

Shropshire is divided ecclesiastically between Lichfield and Hereford dioceses. It is in the Oxford circuit, and assizes are held at Shrewsbury. It has one court of quarter sessions, Shrewsbury alone retaining its commission of the peace, and eight petty sessional divisions. There are four parliamentary divisions: Ludlow, Oswestry, Shrewsbury, and the Wrekin.

Shropshire has three pre-Reformation grammar schools (Ludlow, Oswestry, and Bridgnorth) and three more founded in the 16th century (Whitchurch, Shrewsbury, and Market Drayton).

The Royal Salop Infirmary was founded in 1745. The Sir Robert Jones and Dame Agnes Hunt Orthopaedic Hospital at Gobowen, the first of its kind and a model for others, grew from small beginnings at Baschurch in 1904.

The Economy.—Shropshire is mainly an agricultural county. Holdings vary from farms of 1,000 ac. or more to highly efficient small holdings. About 80% of the area is under crops and grass; the chief crops are wheat, barley, oats, sugar beet, and potatoes, and cattle, sheep, pigs, and poultry are kept.

The southwestern uplands are devoted mainly to cattle and sheep raising, the native sheep breeds being Clun Forest and Kerry Hill. Shropshire sheep are bred in the lowlands. The indigenous beef breed is the Hereford, of which there are many famous herds. In the northern plain, dairy farming is the main activity. The predominant dairy breed is the British Friesian, followed by the Ayrshire and Shorthorn. The main cattle market towns are Shrewsbury with a fine new market, Oswestry, Wellington, Bridgnorth, Ludlow, and Craven Arms; sheep sales at Craven Arms are among the biggest in the country.

The most heavily wooded district is the southwest, where pine and spruce are found on higher ground, larch and mixed woods on slopes, and hardwoods in valleys. Northeastern Shropshire lacks woodland but is heavily timbered with hedgerow trees. Some fine woods are found in the Severn Valley below Buildwas, ending with a large remnant of Wyre Forest, as yet oak and coppice. The National Trust owned 1,445 ac. and protected 485 ac. in 1964.

Ironfounding and engineering are major Shropshire industries. In addition to constructional engineering, typical products are large castings, machine tools, locomotives, motor vehicles, wheels and chassis, steel furniture, safes, agricultural machinery, grates, and cookers. Other factories produce radios, toys, mats, lenses, aluminum pans, carpets, and clothing. The principal collieries working in the 1960s were Granville, Madeley Wood (Coalbrookdale coalfield), Highley (Wyre coalfield) and Ifton Heath (Chirk coalfield); some National Coal Board opencast working; and small private pits. Fireclay is excavated, and a large number of refractory products are made. Agricultural limestone is quarried in the Wenlock area, dolomite at Llanyblodwel, and road stone at Titterstone Clee, Squilver, Pontesbury, Maddocks Hill, etc.; but the best Grinshill freestone and Stiperstones lead and barites veins are exhausted. Maltings, breweries, creameries, and a sugar factory use local agricultural products.

The Severn was once navigable for barges up to Welshpool, and in the 18th century a brisk trade was carried on between Shrewsbury and Bristol, while a canal network connected the Severn with the Dee, Mersey, and Stour. Both rivers and canals fell into disuse in favour first of railways and then of road transport.

SHROUD OF TURIN, a linen cloth about 14 ft. 3 in. long and 3 ft. 7 in. wide, preserved since 1578 in the cathedral of Turin, Italy, and purported to be the burial cloth of Jesus. In 1898, at a public veneration, the first photographic plates were made of it, and these indicated that the image on the shroud—the front and back of a human body, marked with the stigmata—was a negative. After studying this evidence, two professors of biology presented to the Académie des Sciences in 1902 their conclusions that the image on the shroud is not a painting, that it is actually the imprint of a human body and that the image is that of the body of Jesus Christ. The authenticity of the shroud, however, has always been a matter of controversy. Its history cannot be traced further than the middle of the 14th century.

See Werner Bulst, S.J., *The Shroud of Turin* (1957); P. Scotti-A. Vaccari, S.J., in *Enciclopedia Cattolica*, vol. xi, col. 692–697, with detailed bibliography (1953). (E. J. L.)

SHROVE TUESDAY, the day immediately preceding Ash Wednesday (with which Lent begins in the Western church), may fall on any date between Feb. 2 and March 9, according to the date of Easter. Shrove, derived from *shrive*, refers to the confession of sins usual in the middle ages as a preparation for Lent. This origin is clear from many medieval documents. Thus an Anglo-Saxon translation of Theodulf of Orléans' *Capitula* says: "In the week immediately before Lent everyone shall go to his confessor and confess his deeds and the confessor shall so shrive him as he then may hear . . . what he is to do" (that is, as penance). Many customs connected with Shrove Tuesday were so deeply embedded in popular life that they continued in Protestant countries long after the Reformation. The most widely known of these customs is that of eating pancakes (the day is often known as pancake day). It is almost the sole relic of the merrymaking customary before the fast of Lent began, but there was originally a practical reason for the popularity of the dish on this day: it served to use up eggs and fat which were prohibited foods during Lent. Though Shrovetide corresponded with the carnival (*q.v.*) usual in European countries at this time (*Mardi gras* in French, *fetter Dienstag* in German), it never attained in England the proportions of the carnival. The day was usually kept as a holiday; games of football were common, together with throwing at cocks, and all sorts of horseplay took place in schools, universities and among apprentices. "They presently (like Prentises vpon Shroue-tuesday) take the lawe into their owne handes and doe what they list" (Thomas Dekker, *The Seuen deadly Sinnes of London*, 1606). The previous day was known in England as Collop Monday from the practice of eating collops of bacon and eggs.

See Herbert Thurston, *Lent and Holy Week* (1904). (L. C. S.)

SHUBERT, LEE (1875–1953), U.S. theatre manager and producer, was born at Syracuse, N.Y., on March 15, 1875. With his brothers SAM S. (1876–1905) and JACOB J. (1880–1963), he formed the Shubert Theatre Corporation, which came to control a large chain of theatres throughout the United States. The Shuberts began as theatre managers in Syracuse, where they organized several touring companies for the comedies of Charles A. Hoyt. In 1900 they leased the Herald Square Theatre in New York City and proceeded to acquire other theatres, from which grew the vast theatrical empire that once was estimated to be worth $400,000,000. Impetus for the growth of this empire came early from David Belasco and other independent producers during the struggle against the theatre trust, headed by Marc Klaw, A. L. Erlanger, and others. The Shuberts were in a position to rent theatres to producers discriminated against by the syndicate. Soon, however, the Shubert Corp. became a producing organization also. As its productions increased in number, fewer theatres were available to other producers. The Shuberts were then criticized for their harsh contracts and were said to have a stifling effect upon the American theatre. Lee Shubert died in New York City on Dec. 25, 1953. (M. Rs.)

SHUDRA (SUDRA), the fourth and lowest of the traditional varna or classes of Hindu society. The term does not appear in the earliest Vedic literature. In its first application it probably included all conquered peoples of the Indus civilization (*q.v.*) as they were assimilated as craftsmen and menials to the three-class Aryan society.

During centuries of social and economic diversification, the Shudra varna has become a wide spectrum of endogamous status groups, ranking from artisans down to untouchables (*q.v.*). These variations derive from the Hindu belief that certain behaviour patterns and occupations are polluting. This has given rise to a distinction between "clean" and "unclean" Shudra groups; for example, washermen, tanners, shoemakers, sweepers, and scavengers being relegated to untouchability.

See also CASTE (INDIAN); HINDUISM: *Social and Ethical Aspects of Hinduism.* (H. N. C. S.)

SHUFFLEBOARD (SHOVELBOARD; originally SHOVEBOARD), a game in which plastic or metal disks are shoved by the hand or with an implement so that they come to a stop on or within certain lines or compartments marked on the "board" or court (on a table, floor, or outdoor hard surface like concrete). It was popular in England as early as the 15th century, especially with the aristocracy, under the names shove-groat, slide-groat or shovel-penny. Some of the great country houses had boards of exquisite workmanship; that at Chartley hall, in Staffordshire, was over 30 ft. long, comprising 260 pieces. Shove-ha'penny, a later version of shovel-penny, in which a coin or disk is pushed along a polished board so that it stops between closely ruled lines, is still a popular game in English pubs.

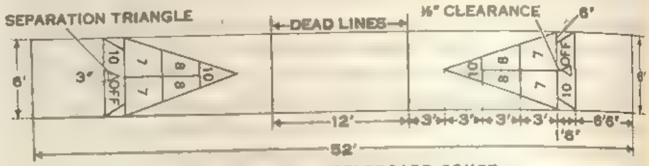

DIAGRAM OF SHUFFLEBOARD COURT

In modern times, a modified form of the old indoor game became popular among travelers on ocean liners as a deck game. For the shipboard version, called shuffleboard, courts of various designs were marked on the deck, with lined sections at either end, numbered one to ten; the section nearest the player, called ten-off, reduced scores by ten. The winning score was 50 points.

U.S. Game.—Shuffleboard was introduced about 1913 at Daytona Beach, Fla. So popular was the game that it spread rapidly through the United States, with each community devising its own rules of play. The modern form of shuffleboard was defined at St. Petersburg, Fla., in 1924, when Pierce V. Gahan, city recreation director, called a conference of all state shuffleboard clubs.

The rules adopted at that meeting defined the size and shape of courts (concrete or terrazzo, 6 × 52 ft.); the maximum length of the cues (6 ft. 3 in.) and the disks (either wood or composition, 1 × 6 in.; four red, four black). The rules also set forth the method of choosing partners, rotation of play, method of scoring and a list of penalties for violations of good sportsmanship, and introduced methods of strategic play. Though it is played by persons of all ages, and is a popular family game, shuffleboard is especially well-suited for elderly persons and others interested in light physical exercise.

Modern shuffleboard may be defined as a competitive game in which disks are propelled by means of cues onto a scoring diagram at the opposite end of a court, in order to score, to prevent opponent's scoring or both. It may be played by two persons (singles) or four (doubles). Interest is sustained as shots are made alternately by "red" and "black."

Strategy may play an important part in the game; to start, each player places his four disks in and not touching the lines of his half of the ten-off area, and a player's first shot (the red disk is shot first) may place a "pilot" or blocking disk in opponent's line of play just outside the scoring section, for example; or he may place a "sleeper" in the part of the scoring section nearest himself so that later he may "sneak" behind it a disk his opponent cannot reach. The blocking play may be met with a carom shot to remove the disk; or the opponent may elect to place a sleeper shot on his side of the court. In singles, when eight shots have been made from the head of the court, players move to the opposite end or foot of the court and continue play in turn until game score is made. In doubles, team players remain at the ends they occupy at the beginning of the game, though play alternates as in singles. Game may be 50, 75 or 100, as players desire. To count, disks must be entirely within scoring sections, clearing all lines. In match play (best two out of three games) the second game is started with a black disk.

During the depression of the 1930s, there was a revival of table shuffleboard in the United States. Played usually in amusement halls, it was often accompanied by gambling, and, being largely a game of chance, soon declined in popularity. (G. B. W.)

SHUMEN: *see* KOLAROVGRAD.

SHURUPPAK, an ancient Sumerian city, the site of which is at Tall Fa'rah in southern Iraq, about 12 mi. (19 km.) S of Nippur and now about 40 mi. (64 km.) E of the Euphrates, though in antiquity the river flowed past it. Brief excavations were made there at the beginning of the 20th century and again in 1931

Three levels of habitation were found, extending in time from the late prehistoric period to the 3rd dynasty of Ur (*c.* 2130–2021 B.C.). The most distinctive finds were ruins of well-built houses, and archaic cuneiform tablets with administrative records and lists of words, indicating a highly developed society already in being toward the end of the 4th millennium B.C.

Shuruppak was most celebrated, however, in legend as the scene of the Deluge, which destroyed all mankind except one survivor, Ziusudra, son of Ubar-Tutu, who reigned, according to the Sumerian king lists, for "18,600" (or "36,000") years in Shuruppak as the last king "before the Deluge." He was commanded by a favouring god to build an "ark" in which he rode out the disaster, afterward re-creating man and living things upon the earth, being himself removed from the haunts of mankind and endowed with eternal life. Ziusudra, whose name was preserved in Greek as Xisuthros, corresponds with Utnapishtim in the Gilgamesh epic (*q.v.*) and with Noah. *See* also FLOOD (IN RELIGION AND MYTH).

(C. J. G.)

SHUSHTAR, a town in Khuzistan *ostan*, Iran, about 50 mi. (80 km.) SE of Dezful on the Karun River about 15 mi. (24 km.) below the point where it debouches into the plains from the Bakhtiari Mountains. Pop. (1956) 18,527. The town is picturesquely situated on rising ground above the division of the Karun into two branches: the Ab-i-Shutait (west) and the Ab-i-Gargar (east). It is in decline, the inhabitants being attracted by the more prosperous oil towns; large parts of the town are deserted and ruinous. The bazaar is poor and the mosques are lacking in special architectural features except the oldest one dating from the time of the Abbasids. The citadel of Qal'eh-i-Salasil (Salasib), which formerly crowned the cliff above the river, has been demolished to make way for new urban development. Many of the stately houses of stone and brick have cellars, called *shewadan* or *zir zamin*, in which the inhabitants take shelter in the excessive summer heat which may reach 128° F (53° C). The town was once an important trade centre on the ancient road along the foot of the Zagros Mountains, dominating an extensive area rich in *deimi* (dry) and irrigated cultivation.

Water Works.—Shushtar is most famed for the great works constructed in ancient times for the disposal and use of the abundant water of the Karun River. The Band-i-Muhammad 'Ali Mirza, a stone dam with nine sluices dating from Sasanian times, which controls the flow of water, allows two-thirds to flow into the Ab-i-Shutait (the main arm of the Karun) and one-third into the Ab-i-Gargar (called Masruqan in the Middle Ages), an artificial channel through a cut more than 100 ft. deep. This is dammed by the Band-i-Gargar, a dam supporting a bridge which connects Shushtar with the suburb of Bulaiti to the east of the canal. It supplies water through tunnels on each side to drive flour mills and to generate electricity. The great Band-i-Qaisar barrage (the emperor's dike), on the Ab-i-Shutait west of the town, was about 600 yd. long and supported Valerian's Bridge, or Pul-i-Dezful. It first fell into ruin in the time of the Omayyads but was restored by the governor-general of Khuzistan, Muhammad 'Ali Mirza, the son of Fath Ali Shah, early in the 19th century. It was damaged by floods in 1885 and is now in ruins. There is also the Nahr-i-Dariyan (or Minau) Canal, which starts above the barrage in tunnels cut out of the rock on the western side of the town underneath the citadel, the purpose of which was to irrigate the Miyanab (the land between the two arms of the Karun).

According to tradition the Minau Canal was built by Darius I (the Great; d. 486 B.C.). Ardashir I (d. *c.* A.D. 240) began to construct the barrage after the mouth of the canal had dried up, probably because of river erosion. The barrage was completed under Ardashir's son Shapur I (d. 272) who is said to have used Roman prisoners captured with the emperor Valerian. The Ab-i-Gargar was first dug to divert the water of the main river; the Band-i-Qaisar was then constructed and the bed of the river above it was paved with huge stone slabs bound with iron to prevent further erosion. This paving was called *shadurwan*, a term also applied to the barrage itself.

See Laurence Lockhart, *Persian Cities* (1960). (H. Bo.)

SHUSTER, WILLIAM MORGAN (1877–), U.S. lawyer, civil servant, financial expert and publisher, who served as treasurer-general to the Persian government (1911–12), was born in Washington, D.C., on Feb. 23, 1877. He entered the Cuban customs service in 1899 but resigned in 1901 to become collector of customs at Manila. In 1906 he was appointed secretary of public instruction in the Philippines and a member of the Philippine commission (*see* PHILIPPINES, REPUBLIC OF THE: *History*).

When the Persian government appealed in 1910 to the U.S. government for advice and help in the reorganization of its financial system, Shuster, on the recommendation of Pres. William Howard Taft (under whom he had served in the Philippines), was chosen to head a small party of U.S. financial experts to achieve this end. On reaching Teheran in May 1911 Shuster and his colleagues were welcomed by the Persians and given every facility. Their endeavours, however, bore but little fruit, as they soon aroused the vehement opposition of Russia which went so far as to threaten armed intervention; in consequence the mission had to leave Persia in Jan. 1912. Shuster recounted the history of his mission in his book *The Strangling of Persia* (1912). In subsequent years Shuster, besides practising as an attorney, turned to publishing. He was president of the Century company of New York city (1915–33) and of Appleton-Century-Crofts Inc. from 1933 onward. He subsequently became chairman and chief executive officer of the latter company. *See* also PERSIAN HISTORY. (L. Lo.)

SHUVALOV, PETR ANDREEVICH, COUNT (1827–1889), Russian government official and ambassador, more successful as police official than as diplomat, was born in St. Petersburg on July 27 (new style; 15, old style), 1827, a member of an old noble family which had risen to imperial favour in the mid-18th century. He began his military service in 1845 and fought in the Crimean War as major of cavalry before entering upon a diplomatic career as a member of the Russian delegation to the Paris peace conference of 1856.

In 1857 Shuvalov was put in charge of the St. Petersburg police. His success there brought him to the post of director of the political police in the ministry of the interior (1861–64). After two years as governor general of the three Baltic provinces and commander of the Riga army corps, he returned to St. Petersburg in 1866 to be chief of staff of the gendarmerie corps and head of the political police, or "3rd section" of the imperial chancery. In this capacity he became the closest and most influential adviser of Alexander II. He wielded vast power as the leader of a conservative clique opposed to further liberal reform.

In 1873 Shuvalov was sent to London to reassure Great Britain over Russian advances in central Asia and to prepare the way for the marriage of the grand duchess Maria Aleksandrovna with the duke of Edinburgh (Alfred of Saxe-Coburg). His appointment as ambassador to London in 1874 apparently resulted from intrigues by his enemies at court and represented semidisgrace. Despite his easy charm, the count at first failed to distinguish himself in London. Before the Russo-Turkish War he weakened Russia's position by making unnecessary concessions to the British, whom he often found too clever for him. After the publication of the treaty of San Stefano (*see* EASTERN QUESTION) he concluded a secret convention with Lord Salisbury settling the principal Russo-British differences (May 29, 1878), making concessions for which he subsequently obtained his emperor's consent. At the congress of Berlin (*q.v.*) he was the principal Russian delegate, and the public storm in Russia which greeted the Berlin treaty induced the emperor to recall him in 1879. After living for nearly ten years in retirement, Shuvalov died in St. Petersburg on March 22 (N.S.; 10, O.S.), 1889. (D. MACK.)

SHWEBO, a town and district in the Sagaing Division of Burma. The town is situated on the railway about 50 mi. (80 km.) NNW of Mandalay. Pop. (1953) 17,842. It is of historic interest as the birthplace and capital of Alompra (Alaungpaya; d. 1760),

the founder of the last Burmese dynasty.

SHWEBO DISTRICT has an area of 7,605 sq.mi. (19,697 sq.km.) and a population (1962 est.) of 676,625. The district lies on the northern margins of the Dry Belt and stretches to and beyond the Upper Irrawaddy on the east where it now includes the old ruby mining area of Mogok. The main part of the district west of the Irrawaddy consists of a broad central plain drained by the Mu Chaung and extensively irrigated so that much rice is grown, with millets, sesamum, peanuts (groundnuts), peas, and cotton on the nonirrigated portions. The irrigation works are very old but fell into disrepair in King Thibaw's time (the 1880s), to be restored and extended from 1906 onward. The Mandalay-Myitkyina railway runs through the heart of this plain; elsewhere the country is one of wooded hills where the rainfall rises above the 25–40 in. (650–1,000 mm.) of the plain. (L. D. S.)

SHYOK, a large tributary of the upper Indus, which rises behind the Karakoram range near the Karakoram pass and after cutting across the range first flows toward the southeast and then takes a sharp turn to the northwest joining the Indus near Kiris, about 20 mi. S.E. of Skardu. The trans-Karakoram basin of the Shyok contains the plains of Depsang. From its source to its junction with the Indus the length of the river is 310 mi. and the total fall is 11,000 ft. Its catchment basin has an area of 13,000 sq.mi. The Gasherbrum glacier in the Karakoram region (*c.* 21 mi. in length) and the Khundam glacier drain into it. Its upper course is rushing and turbulent down a gorge but its middle course is broad and in places divides into many channels in an open valley. There the river is usually fordable although with some difficulty. Between Tertse and Unmaru there are seven distinct channels with an average depth of two feet. At the Turtuk bridge the river narrows to 70 ft. and in its lower course is again a furious rapid between precipitous cliffs. The Shyok's chief tributary, the Nubra, has its source in a large glacier, the Siachen, which lies across the Karakoram range. The principal peaks of this range between the Nubra and the Shyok are from 24,000 to more than 25,000 ft. in height. (K. S. AD.)

SIALKOT, a town and cantonment, and a district in the Lahore division of West Pakistan. The town lies on the northern bank of the Aik Nala, south of the Jammu hills, about 67 mi. N.E. of Lahore. Pop. (1961) 164,346 (including the cantonment). Popular legends attribute its foundation to Raja Sala, uncle of the Pandavas (of the epic, *Mahabharata*), and claim that it was refounded in the time of Vikramaditya by Raja Salivahan who built the fort, the remains of which, standing on a mound, are still to be seen. It has also been suggested that Sialkot is the site of ancient Sakala or Sagal, capital of the Indo-Greek Menander (Melinda) and Mihiragula, the Hun (d. 540). Originally the town proper was built around the fort. As a result of later expansion, however, several *abadis* (townships) sprang up nearby, of which the most important are Rangpur, Nekipura, Hajipura, Mianapura, Mubarikpura and Puran Nagar. Notable monuments include the tombs of several well-known Muslim scholars and religious leaders. The town also contains a shrine of the founder of the Sikh faith, Nanak, a temple erected by Raja Tej Singh. A Sikh temple established by Nanak himself lies in the eastern outskirts of the town. Of the modern buildings the municipal offices and town hall are built on the site of the fort. Educational institutions include Murray college, Jinnah Islamia college and the Government College for Women. There are two notable libraries and several parks. The town was the birthplace of the philosopher and poet Mohammed Iqbal. Sialkot is known for its manufactures of sports goods, surgical instruments, cutlery, rubberware and ceramics.

SIALKOT DISTRICT has an area of 2,067 sq.mi. and had a population (1961) of 1,596,383. It is an oblong tract of country occupying the submontane portion of the Rechna doab. The northern part is very productive, and the southern part, though less fertile, is irrigated by the upper Chenab canal. About nine-tenths of the cultivable area is under crops, the highest proportion of any district in West Pakistan. The principal crops are wheat, barley, maize (corn), millets and sugar cane.

The early history of Sialkot is closely interwoven with that of the rest of the Punjab. It was annexed by the British after the second Sikh war in 1849; and thereafter its area was considerably reduced, its present size dating from 1867. (K. S. AD.)

SIAM: *see* THAILAND.

SIAMESE LANGUAGE: *see* THAI LANGUAGE.

SIAMESE LITERATURE: *see* THAI LITERATURE.

SIAN (HSI-AN), capital of China's northwest province of Shensi and in early history the site of China's capital for a total of 970 years during the western Chou, the Ch'in, the Western Han, the Sui and the T'ang dynasties. Its earlier names were Changan and Siking and it reverted to its Manchu name Sian (meaning "western peace") in 1943. The city is situated on a broad loess terrace at the northern foot of the Tsinling Shan not far from the south bank of the Wei Ho. In the 14th century, Marco Polo, who called it Kenjanfu or Quengianfu, described it as a thriving trade centre. Its significant position derives from the productivity of the Wei plain and its natural topographic defenses, as well as its strategic command over radiating communications routes to Kansu and Turkistan in the west, Szechwan in the south, the Ordos desert in the north, Shansi and the Yellow plain in the northeast and east. It was there in 1936 that Chang Hsüeh-liang kidnaped Chiang Kai-shek in the "Sian incident" leading to a united front between Nationalist and Communist forces to resist Japan (*see* CHINA: *History*). However, during the Chinese-Japanese war, a strong Nationalist army was garrisoned at Sian, not only against the Japanese, but also to contain the Communists who had established a base at Yenan in north Shensi after 1935 under Gen. Hu Tsung-nan.

The city is surrounded by a rectangular wall, (approximately 3.1 mi. by 1.8 mi.) with a city gate on each side except the east which has two gates. Suburbs extend from each gate. The 1939 population of about 209,000 grew to 1,310,000 by 1957, because of industrial developments extending from the western suburbs. The expansion has resulted from new economic developments in China's northwest, including the completion of the trans-Tsinling railroad and the extension of the now doubled-tracked Lung-hai railroad passing Sian into Sinkiang.

Sian was one of the key cities in the Communist First Five-year plan. A small iron and steel mill was constructed, a cotton textile combine set up, and a new thermal electric power plant built which supplies nearby cities and Sian with power. Also constructed were a cement plant, with a seamless steel tube rolling mill, and a moderate-size chemical plant.

Historically important, the city contains temples, tombs and monuments. The collection in the Shensi provincial museum (formerly the Pei-lin) is noteworthy, and the Nestorian tablet discovered in 1625 was housed there. Sian is the seat of Northwestern university and Medical college, and the location of the Northwestern Institutes of Art and Music. (H. J. WS.)

SIANG FRONTIER DIVISION is the central of the five divisions constituting the North East Frontier Agency of the Republic of India. It is through the heart of this division that the Dihang river (a section of the Brahmaputra) passes in a series of stupendous gorges from the plateau of Tibet to disgorge on the valley plain of upper Assam less than 1,000 ft. above sea level. Navigability on the Brahmaputra ceases at Pasighat; from there a rough track runs alongside of the valley west of the river, eventually passing into Tibet and linking with the motor road to Lhasa. The Abor is the principal tribe living in this division. They were first visited by the British in 1826. From 1848 they carried out numerous raids and outrages on the neighbouring territory and several expeditions were sent against them. From 1912 to 1913 the territory known as the Abor hills formed part of the Sadiya frontier tract (from Sadiya, near the confluence of the rivers Lohit and Dibang with the Dihang) and was loosely administrated by the government of India. Eventually it was included in the North East Frontier Agency (*q.v.*). (L. D. S.)

ŠIAULIAI, the fourth largest town in Lithuania (now the Lithuanian Soviet Socialist Republic, U.S.S.R.), and administrative centre of a district of the same name. Pop. (1959) 59,722. A Christian church was erected there in 1445, but the town began to expand only during the latter part of the 19th century when a

large leather and footwear industry was established there. After 1918, when Lithuania regained its independence, Šiauliai became a major economic centre, and it contains 85% of Lithuania's leather industry (tanning) and 60% of the footwear industry, as well as two-thirds of the flax processing. Chocolate and sweetmeats, meat and fish conserves, and other food products and beverages are produced. The town is a major rail junction and is on the Riga-Kaliningrad road. During World War II Šiauliai was partly destroyed, but it has been rebuilt, with wide avenues and modern buildings.

SIBAWAYH, the nickname of Abu Bishr 'Amr ibn 'Uthman ibn Qanbar (*c.* 760–793), the most celebrated Arabic grammarian. He was a Persian client of an Arab tribe, and studied under Khalil (*q.v.*) in Basra. He wrote the first known full-scale Arabic grammar, called *al-Kitab fi'l nahwi,* on which all subsequent Arabic grammars were based. The book defines three parts of speech—noun, verb, and particle—and explains *i'rab,* or accidence, as applied to nouns and verbs. Then the parts of speech and their use are dealt with in great detail, with supporting quotations from the Koran and from Arabic poetry.

Editions of the *Kitab* are by H. Derenbourg, *Le Livre de Sibawaihi* (1883); and by G. Jahn, with commentary and German translation, two volumes (1895–1900).

See also G. L. Flügel, *Grammatische Schulen der Araber* (1862); C. Brockelmann, *Geschichte der arabischen Litteratur,* vol. 1 (1898), suppl. vol. 1 (1937). (J. A. Hd.)

SIBELIUS, JEAN (Johan Julius Christian Sibelius) (1865–1957), the greatest symphonic composer of Scandinavia and one of the most original figures in 20th-century music, was born at Hämeenlinna, Finland, on Dec. 8, 1865. He became a pupil at the Suomalainen Normaalilyseo, the first Finnish-speaking school, where he came into contact with Finnish literature and in particular the *Kalevala,* the mythological epic of Finland, which remained for him a constant source of inspiration. Many of his symphonic poems, such as *Pohjola's Daughter* and *Luonnotar,* draw on this source.

Although intended for a legal career he soon abandoned his law studies at Helsinki, devoting himself entirely to music. At first he planned to become a violinist. Under the guidance of Martin Wegelius he composed much chamber and instrumental music. He adopted the name Jean, which he used throughout his professional career in preference to his baptismal names. In his mid-twenties he left Finland to continue his studies in Berlin and Vienna, where his teachers included Robert Fuchs and Karl Goldmark.

On his return to Finland a performance of his first large-scale orchestral work, the *Kullervo* Symphony (1892), created something of a sensation. This and succeeding works, *En Saga,* the *Karelia* music and the *Four Legends,* established him as Finland's leading composer. In 1897, before the appearance of his First Symphony, the Finnish Senate voted him a small life pension in recognition of his genius. His tone poem *Finlandia* was written in 1899 and revised in 1900.

© KARSH, OTTAWA

JEAN SIBELIUS, PHOTOGRAPHED IN 1949

In the first decade of the 20th century Sibelius' fame penetrated the continent. Busoni, whose friendship he had made in Helsinki as a student, conducted his Second Symphony in Berlin and Henry Wood and Granville Bantock introduced his works to English audiences, Bantock commissioning his Third Symphony. With this work Sibelius turned his back on the national romanticism of the Second Symphony and Violin Concerto and moved toward the more searching and uncompromising mode of utterance of *En Saga* and the Fourth Symphony. After World War I he published his greatest works, the last three symphonies and *Tapiola,* but then lapsed into the long silence of his last years. Rumours of an Eighth Symphony (promised for performance in the early 1930s) and even a Ninth Symphony were unfounded. No manuscripts survived his death at Järvenpää on Sept. 20, 1957.

The 1930s saw a vogue for Sibelius prompted by such writers as Cecil Gray and Constant Lambert in England and Olin Downes in the U.S. Despite a reaction against this vogue in the following generation, Sibelius retained his firm hold over the musical public. Although his inspiration is intimately connected with the Scandinavian landscape, it is not primarily as a nature poet that he is remembered. His achievement both in the symphonic poems and the seven symphonies lies principally in his remarkable mastery of form. As Gerald Abraham pointed out, the first movement of the Third Symphony has the clarity of construction of a Haydn or Mozart first movement, yet its organic unity and architecture even surpasses its models. It was in this capacity for organic growth that the secret of his genius lay.

SIBENIK (Italian Sebenico), a port of the Socialist Republic of Croatia and headquarters of Sibenik *srez* (district), Yugoslavia, lies at the mouth of the river Krka on the Adriatic Sea, 190 mi. (306 km.) SE of Rijeka by road. Pop. (1961) 24,800. The town is overlooked by fortifications and has some fine Renaissance architecture including the loggia and part of the beautiful cruciform Roman Catholic cathedral (1431–1536) built entirely of stone. Sibenik is the seat of a Roman Catholic bishop (since 1298) and of an Orthodox bishop. It is a naval base and steamship station and is connected with Zagreb by rail. It exports bauxite, timber, and wine. Electric power is supplied by the celebrated falls of Krka (11 mi. [18 km.] inland).. Insecticide powder and calcium carbide are manufactured, there are woolen mills and oil refineries, and the wood of the smoke tree (*Cotinus coggygria*) is prepared for dyeing purposes. Fishing and sponge and coral gathering are other occupations.

Sibenik is first mentioned in 1066 and it was in Hungarian hands from 1180 to 1322 and from 1351 to 1412 when it passed to Venice. By the peace of Campo Formio in 1797 it was awarded to Austria and in 1805, under Napoleon I, became attached to the kingdom of Italy. From 1814 to 1918 it was part of the Austrian Empire, after which it was incorporated into Yugoslavia. During World War II Sibenik was occupied by the Italians and then by the Germans. (V. De.)

SIBERIA (Russian Sibir'), a vast region of the U.S.S.R. composing the whole of northern Asia between the Ural Mountains (west) and the Pacific Ocean (east) and extending southward from the Arctic Ocean (Kara Sea, Laptev Sea, and East Siberian Sea) to the hills of central Kazakhstan and the frontiers of the U.S.S.R. with China and Mongolia. Within the Soviet Union a small part of Siberia in the southwest (Tselinnyy [Tselinny] Kray and Semipalatinskaya [Semipalatinsk] and Vostochno-Kazakhstanskaya [East Kazakhstan] *oblasts*) is administratively incorporated into the Kazakh Soviet Socialist Republic, while the rest of the region belongs to the Russian Soviet Federated Socialist Republic. The administrative areas adjacent to the Ural Mountains (Tyumenskaya [Tyumen], Sverdlovskaya [Sverdlovsk], Chelyabinskaya [Chelyabinsk], and Kurganskaya [Kurgan] *oblasts*) and those along the Pacific coast (Khabarovskiy [Khabarovsk] and Primorskiy [Primorski] *krays* and Amurskaya [Amur], Magadanskaya [Magadan], Kamchatskaya [Kamchatka], and Sakhalinskaya [Sakhalin] *oblasts*) are not now officially considered as part of Siberia, the former group belonging to the Urals region and the latter being known as the Far East. The rest is divided into western and eastern Siberia by a line running meridionally somewhat west of the Yenisey (Yenisei) River. The constituent administrative divisions are: Altayskiy (Altai) Kray, Kemerovskaya (Kemerovo), Novosibirskaya (Novosibirsk), Omskaya (Omsk), and Tomskaya (Tomsk) *oblasts* in western Siberia; and Krasno-

yarskiy (Krasnoyarsk) Kray, Irkutskaya (Irkutsk) and Chitinskaya (Chita) *oblasts*, and the Yakut, Buryat, and Tuva Autonomous Soviet Socialist republics in eastern Siberia. The total area of Siberia in the wider sense is 5,330,896 sq.mi. (13,807,037 sq.km.) (or more than a quarter of the Asian continent and more than 60% of the territory of the U.S.S.R.), in the narrower sense 4,374,475 sq.mi. (11,330,600 sq.km.). There were 32,471,380 inhabitants in the whole region in 1959, including 21,466,775 in Siberia in the narrower sense (western 10,159,437, eastern 6,960,535, far eastern 4,346,803), 9,112,337 in the Urals part, and 1,892,268 in the Kazakh part. The population is sparse, chiefly concentrated in the west and south, more than half urban and overwhelmingly Russian. This article deals with the historical development of the whole region. (*See* also UNION OF SOVIET SOCIALIST REPUBLICS and the separate articles on the administrative divisions.)

Early History.—It is still not established whether man came to Siberia from Europe or from central and eastern Asia. The earliest Paleolithic finds, in the Altai area of southern Siberia, are of the Mousterian type. Finds of the later Paleolithic Age are numerous and are concentrated, apart from the Altai area, along the upper reaches of the Yenisei (the Minusinsk Basin) and near Lake Baikal. The Neolithic Age has been mainly studied in two areas: near Lake Baikal, which was then the centre of a hunting culture stretching from the Yenisei to the middle reaches of the Amur; and along the lower Amur and the Pacific coast, where a totally different fishing culture existed, connected with Manchuria, China, and Korea. About 2000 B.C. the inhabitants of the Altai-Minusinsk area first began to make use of copper. The people of this culture were of the Europeoid race, while those living to the east and to the north were predominantly Mongoloid. Soon the tribes of the Baikal-Lena area, who are regarded as the ancestors of the Paleo-Asiatic Yukaghir, also started using copper and bronze—possibly under Chinese influence—though they remained primarily hunters. They were later partly displaced and partly assimilated by the Tungus tribes, which, coming from the Amur area, spread over a vast territory in eastern Siberia and probably brought with them the use of reindeer. The bronze culture which centred in the Altai-Minusinsk area and reached as far west as the Urals shows not only a further development of animal husbandry but also the beginnings of agriculture. The working of bronze was stimulated by the existence of rich local ores and attained high technological and artistic levels. Around 1000 B.C. Chinese influence began to be felt. Subject to strong influences from China and central Asia, southern Siberia developed rapidly both economically and politically, while the Paleo-Asiatic and Tungus tribes of the northern forests and tundra lagged far behind. In the 7th–2nd centuries B.C. the Minusinsk Basin was the home of an advanced sedentary culture involving complicated systems of irrigation developed by the people who are tentatively identified as the Ting-Ling of the Chinese chronicles; they were the first users of iron in Siberia. The rest of southern Siberia was at this time inhabited by nomadic tribes, probably Iranian (Scythian) in the west, belonging to the large belt of similar cultures stretching from the steppes north of the Black Sea to Mongolia and characterized by the "animal style" of ornamentation. The famous Pazyryk burial mounds of the Altai area, on the right bank of the Bol'shoy Ulagan (Bolshoi Ulagan) River, show strong signs of Persian influence.

From the 3rd century B.C. the whole of southern Siberia belonged in turn to the Turkic-Mongol Huns and to the various Turkic states centred in Mongolia. From the 6th century A.D., when the local Altai Turks established their khanate, the Turks also predominated ethnically, partly assimilating the neighbouring Samoyed and partly driving them north. The central part of southern Siberia, around the Minusinsk Basin, was the home of the Kirgiz, ancestors of the present-day Khakass and Altai peoples as well as of the Kirgiz of central Asia. Further east, in the Baikal area, lived the Kurykans, perhaps the ancestors of the Yakuts, while the steppes of northern Kazakhstan were inhabited by the nomadic Kipchaks (Kumans), who later became the chief ethnic component of the Kazakh people. From the 10th century the Turks were overpowered by the Mongols, whose states, however, remained unstable until the creation of the great Mongol Empire by Genghis Khan. Almost the whole of Siberia was incorporated into this empire, at least nominally. The primitive peoples in the far north were scarcely affected, but for the comparatively high civilization of southern Siberia the Mongol conquest had fatal consequences. The larger part of Siberia belonged to the domain of the great khan himself, but western Siberia was included in the domain of his son, Juchi, and commonly known as the Golden Horde (*q.v.*). The Mongol conquest strengthened the Turkic element in the Ob' (Ob) River area, hitherto predominantly Ugrian, where the Turks later became known as Siberian Tatars. They were the dominant element in the Sibir khanate which emerged after the breakup of the Golden Horde in the mid-15th century. (*See* MONGOL EMPIRES.)

Russian Colonization (1581–1890).—Siberia is first mentioned in Russian sources in the 11th century, and from the 12th century the merchants of Novgorod traded with the tribes of the lower Ob area, the main attraction being furs. In 1581 a small band of Cossacks under Ermak Timofeevich, a mercenary in the service of the Stroganov family (merchants who had large property in the western Urals), undertook an expedition to western Siberia and within a year conquered the Siberian khanate. From then on the opening up and annexation of Siberia by the Russians proceeded rapidly. Small Cossack units, using the river systems of the Ob, Yenisei, and Lena rivers, spread throughout the whole of northern and parts of southern Siberia, establishing fortified towns in strategic positions (Tyumen in 1585, Tobolsk in 1587, Tomsk in 1604, Kuznetsk in 1617, Krasnoyarsk in 1628, Yakutsk in 1632, Okhotsk on the Pacific coast in 1649, Albazino [Albazin] on the Amur in 1651, and Irkutsk in 1652) and imposing their administration upon the surrounding areas for the purpose of collecting tribute for Muscovy. There was a major reverse in the Amur area, where the Russian advance met with Chinese resistance; and, according to the Treaty of Nerchinsk in 1689, most of the area was declared Chinese, though in fact it remained a no-man's-land between Russia and China.

Kamchatka Peninsula was annexed in 1699, but only by the Aigun and Peking treaties in 1858 and 1860 respectively did China renounce all claims to the Amur area and the Pacific coast between the mouth of the Amur and Korea. In the southwest the khan of the Kazakh Middle Hundred exchanged Dzungarian (Kalmyk) suzerainty for Russian in 1740, and the Altai area was annexed in 1756, when the Dzungarian state, to which it had belonged since the breakup of the Mongol Empire, passed under Chinese rule.

Cossack officers, Muscovite officials, monks, and merchants were the first Russian explorers of Siberia, and the Cossack Semen Dezhnev was the first to sail through the Bering Straits in 1648. The exploration was put on a systematic and more scientific basis in the 18th century, when the Russian Academy of Sciences organized several expeditions, mainly to northern Siberia and the Far East. In the 19th century, the task of studying Siberia's physical and human geography was largely taken over by the Imperial Russian Geographical Society, assisted by Siberian businessmen.

The administration of annexed Siberia was directed by the Siberian office in Moscow (later in St. Petersburg) from 1614 till 1763. Several provinces were formed during the 18th century, and as a result of the administrative reform of 1822, prepared by Count M. M. Speranski, two governors-general were appointed: one for eastern Siberia with his seat in Irkutsk and another for western Siberia with his seat first in Tobolsk, then, from 1838 in Omsk. The western Siberian provinces of Tobolsk and Tomsk were in 1882 exempted from the jurisdiction of the governor-general in Omsk, who retained authority only over the Kazakh steppe. Finally a viceroy was appointed in 1884 for the newly annexed territories in the Far East together with the old Russian possessions on the Pacific coast.

At first Russian economic activity was limited to the collection of tribute, which was paid by the local inhabitants in furs as it had been paid to the Mongols; Siberian furs were one of the main assets of the Muscovite state's trade with Western Europe

However, Russian agricultural colonization on a small scale went on parallel with the military occupation in the late 16th century and throughout the 17th, its primary aim being to feed the military and administrative personnel. An extensive network of stagecoach and mail routes was developed by the government and many settlers were employed in this service.

Silver mining on a small scale was started in 1698 and in the next century two important industrial areas developed in Siberia: the Altai, where silver and copper were mined and smelted; and the Nerchinsk area in Transbaikalia (Zabaykal'ye), with silver and lead mining. With the decline of the fur trade, mining became the main economic activity in Siberia, the principal entrepreneurs being the state and the imperial household. The supply of labour was largely guaranteed by a system of bondage which tied workers permanently to the mines and metal plants. Forced labour by convicts was also persistently practised by the government, though it was highly unproductive and the majority of convicts managed to escape, usually to become bandits. Gold mining, in contrast, which developed in many areas from the 1830s, was mainly in the hands of private enterprise employing free labour.

The emergence of an indigenous class of industrialists and the banishment to Siberia of large numbers of revolutionary intellectuals (beginning with the Dekabrists in 1826 and participants of the Polish insurrection of 1830–31) combined to produce a small but vocal Siberian intelligentsia and the development of a Siberian regional consciousness. The regionalists demanded the removal of all discriminatory measures arising from Siberia's colonial status, with regional self-government.

Most indigenous Siberian peoples had resisted Russian conquest and submitted only after a long struggle and attempts to move away from the Russian centres into the interior. Indeed, the most warlike and least accessible of them, the Chukchi, considered themselves independent until they were finally subdued in the 1930s. The impact of the Russians upon the indigenous peoples was twofold. The smaller and more primitive tribes succumbed to exploitation by the merchants and corrupt officials, to poverty and to diseases brought by the colonists. On the other hand, larger peoples such as the Yakuts, Buryats, and Kazakhs adjusted themselves to the new situation and began to profit from the material benefits of the colonization. The internal institutions and way of life of the indigenous peoples were generally not interfered with by the Russian authorities, and there was remarkable religious tolerance, which led to the spread in the 17th and 18th centuries of Buddhism among the Buryats and Islam among the Kazakhs, while most of the other peoples became at least nominally Christian.

The Modern Period.—The great event that marked the transition of Siberia (with its vast natural resources) from a traditionalist to a modern economy was the construction of the Trans-Siberian Railway. The original line was begun at both ends, at Chelyabinsk and at Vladivostok, in 1891 and was completed in 1905. It facilitated the influx of new colonists, first in connection with the construction itself, then under the colonization plan introduced by P. A. Stolypin, president of the Council of Ministers with the portfolio of the interior), to reduce the rural overpopulation in European Russia. Siberian agriculture, which had never known peasant serfdom or large private estates, quickly developed American-type farming methods, specializing in grain and particularly in butter, the production and marketing of which were largely in the hands of cooperatives. Coal mining was started in several places along the line to supply the needs of the railway, and the railway repair shops were the first engineering plants in Siberia.

Siberia took an active part in both the 1905 and 1917 revolutions, and events of the Russian civil war there were most dramatic. An autonomous Siberian government was formed after the overthrow of the Soviet power in the region early in 1918 but was soon superseded by the government of Adm. Aleksandr Vasilievich Kolchak (*q.v.*), in Omsk, who was proclaimed the supreme ruler of Russia by the leaders of the "White" armies. After the defeat of Kolchak, the Far Eastern Republic was set up in 1920 in the area east of Lake Baikal as a buffer state between Soviet Russia and Japan; in reality, however, this was one of the first "people's democracies" and was incorporated into the Soviet state as soon as the Japanese interventionists left Vladivostok in 1922. Indigenous authorities set up by the Kazakhs, Buryats, and Yakuts during the civil war were suppressed and several ostensibly autonomous republics and regions were established instead with the purpose of remolding the population's way of life according to the general Soviet pattern.

Industrial development, interrupted by revolution and civil war, was resumed during the first five-year plan period (1928–32), when the Ural-Kuznetsk coal mining and iron and steel combine was built in southwestern Siberia, largely by the forced labour of deported peasants. Forced-labour camps spread throughout Siberia during the 1930s, the most important being the Dalstroi (Far Eastern Construction Trust) system in the extreme northeast, and the Noril'sk (Norilsk) area on the lower Yenisei, both concerned with the mining of nonferrous and precious metals. World War II gave a new impetus to the industrial development; many enterprises were evacuated from the west and Siberia, together with the Urals, became the industrial backbone of the Soviet war effort.

Agriculture, on the contrary, greatly suffered from collectivization in 1930–33 and was largely neglected until the Virgin Land Campaign of 1954–56, when the southwest of Siberia (including northern Kazakhstan) was the principal area to be cultivated. Siberia figured prominently in the seven-year plan (1959–65), with the main emphasis on the construction of large thermal and hydroelectric power stations, electrification of the Trans-Siberian Railway as far as Irkutsk, and a further increase in the production of steel.

SIBIU (Ger. HERMANNSTADT, Hung. NAGYSZEBEN), a town of the Rumanian People's Republic, in the Braşov region, situated north of the Turnu Roşu pass at the foot of the Transylvanian Alps, 1,361 ft. above sea level and 72 mi. S.S.E. of Cluj. Pop. (1963 est.) 100,659, including a high proportion of German and Hungarian origin.

The old town centre, which retains a medieval appearance, is divided into the upper town on a terrace and the lower town on the banks of the river Cibin, a tributary of the Olt, the two parts of the town being connected by steep alleys and flights of steps. There are remains of the town walls and towers. The Lutheran church dates from the 14th century and the town hall was built in the 15th century. The Brukenthal museum, with the largest art collection in Transylvania, is in a handsome baroque building (1778–85) containing a library and paintings which include Dutch, Flemish and German masters as well as Rumanian. In addition there are important collections of ecclesiastical antiquities, ethnography, folk art and natural science. Sibiu is the seat of a Lutheran bishop and of a Rumanian Orthodox metropolitan. It has teachers' training colleges and secondary schools including the Brukenthal school dating from the Reformation. The town is a cultural centre and has a state theatre and a philharmonic orchestra.

Sibiu is connected by road and rail to Braşov and to Bucharest (through the Turnu Roşu pass). It is a commercial and manufacturing centre producing machinery, textiles, chemicals, inks, leatherwork, footwear, and building materials.

Originally a Roman colony (Cibinium), Sibiu was refounded as Hermannsdorf by Saxon (German) colonists in the 12th century. It was destroyed by the Tatars in 1241. In the 14th century it became an important administrative and commercial centre of the German communities in Transylvania, and suffered much in the wars with the Turks. In 1699 it became subject to Austria.

SIBLEY, HIRAM (1807–1888), a founder and second president of the Western Union Telegraph company, was born at North Adams, Mass., Feb. 6, 1807. When he was 16 his family moved to western New York where he later operated a foundry and machine shop and was in 1843 elected sheriff of Monroe county.

Visiting Washington, D.C., Sibley met Samuel F. B. Morse, the telegraph inventor, and helped obtain congressional backing for construction of the first telegraph line in 1844. Recognizing the need for a national telegraph system, Sibley and other Rochester, N.Y., citizens, in 1851, formed the New York and Mississippi Valley Printing Telegraph company, which bought 11 small lines north of the Ohio river. In 1856 the company was renamed The Western Union Telegraph company.

Sibley became president of Western Union later that year. Under his leadership, the first transcontinental telegraph line was built in 1861, to help hold the western states in the Union in the Civil War and to develop the west.

Sibley began building a line to Europe via Russian America, the Bering strait and Siberia in 1865. When he was in St. Petersburg, negotiating to buy right-of-way, the tsar's nephew offered to sell what is now Alaska to Western Union. Sibley refused, but launched a campaign to persuade the United States to buy it, which was done in 1867. The expedition was abandoned when the first permanently successful transatlantic cable was laid in 1866, but it had mapped and reported Alaska's vast resources.

Sibley retired as president of Western Union in 1865 and became a builder of railroads in the middle west and south and owner of vast farm holdings. Part of his fortune was used to establish the Sibley College of Mechanic Arts Engineering (later Mechanical Engineering) at Cornell university, of which with Ezra Cornell (*q.v.*) he was one of the incorporators. He died in Rochester on July 12, 1888. (G. P. O.)

SIBSAGAR, a town and district of Assam, India. The town lies on the Dikhou river, about 10 mi. from its confluence with the Brahmaputra. Pop. (1961) 15,106. Established by the Ahom king Siba Singha (1714–44), Sibsagar was named after the large water tank built by Queen Ambika Devi in 1720. Among notable buildings are the temple of the god Shiva and the Vishnu and Gouri Devi temple, both erected during Siba Singha's reign. Sibsagar college is affiliated to Gauhati university. The town is a station on the North-East Frontier railway and lies on the national highway.

Sibsagar District, has an area of 3,453 sq.mi. and had a population (1961) of 1,508,390. It is situated between the south bank of the Brahmaputra, the western boundary of Nagaland and the Mikir and North Cachar hills on the south and west. The alluvial plains of the mid-Brahmaputra valley are dissected by a large number of tributaries. One-third of the district is forested and, besides providing valuable timber, the forests are abundant in wild life. Tea, rice, pulses and mustard-seed are grown on the plains. Oil deposits are exploited near Rudra Sagar and Moran in the northeastern part of the district; tertiary coal is mined at Naginimara on the Nagaland border. Sibsagar district was the heart of the Ahom kingdom and Gargaon (Nazira; 8 mi. from Sibsagar), the original capital of the kingdom, contains the ruins of forts and royal palaces. Jorhat, the last capital of Ahom, has agriculture, engineering and other colleges. An earthquake on Aug. 15, 1950, followed by large-scale floods, caused many deaths and widespread destruction throughout the district. (M. Ba.)

SIBYL (Sibylla), a prophetess in Greek legend and literature. The word is of unknown, probably Asiatic, derivation and appears first in the Greek philosopher Heraclitus (*c.* 540–*c.* 480 B.C.) of Ephesus as a proper name. The typical legend represents her as a woman of prodigious old age uttering predictions in ecstatic frenzy, but she is always a figure of the mythical past, and her prophecies, in Greek hexameters, are handed down in writing. In the 5th and early 4th centuries B.C. she is always referred to in the singular Sibylla is treated as her proper name and she is apparently located in Asia Minor (at Erythrae in Ionia or Marpessus near Troy) in uncertain antiquity. From the late 4th century the number of sibyls is multiplied; they are localized traditionally at all the famous oracle centres and elsewhere, particularly in association with Apollo, and are distinguished by individual names, sibyl being treated as a title. Varro in the 1st century B.C. lists ten (Persian, Libyan, Delphic, Cimmerian [in Italy], Erythraean, Samian Cumaean, Hellespontine, Phrygian, Tiburtine) and others could be added from other sources. Virgil in the *Aeneid* gives a vivid description of the consultation of Deiphobe, the sibyl of Cumae, by Aeneas, on the lines of a traditional consultation of the Delphic oracle. According to legend, this sibyl was granted by Apollo the gift of prophecy and a life of as many years as the number of grains of dust in her hand, but she did not ask for youth as well, so she gradually withered away almost to nothing. Finally she was hung up in a bottle, saying only that she wished to die.

A famous collection of sibylline prophecies, usually called the Sibylline Books, was according to legend offered for sale to Tarquinius Superbus, the last of the seven kings of Rome, by the Cumaean sibyl. He refused to pay the sum demanded for the nine books, so the sibyl burned three books, and then three more, before finally selling him the remaining three at the price she had originally asked for all nine. The books were thereafter kept in the temple of Jupiter on the Capitoline hill under the care of a priestly college, to be consulted in emergencies only by order of the senate. After the burning of the Capitol in 83 B.C. a new collection of Sibylline Books was compiled. The last recorded consultation of them was ordered by Julian the Apostate in A.D. 363, and they were officially destroyed under Stilicho (d. 408).

A Judaean or Babylonian sibyl was credited with writing the Judaeo-Christian Sibylline Oracles (*q.v.*). The sibyl came thus to be regarded by some Christians as a prophetic authority comparable to the Old Testament: hence the references to her in Christian literature, such as the *Dies irae*, where she is mentioned in the same breath as King David (*teste David cum sibylla*). The most notable examples of sibyls in art are those by Michelangelo in the Sistine chapel of the Vatican (*see* Fresco Painting).

See Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, 2nd series, vol. 2, col. 2073–2183 (1923). (H. W. Pa.)

SIBYLLINE ORACLES. During the Hellenistic age and under the early Roman empire, literary-minded Jews and Christians were impressed by the respect paid to the various sibyls (*see* Sibyl) as seeresses predicting the future, and they proceeded to create a collection of oracles, written in Greek hexameters in which the sibyls would first prove their reliability by predicting the recent past and then go on to predict the downfall of kings or empires in the immediate future; along the way they would set forth doctrines peculiar to Hellenistic Judaism or to Christianity. Not unnaturally, the Jewish apologist Josephus and such Christian apologists as Justin and Theophilus were greatly impressed by the way in which their doctrines were confirmed by such external testimonies. Both Theophilus and Clement of Alexandria referred to the sibyl as a prophetess apparently no less inspired than the Old Testament prophets; their pagan contemporary Celsus scathingly referred to Christians as "sibyllists." Those who criticized sibylline inspiration often attacked the crudity of the hexameters, relying on the theory that the gods could speak good Greek. In the Byzantine period no fewer than 12 of these compositions were collected in a single manuscript (in 14 books; ix and x are lost); an incomplete text of this collection was first published in 1545.

Modern scholars have been able to assign dates to the various oracles, largely by comparing the known sequence of events with what the oracles predicted. When real events are being described the oracle-writer is describing the past; when errors begin, he is predicting the future. This principle of dating has the merit of simplicity, though it can be too rigidly applied.

In any event, the oldest oracle is probably found in book iii (lines 97–294 come from 150–100 B.C.); books iv and v are Jewish works of the reign of Domitian (A.D. 81–96); books i–ii (originally a single book) and vi–vii are Christian; book viii reflects Christian

antagonism to the empire in the reign of Marcus Aurelius (A.D. 161–180). Books xi–xiv, considerably later, are Jewish; the Church Fathers do not quote from any of them.

SICANI (English SICANS), the ancient inhabitants of western Sicily. Sikanie, the Greek name for Sicily in the *Odyssey* (xxiv, 307), appears to be a doublet of Sikelia, the usual Greek name (from Sikeloi, the Siculi or Sicels). Archaeologically there is no substantial difference between Sicans and Sicels in historical times; but ancient authorities distinguish the two peoples and assign a different origin to them. The Sicans, who were believed to be Iberians from Spain, were driven by the invading Sicels into the western and southern parts of the island (Thucydides, vi, 2). The Greek colonists of Gela and Acragas (Agrigento) on the south coast had to fight Sican wars; the people of this part of the interior retained more cultural independence of the Greeks than the Sicels of eastern Sicily did. In the Roman period no distinction is drawn between Sicans and other inhabitants of Sicily. (T. J. DN.)

SICILIAN VESPERS, the massacre of the French with which the Sicilians began their revolt of 1282 against Charles I (*q.v.*), the first king of the Angevin dynasty of Naples-Sicily, so-called because it began with a riot in a church outside Palermo at the hour of vespers on Easter Monday, March 30, 1282. The Sicilians were aggrieved by oppressive taxation and by the new regime's neglect of their interests; and the Aragonese king Peter III, whose wife Constance was heiress of the former Hohenstaufen kings of Sicily, was sponsoring a conspiracy, organized with Byzantine subsidies by Giovanni da Procida, a Sicilian exile at his court, for a rising in Sicily to break out when Charles launched his long-expected attack on the Byzantine Empire. The rising, however, broke out prematurely: some French soldiers at vespers in the church of S. Spirito behaved disrespectfully to a Sicilian woman and were killed by the congregation; the people of Palermo followed suit, massacring 2,000 French men, women, and children in the night of March 30–31; and the other towns of Sicily rose likewise (Messina not till April 28). Communes were proclaimed, and the Sicilians tried to put themselves under the protection of Pope Martin IV, suzerain of the Sicilian kingdom, who, however, refused to approve them. The Aragonese, to whom the Sicilians next appealed, landed at Trapani on Aug. 30.

The War of the Sicilian Vespers ensued. The Angevins, Charles I and his successor Charles II (*q.v.*), were supported by the papacy, by the Italian Guelphs, and by Philip III of France, who launched his disastrous campaign against Aragon in 1285 in an attempt to put Charles of Valois on Peter III's throne. The excommunicated Aragonese were helped by the Italian Ghibellines and profited especially from the naval genius of Ruggiero di Lauria (*q.v.*). The separation of the Aragonese and Sicilian crowns on Peter's death (1285) between his sons Alfonso III and James (I of Sicily) was followed, after the former's death (1291), by the latter's accession to Aragon as James II; and James, by the Treaty of Anagni (June 1295), made peace with the papacy, France, and the Angevin, to whom he renounced Sicily. The Sicilians, however, then took James's younger brother Frederick III (*q.v.*) as their king; and, despite Aragon's adhesion to his enemies, Frederick maintained himself in his kingdom, which he finally secured by the Treaty of Caltabellotta (Aug. 31, 1302). The papacy's authority was impaired by the long insistence of Martin IV and his successors on identifying themselves with the Angevin cause in the vain hope of preventing partition of the original Sicilian kingdom.

See S. Runciman, *The Sicilian Vespers* (1958).

SICILY (SICILIA), the largest island (9,830 sq.mi. [25,460 sq.km.]) in the Mediterranean sea, is separated from the "toe" of Italy by the Strait of Messina (2–10 mi. wide). It is shaped like a triangle, and on its shape its ancient name, Trinacria, was based. Its three points are Cape Peloro (Punta del Faro) in the north in the Strait of Messina; Cape Passero in the southeast; and Cape Boeo near Marsala in the west. Administratively the Lipari, Aegadian and Pelagie islands and the isles of Pantelleria and Ustica are part of Sicily, making the total area 9,926 sq.mi. (25,708 sq.km.). Under the Italian constitution of 1948 Sicily became a semiautonomous region; its capital is Palermo.

This article is divided into the following sections and subsections:

I. PHYSICAL GEOGRAPHY

1. Physical Features.—The mountains of Sicily as part of the Tertiary Alpine-Himalayan fold system are a continuation of the Atlas mountains of northwest Africa and the Apennines of Italy.

Northern Sicily is dominated by a group of mountain chains that extend from the Strait of Messina to the Torto river. The easternmost of these, the Peloritani mountains (Pizzo di Polo 4,219 ft. [1,286 m.]), is closely connected structurally with the Calabrian Apennines and is crystalline in composition. The Nebrodi mountains, farther east (Mt. Soro 6,060 ft. [1,847 m.]), and the Madonie mountains (Pizzo Carbonara 6,486 ft. [1,977 m.]) are limestone; the latter range is known for its underground drainage systems and provides drinking water for the city of Palermo. These mountains stand like a high wall between the north shore of Sicily and the interior and are traversed only by roads. Western Sicily is characterized by limestone massifs, some shaped like promontories or peninsulas (*e.g.* Mt. Pellegrino outside Palermo). The central and southwest part of Sicily consists of the "sulfurous plateau" between the Platani and the Salso rivers, a landscape of gypsum, sulfur and clay, desolate and poor; east of the Salso the plateau changes to low uplands between the towns of Gangi and Caltagirone, known as the Erei mountains. Their highest point (3,109 ft.) is near Enna. In the southeast the low Iblei mountains (Mt. Lauro 3,236 ft.), a complex tableland with low peaks, slope gradually to the sea. Eastern Sicily is dominated by the great volcanic cone, Mt. Etna (*q.v.*; 10,705 ft.); to the south the Catania plain extends as far as the foothills of the Iblei mountains. Along the coastline there are numerous small plains and low terraces.

2. Climate.—Sicily is warm in winter and summer. Near the coast the mean January temperatures are more than 10° C. (50° F.) and even inland more than 4° C. (40° F.). In summer the temperature rises considerably: near sea level the mean temperatures are 24° to 26° C. (75° to 79° F.) with extremes of 38° C. (100° F.). The effects of the heat are accentuated by the low

rainfall. The rainy season is confined to the late autumn and winter; the total rainfall on the north and south coasts and in much of the interior is less than 25 in. (635 mm.), in the extreme south only 15 in. (380 mm.). The result of this low rainfall, combined with deforestation and failure to systematize the mountain torrents, is that most of Sicily suffers from severe lack of water. The frequent, dry sirocco wind from the south is a scourge. (G. Kh.)

3. Vegetation and Animal Life.—Man's influence has greatly changed the natural vegetation. In the lower belt *Stipa tortilis* steppe and carob and olive-tree shrub, *maquis, garigue,* and woods of holm oak, cork oak, or aleppo pine cover the places free from cultivation. Papyrus grows along the Anapo and Ciane rivers. The submontane belt is broken up by cereal cultivation into scattered woods of pubescent oak, chestnut or mixed mesophilous woods. Native plane tree occurs along eastern rivers. Beech woods in the montane belt pass gradually into the formations of the alpine belt with juniper (*Juniperus hemisphaerica*), *Berberis aetnensis* or *Astragalus siculus* and the volcanic ash vegetation of Mt. Etna. (R. E. G. P.-S.)

The animal life has much in common with southern Italy, which is to be expected, but it also has some animals in common with Sardinia, for example, the ringed plover, black vulture and griffon vulture, which are not found in Corsica or southern Italy. Sicily shares the pratincole and the black and bearded vultures with Spain and the Balkans, and also shares the black wheatear with Sardinia and Spain. (Ma. Bu.)

II. ARCHAEOLOGY

The pre-Hellenic inhabitants of Sicily are called by classical authors Sicani or Siculi, and these two names have been used as conventional designations for those early cultures which have been revealed since Paolo Orsi began investigation in 1889. The term Sicanian is applied to that period of the Stone Age which followed the Paleolithic exemplified in the remarkable rock engravings of the cave of Addaura near Palermo (first published in 1953); the term Siculan is applied to the Chalcolithic, to the Bronze and to the Iron Ages, the first Siculan period being Chalcolithic, the second being Bronze Age, the third, from 900 to 700 B.C., being Iron Age and the fourth from *c.* 700 B.C., being the period when the native civilization was hybridized with the Greek. The earlier cultures tended to persist in "retarded" communities.

1. Sicanian Period.—The Sicanian period is known principally from fortified villages such as those at Stentinello and Matrensa. Stone implements from these places were of poor quality, and there were no other objects of interest except the pottery. This was handmade and baked in an open fire. Its surface is blackish-gray, and the geometrical ornament upon it, which appears merely incised, has in parts a strange regularity produced by real stamps—not by puncture by bone awls—a phenomenon unique at that early time. Later various styles of painted pottery are found; apparently later still are the incised wares of the Conca d'Oro and of Moarda, which are associated with the bell-beaker culture.

2. First Siculan Period.—The principal sites of this period are those of Castelluccio, Melilli, Monte Racello, Monte Tabuto, Vallelunga and Monte Salia. The typical burial was in a rock-hewn chamber, the construction varying according to the nature of the ground, so that at Monte Tabuto the dead were buried in disused flint-mines, while at Monte Racello natural caverns were enlarged for the purpose, and actual surface graves were even formed out of slabs on the top of the broken ground. At Castelluccio, however, which may be taken as the standard case, the circular or elliptical chambers were hewn in a vertical face of rock and entered by a short horizontal corridor.

Each chamber contained many skeletons. They were invariably buried in the squatting position, accompanied by a small number of weapons and ornaments and a regular equipment of pottery. The weapons and implements were sometimes of stone, especially flint, sometimes of copper in primitive forms as if the neolithic period was only just past and hardly forgotten. Of personal ornaments there were few. Of pottery, all handmade, there were three kinds: a rough household ware; pots of a better clay coated with a red or yellow slip; and—far the most important—a ware covered either with a cream-coloured or dark-red slip on which very simple geometric patterns were executed in dark brown. Nothing very closely resembling it is known anywhere else.

3. Second Siculan Period.—The second Siculan period of the full Bronze Age is represented at its best by the cemeteries of Thapsos (modern Magnisi), Plemmirio, Milocca and Cozzo Pantano close to Syracuse and by Caldare near Agrigento. All these contain Mycenaean imports, of which the earliest are clearly to be dated as Mycenaean III A. (*See* Aegean Civilization.) Bronze swords from the same sites are also of Mycenaean origin or influence and prove the existence of a considerable direct trade with the Aegean. All the cemeteries consisted of rock-hewn tombs, a natural evolution from the rock tombs of the first Siculan. The roof of the chamber, however, was sometimes of tholos (beehive) form, which again recalls Aegean precedents. Inside it was usually elliptical; a raised bench cut in the rock ran round it, and niches were often hewn in the walls. Within this chamber the dead were buried as if seated at a stately banquet. The size of the great food basins was remarkable; they were often 2½ or 3 ft. in height.

The native pottery was made principally in a gray-faced ware ornamented with molded strips or with a few sparsely incised lines; there was also a yellow-faced ware. Painted ware is unknown. The shapes are very few—a high stand, a biconical cup with side handles, a conical cup, a jug and one or two large water jars. For-

eign trade added the amphora, pyxis, pedestaled cup and stirrup-handled vase and gave a great impetus to metalworking. Swords, daggers and even basins may have been imported, but the various hoards of bronze objects show that a great quantity of native work must have existed. The tombs, however, were systematically ransacked for metals after the Roman time. Another proof of foreign influence was the introduction of the fibula (large safety pin), which appears at Cozzo Pantano for the first time. Early fibulae were of two types, the plain violin bow with bamboo knots and the harp-shaped or elbowed fibula, each made in a massive form.

The four cemeteries near Syracuse must be assigned on the evidence of the foreign imports to the 14th and 13th centuries B.C. Caldare, farther inland, may be later.

4. **Intermediary Period.**—Next in chronological order come the large necropolises like Pantalica, Grammichele, Caltagirone and Monte Dessueri which span the gap between the Bronze and Iron Ages, the later graves in them belonging entirely to the Early Iron Age. On Orsi's system they are to be classed as intermediate between the second and the third Siculan. The form of the tomb had already begun to be modified, the number of burials in each grave was smaller, and the tomb furniture was later in character. This was especially perceptible in the personal ornaments; the fibulae changed considerably, for in place of the primitive violin bow the simple rounded bow was predominant and more sophisticated forms, like the eyed harp fibula, began to appear.

In addition to arm rings and finger rings and mirrors of bronze there were also found, though rarely, gold rings, silver armlets and silver rings. Rectangular bronze razors came into use, like those known in Italy but of different origin. There were no weapons, perhaps because of the rifling of the graves, but flame-shaped and leaf-shaped bronze knives occurred. The native pottery was very varied in form at that time, the best of it being in a ware faced with red hematite.

5. **Third and Fourth Siculan Periods.**—On a site like Pantalica, with a range of several centuries, the Iron Age (Orsi's third period) begins without any striking changes. Modifications occurred in the types of the fibulae and there was a gradual, but quite perceptible, deterioration of the pottery. All the Bronze Age types of fibulae gradually gave way to later forms, of which the most general and popular was the two-eyed serpentine, which continued in use down to 500 B.C.

The first appearance of this fibula marks the beginning of the Early Iron Age, and if the contents of tombs belonging to this stage are isolated and examined separately from the rest, then certain definite characteristics begin to appear. The old Siculan civilization of the great days survived in a much impoverished form. The architecture had lost all its beauty and elaboration of detail. Within a very simple chamber the dead were no longer seated at a banquet but extended at full length on the ground with their heads resting on a block of stone; and the objects buried with them consisted of little but a few small water jars and trumpery pots. Everything of interest in Siculan life from the 9th to the 5th century B.C. is either a Greek importation or the direct imitation of a Greek original, known either from traders or, after *c.* 730, from Greek settlers.

From a number of sites, the most important of which were Finocchito, Lentini (the ancient Leontini) and Licodia Eubea, were obtained examples of geometrically painted vases, the earliest of which are of pure Dipylon style, while the latest are a hybridized product which may be termed Greco-Siculan.

The introduction of these new models led to the imitation of purely Greek shapes by the native potters, so that *oenochoai* and *askoi* (vases) were copied in the rough country ware, and to a closer study of decorative designs, which resulted in the production of a new kind of white-faced ware with geometrical patterns painted upon it. This gradually improved in technique until it reached its high-water mark in the late third and early fourth Siculan periods. The Greco-Siculan ware continued in use until it was finally replaced about 500 B.C. by purely Greek imported vases. For this whole period, the stratigraphic investigations at Megara Hyblaea (1949 onward) yielded valuable results.

(D. R.-M.; A. W. V. B.; X.)

6. **Classical Archaeology.**—After having long been relegated to secondary rank in art as merely a provincial area in relation to Greece proper, Sicily in recent years has steadily emerged as an artistic entity in its own right. The earliest works of sculpture confirm the literary tradition of a "Daedalic" school (*see* GREEK ART: *The Greek Archaic Period*); and the art of the later archaic period, including clay statues and statuettes, pursued a course of development parallel to that of Greece, with which it clearly remained in contact while achieving considerable freedom in style and technique. "Nowhere more forcibly than in its mouldings does the architecture of the West stand forth as a vigorous, original architecture, based on, but independent from, the forms of Greece, the Aegean, and Asia Minor" (L. T. Shoe, *Profiles of Western Greek Mouldings*, American Academy in Rome, 1952). Down to the beginning of the 5th century B.C., when the traditional terracotta revetments were superseded by marble, the coloured adornment of the temples showed features distinctly characteristic of this area. Throughout the 5th and the early 4th centuries, the issues of coins exhibited an exuberance and a standard of artistic excellence all their own; clearly the die cutters stood in close relation to the gem engravers and, in some cases, were identical with them. Although the rich ceramic yields of the cemeteries consist largely of imported products, first of the Corinthian and later of the Athenian potteries, there is an abundance of local wares as well, revealing several clearly defined schools of the 4th century and later; some of the painted decoration suggests the influence of the Western Greek theatrical plays. Excavations at the Phoenician town of Motya (*q.v.*) and many Sicel towns throw light on the background of the Greek cities. Sicily is rich in remains of villas and other buildings of the Roman period; and the architecture and mosaic art of late antiquity are nobly represented at Piazza Armerina (*see* below: *Roman Sicily*). *See* further GREEK ARCHITECTURE; GREEK ART; ROMAN ART; NUMISMATICS: *Greek Coins*. For some of the outstanding architectural monuments, *see* AGRIGENTO; GELA; SEGESTA; SELINUS; SYRACUSE.

(A. W. V. B.; X.)

III. HISTORY

At the coming of the Greeks three peoples occupied the island of Sicily: in the east the Sicels or Siculi (*q.v.*), who gave their name to the island but were reputed to be late-comers from Italy; to the west of the Gelas river, the Sicani (*q.v.*); and in the extreme west the Elymians, a people to whom a Trojan origin was assigned, with their chief centres at Segesta (*q.v.*) and at Eryx (Erice) with its temple of Aphrodite. The Sicels spoke an Indo-European language; there are no remains of the languages of the other peoples.

Thucydides says (vi, 2) that the Greeks were preceded in Sicily by Phoenicians, who established trading stations on promontories and small islands all round the coast. But no material remains of such early settlements have been found. Thucydides adds that when the Greek colonization began, the Phoenicians withdrew to the western corner of the island, where they had the Elymians as allies and the support of Carthage. There they had three towns, Motya, Soloeis and Panormos (Palermo). Hostilities between Greeks and Phoenicians are not heard of earlier than the Cnidian attempt to settle on the westernmost point of Sicily *c.* 580 B.C. (*see* below).

1. **Greek Sicily, to 413 B.C.**—Mycenaean traders had already visited Sicily and the Lipari Islands between the 15th and 13th centuries B.C., and the fibula was introduced by direct or indirect importation from the Aegean (*see* above, *Archaeology*). There was then a long period when Sicily was beyond the horizon of Greek sailors (the few references in the *Odyssey* need be no older than the early period of colonization). Toward the middle of the 8th century intercourse was resumed, and the first colony was planted *c.* 734 B.C. at Naxos on the east coast by Chalcidians from Euboea, who had already founded Cumae near Naples. (Precise dates for the foundation of the Sicilian colonies are given by Thucydides; and though some modern scholars suppose that these are based only on calculations made about 300 years after the era of the first colonies, they may be accepted as approximately correct.) In the year after Naxos, according to Thucydides, the Corinthians

founded Syracuse, the greatest city of ancient Sicily, and at the same time occupied Corcyra (Corfu) which commanded the way thither. The east coast was rapidly occupied: the Chalcidians founded other colonies at Leontini and Catania (both *c.* 729) and held the Straits of Messina by the foundation of Zancle (later Messana; modern Messina) on the Sicilian side and Rhegium (Reggio di Calabria) on the Italian side (both probably in the last quarter of the 8th century). The Megarians founded Megara Hyblaea (*q.v.*) at about the same time as Leontini. On the south coast the earliest colony was Gela, a joint Cretan and Rhodian settlement (*c.* 688). The southeastern corner was occupied by the secondary Syracusan foundations of Acrae (*c.* 663), Casmenae (*c.* 643) and Camarina (*q.v.; c.* 599), the last of which was the most important. In or about 628 the Megarians founded Selinus (*q.v.*), the westernmost Greek city of Sicily, facing the coast of Africa. Between Gela and Selinus was Akragas or Acragas (Roman Agrigentum), a Geloan colony, the last of the foundations of the great age of colonization (580), which rapidly rose to be the second city of Sicily. On the north coast there was long only a single Greek city, the Chalcidian Himera (*q.v.*) (*c.* 649). About 580 the Cnidians founded Lipara, after an unsuccessful attempt to settle in the neighbourhood of Eryx. The defeat of this attempt by the Elymians and Phoenicians marks the first recession of the tide of Greek settlement, and the Greeks never succeeded in occupying the western part of the island. The mountainous centre remained in the hands of Sicels and Sicani, who were increasingly hellenized in ideas and material culture.

After the foundation of the colonies, little is known of them until the 5th century. They prospered materially, building temples whose remains, at Syracuse, Akragas and Selinus, are among the finest monuments of archaic and classical architecture. Their sculpture and other arts were vigorous, though provincial and largely dependent on impulses from mainland Greece. There is some reason to believe that they had a colonial economy, producing food (corn, sheep and cattle, fish) and importing manufactured objects (of which clay vases are the chief survivors) from Greece —in the period before 550 B.C. mainly from Corinth, afterward from Athens. The broad acres of the colonies and; at Syracuse and probably also elsewhere, the use of Sicel serfs gave rise to a life of easy circumstances and, in the 5th century, to the great wealth of the tyrants (*see* below). The fine series of Sicilian coins began toward the middle of the 6th century (*see* NUMISMATICS: *Greek Coins*). The poet Stesichorus of Himera, who retold many of the stories of epic with a new spirit reflected in archaic vase paintings, belonged to this period.

There were many tyrants—unconstitutional monarchs—in the 6th century, especially in those towns which were pressed by the growing hostility of the Carthaginians; the most famous was Phalaris (*q.v.*) of Akragas; in general, however, this was a period of aristocratic or oligarchical constitutions. The early 5th century saw tyrants in most cities. The tyranny of Gela was founded in 505, and Hippocrates (498–491) carried his arms over most of eastern Sicily; his successor Gelon (*q.v.*) took Syracuse in 485 and transferred his seat thither, enlarging the city with men from other colonies and settlers from old Greece. This is the beginning of Syracusan rule over Greek Sicily. The families of Gelon and of Theron (tyrant of Akragas, 488–472) were united by marriage. Theron seized Himera, expelling its tyrant Terillus, who with his son-in-law, Anaxilas of Rhegium (494–476), ruler also of Zancle, formed a coalition against Gelon and Theron and invited Carthaginian support. The Carthaginian invasion was defeated in a single battle at Himera (480), and its commander, Hamilcar Barca, son of Hanno (his mother was a Syracusan), was killed. The victory opened a short period of brilliant prosperity for Greek Sicily. The courts of Gelon and of his brother and successor Hieron I (*q.v.;* 478–467) and of Theron were visited by Pindar, Aeschylus, Simonides of Ceos and Bacchylides; the leading artists of Greece were commissioned to make rich offerings at Olympia and Delphi; fine temples were built as thank offerings for the victory of Himera. Hieron extended his activity to Italy, where he protected Locri against Anaxilas of Rhegium and defeated the Etruscans at sea off Cumae (474). The darker side of the tyrants' rule is seen in forced movements of population from city to city and in the destruction of many Greek cities (*e.g.,* Megara Hyblaea). Hieron refounded Catania with great splendour, under the name of Etna, after expelling the Chalcidian inhabitants; he set up his son Deinomenes as king and hoped that this would be a refuge for his family; but within a few years of his death the original inhabitants returned, and the new settlers carried the name Etna inland to Inessa, on the slopes of Mt. Etna.

These tyrannies were short-lived. Theron's power fell to pieces when his son Thrasydaeus succeeded. Hieron's brother Thrasybulus was overthrown by a combined movement of Greeks and Sicels (466). They were succeeded by uneasy democracies in most cities, Syracuse still taking the lead. The Sicels then for the first time formed a united power, under Ducetius, who founded a new city at Palici in the plain of Catania and became a serious threat to Syracuse and to Akragas. He was defeated and his political work largely undone, except for the foundation of Cale Acte (Caronia) on the north coast. The Sicels did not again attempt to combine as a force, but their hellenization continued; many Sicel cities began to coin on the Greek model.

The extent of the native contribution to Sicilian culture is disputed. The Sicels may have had a worship akin to the cult of Demeter and Persephone, which was widely spread over both Greek and native Sicily; but the localization of the rape of Persephone at Enna is due to Greek influence. The material culture of the Greek colonies shows no Sicel elements. Some words of Italic origin were taken into the Greek dialects of Sicily; and the racy comedies of Epicharmus and the mimes of Sophron may show some kinship of spirit to Italian comedy. The main Sicilian contribution to Greek literature and thought in the 5th century was in the development of rhetoric and its transference to Athens by Gorgias (*q.v.*). A more original philosopher was, it appears, Empedocles (*q.v.*) of Akragas, who was poet, physician, politician and perhaps something of a charlatan.

The Athenians looked for allies in Sicily at least as early as 458/457, when they made a treaty, still extant, with Segesta. At the beginning of the Peloponnesian War they sought for means to cut off supplies from Sicily to their enemies and allied themselves with the Ionian cities, Leontini and Rhegium. In 427–426 they sent a small squadron to Sicily but accomplished little. In 415, during the "peace of Nicias," they were led by expansionist ideas, expressed by Alcibiades, to send a large force in answer to an appeal for help from Segesta and Leontini. The ultimate object of this expedition was the subjection of the whole of Sicily. The Athenians were received with suspicion, even by some of their allies, and Naxos and Catania were the only Greek cities to support them; they also had help from some of the Sicels. The utter defeat of the Athenian force under the walls of Syracuse in 413 (*see* PELOPONNESIAN WAR; SYRACUSE) was achieved in part by the arrival of the Spartan leader Gylippus and was followed by the dispatch of small forces from Syracuse and other Sicilian cities to help the Spartans against Athens.

2 Carthaginian Wars.—The failure of Athens left the field open for Carthage, with whom the Athenians had sought an alliance. In 409 an army under Hannibal, son of Gisgo, landed to support Segesta against Selinus. Selinus and Himera were taken and destroyed; Himera, where Hannibal sacrificed 3,000 of the citizens to avenge his grandfather Hamilcar, was never rebuilt but was replaced by a new town, Thermae Himerenses. In 406 Akragas fell also. Dionysius (*q.v.*) the Elder rose to power at Syracuse as its military leader but was forced to evacuate the populations of Gela and Camarina before he could obtain a peace with the Carthaginians which left him in control of Syracuse. For the rest of his life he fought a series of inconclusive wars with the Carthaginians. In 397 (possibly 398) he took Motya, the chief Phoenician city in Sicily (which had a considerable Greek element within its walls) and seemed on the point of driving the Phoenicians out of the island. But in the following year the tables were turned by the arrival of a Carthaginian fleet under Himilco in the harbour of Syracuse. A pestilence, spread among Himilco's troops from the marshes of Lysimelia, assisted Dionysius in winning a complete victory, which confirmed his position as ruler of Syracuse and mas-

ter of most of Sicily. But he had to fight other Carthaginian wars in 392–391, 383–378, and 368–367, the year of his death. In the peace made in 378 the boundary between Greek and Carthaginian Sicily was fixed at the river Halycus (Platani). Selinus and Himera remained on the Carthaginian side, Akragas became a frontier town. Lilybaeum (the modern Marsala) replaced Motya in 396 and became the chief centre of the Phoenicians in Sicily.

Dionysius used his position as defender of Greek Sicily to build up a personal power which anticipates the Hellenistic monarchies in many ways. The transplantations of population and refoundations of cities which had been a feature of the rule of Gelon and Hieron continued. New foundations were Tauromenium (modern Taormina), which replaced Naxos, and Tyndaris on the still rather empty north coast. The Sicel towns of Hadranum (Adrano) near Mt. Etna and Halaesa on the north coast were also refounded, one by Dionysius, the other by his Sicel ally Archonides of Herbita. Dionysius made considerable use of the forces of Sicel allies, and the distinction of barbarian from Greek Sicily begins to disappear. He also employed large mercenary forces, some of them from Gaul and Spain.

After 390 Dionysius intervened in the affairs of the Greeks in Italy, in alliance with the Lucanians, who had recently pressed down into the "toe" of Italy. Locri was his base in Italy. He took Rhegium and Caulonia and defeated the forces of Crotona and Thurii, thus winning control over most of Greek Italy, except Tarentum (modern Taranto). He sent a fleet into Etruscan waters which plundered the wealthy temple at Caere. His activities in the Adriatic were of more permanent importance; he planted a colony at Lissus (modern Lezhe in Albania) to control the crossing of the Ionian sea; he helped the Parians to colonize the Dalmatian island of Pharos (Hvar); and Syracusan exiles founded Ancona, perhaps with his consent and backing.

Dionysius had as ally the Molossian Alcetas and engaged Illyrian mercenaries. These activities appear to have been in preparation for intervention in the affairs of Greece.

The rule of Dionysius at Syracuse depended on foreign mercenaries and on secret police, and many of the typical features of Plato's and Aristotle's accounts of Greek tyrants are no doubt derived from him. But he was well served by efficient ministers, such as Philistus the historian (who however went into exile). He was himself a poet and, like earlier tyrants, kept a court, which was visited by Plato and other philosophers and poets. He made Syracuse the greatest power in the Greek world, and it became the largest and, probably, the most populous of Greek cities, with its extensive fortifications (*see* SYRACUSE). His power, however, did not long survive him. Most of his conquests in Italy fell to the Lucanians and Bruttii, and at Syracuse his son Dionysius the Younger, after ruling from 367 to 356, was expelled by his uncle Dion (*q.v.*). Dion was killed in 354, and there followed ten years' confusion: fighting in Syracuse between Dionysius the Younger and the citizens; tyrannies in other cities; and renewed danger from Carthage, allied with Hicetas, tyrant of Leontini and rival of Dionysius. The Syracusans appealed to their mother city Corinth, and Timoleon (*q.v.*) came as a deliverer. He freed the cities from tyrants and defeated the Carthaginians at the battle of the Crimisus (probably 341); but the boundary remained at the river Halycus. Timoleon's reputation was high because he restored the democracy at Syracuse and retired after his work of liberation was done; but his settlement did not last long after his death (*c.* 336). The Carthaginians, who had already played off one city against another, continued this policy, while the Greeks consumed their energies in struggles between would-be tyrants. They found another leader in Agathocles (*q.v.*), one of the ablest soldiers of the time, who made himself tyrant of Syracuse in 317. Akragas, strengthened by Syracusan exiles, stood out again as the rival of Syracuse; and Hamilcar son of Gisgo won many Greek cities to the Carthaginian alliance and blockaded Agathocles in Syracuse. Agathocles broke through and carried the war into Africa, where he won many successes (310–307), but was finally completely defeated and had to flee back to Sicily. In spite of this defeat he maintained his position at Syracuse and made peace on the old terms with Carthage. He formed marriage alliances with Ptolemy I of Egypt and with Pyrrhus of Epirus, who married his daughter. He was the first of the Sicilian tyrants to take the title of king. He died in 289. In spite of his reputation for treachery and massacre, his rule was remembered as a period of prosperity.

In the troubles which followed Agathocles' death, his disbanded Campanian mercenaries seized Messana and called themselves the Mamertini (*q.v.*), children of Mamers or Mars. The fortunes of Sicily were thus linked with Rome. Another new foundation of that time was Phintias (Licata) at the mouth of the southern Himeras, named after the Agrigentine tyrant Phintias (289–279). New Carthaginian attacks called forth another liberator from overseas, Pyrrhus (*q.v.*) of Epirus, but his Sicilian war (278–276) was a mere interlude between the two acts of his war with Rome. When he left Sicily to fight for Tarentum against Rome, he had to fight his way out through Carthaginians and Mamertini, the latter already allied with Rome; he said, in true prophecy, that he left Sicily as a wrestling ground for Romans and Carthaginians.

The Syracusans chose as leader Hieron II (*q.v.*), who defeated the Mamertini and came near to capturing Messana; he won the title of king of Syracuse (*c.* 270). In 264 his attack on the Mamertini led to the intervention of Rome and the First Punic War (264–241). The war began as a three-cornered event between Rome, the Carthaginians and Hieron; but in 263 Hieron turned from the Carthaginians to Rome and formed an alliance to which he remained loyal for the rest of his long life. The Romans were thus free to use Greek Sicily as a base for war with Carthage. The western part of the island, both Greek and Phoenician, suffered greatly in this long war (for its course *see* PUNIC WARS). By the treaty which ended it Carthage ceded to Rome all its possessions in Sicily, which thus became the first Roman province (241). Hieron retained possession of eastern Sicily, south of Messana. His rule was able and enlightened, and his financial enactments, particularly his corn laws, were taken over when Rome incorporated his kingdom. This period of peace was the last golden age of free Sicily: the great theatre at Syracuse was rebuilt by Hieron, and Theocritus sang the pastoral pleasures of his native island and offered an encomium to Hieron (*c.* 275).

3. Roman Sicily.—At the outbreak of the Second Punic War Hieron held firm to the Roman alliance, but after his death in 216 his grandson Hieronymus repudiated it. Hieronymus was overthrown by revolution at Syracuse (215), but the city had to stand a siege from the Romans. The great fortress of Euryelus (*see* SYRACUSE: *Archaeology*) perhaps took its final form then, under the inspiration of Archimedes, though there is no reason to doubt that its construction began in the time of Dionysius I. Syracuse was taken and sacked in 212, Akragas after a further campaign in 210. The whole of Sicily then became Roman.

Little is known of the early organization of the Roman province. It was governed by a praetor sent out yearly from Rome, who after the annexation of Syracuse had his capital there. Two quaestors were appointed, one with his office at Syracuse, the other at Lilybaeum. The province included a number of free cities: Messana, Tauromenium and Netum (Noto) were allied cities (the two latter had probably taken the Roman side in the Second Punic War); a number of others, including allies from the First Punic War, were also free—Segesta, Halicyae, Panormos, Halaesa and Centuripe. The rest paid tithes to the Roman people according to the law of Hieron, which was extended to the whole island. Sicily had long had a surplus of corn for export, and Livy records occasional dispatch to Rome as early as the 5th century B.C.; the island now became the granary of the Roman people. The rolling country of the central part of the island was suitable for pasture and cultivation on a large scale, in *latifundia* (landed estates), and slave gangs were introduced on the estates both of rich Sicilians and of Roman citizens. Hence rose the two great slave revolts of the second half of the 2nd century B.C., the first, led by Eunus, from 135 to 132, with Enna and Tauromenium as its centres, the second from 104 to 100; both periods of internal and external stress at Rome. The settlements after these two wars by Publius Rupilius (131) and Manius Aquilius (99) modified the organization of the province.

In spite of slave wars and the burden of Roman provincial

governors and tax farmers, Sicily was not unprosperous under the Roman republic. It was free from external dangers; and even the unprivileged cities kept their own laws, magistrates and assemblies, and provision was made for lawsuits between Romans and Sicilians and between Sicilians of different cities. There seems not to have been much commercial exploitation; tax collecting was normally in the hands of the Greeks themselves, not of Roman *publicani;* and smallholdings continued to be the rule in many cities. The wealth of the cities, both free and tributary, may be seen from the speeches of Cicero in prosecution of Gaius Verres (*q.v.*), who in three years' governorship (73–71) had plundered widely, with especial attention to works of art. He also failed to defend the province against pirates.
